Contents

Quick tasks for getting started with Microsoft 365 compliance

2/18/2021 • 10 minutes to read • Edit Online

If you're new to Microsoft 365 compliance and wondering where to start, this article provides guidance on the basics and prioritizes important compliance tasks. This article will help you quickly get started with managing and monitoring your data, protecting information, and minimizing insider risks.

This article is also helpful if you're figuring out how best to manage risks, protect your data, and remain compliant with regulations and standards with a newly remote workforce. Employees are now collaborating and connecting with each other in new ways, and this means your existing compliance processes and controls may need to adapt. Identifying and managing these new compliance risks within your organization is critical to safeguarding your data and minimizing threats and risks.

After you've completed these basic compliance tasks, consider expanding compliance coverage in your organization by implementing additional Microsoft 365 compliance solutions.

Task 1: Configure compliance permissions

It's important to manage who in your organization has access to the Microsoft 365 compliance center to view content and perform management tasks. Microsoft 365 provides administrative roles specific to compliance and for using the tools included in the Microsoft 365 compliance center.

Start by assigning compliance permissions to the people in your organization so that they can perform these tasks and to prevent unauthorized people from having access to areas outside of their responsibilities. You'll want to make sure that you've assigned the proper people to the **Compliance data administrator** and the **Compliance administrator** admin roles before you start to configure and implement compliance solutions included with Microsoft 365. You'll also need to assign users to the Azure Active Directory global reader role to view data in Compliance Manager.

For step-by-step guidance to configure permissions and assign people to admin roles, see Permissions in the Security & Compliance Center.

Task 2: Know your state of compliance

It's difficult to know where to go if you don't know where you are. Meeting your compliance needs includes understanding your current level of risk and what updates may be needed in these ever changing times. Whether your organization is new to compliance requirements or has deep experience with standards and regulations that govern your industry, the single best thing you can do to improve compliance is to understand where your organization stands.

Microsoft Compliance Manager can help you understand your organization's compliance posture and highlight areas that may need improvement. Compliance Manager uses a centralized dashboard to calculate a risk-based score, measuring your progress in completing actions that help reduce risks around data protection and regulatory standards. You can also use Compliance Manager as a tool to track all your risk assessments. It provides workflow capabilities to help you efficiently complete your risk assessments through a common tool.

For step-by-step guidance to get started with Compliance Manager, see Get started with Compliance Manager.

IMPORTANT

Security and compliance are tightly integrated for most organizations. It's important that your organization addresses basic security, threat protection, and identity and access management areas to help provide a defense in-depth approach to both security and compliance.

Check your Microsoft 365 Secure Score in the Microsoft 365 security center and completing the tasks outlined in the following articles:

- Security roadmap - Top priorities for the first 30 days, 90 days, and beyond
- Top 12 tasks for security teams to support working from home

Task 3: Enable auditing for your organization

Now that you've determined your organization's current state and who can manage compliance functions, the next step is to make sure you have the data to conduct compliance investigations and generate reports for network and user activities in your organization. Enabling auditing is also an important prerequisite for compliance solutions covered later in this article.

Insights provided by the audit log are a valuable tool in helping to match your compliance requirements to solutions that can help you manage and monitor compliance areas needing improvement. Audit logging must be enabled before activities are recorded and before you can search the audit log. When enabled, user and admin activity from your organization is recorded in the audit log and retained for 90 days, and up to one year depending on the license assigned to users.

For step-by-step instructions to turn on auditing, see Turn audit log search on or off.

Task 4: Create policies to alert you about potential compliance issues

Microsoft provides several built-in alert policies that help identify admin permissions abuse, malware activity, potential external and internal threats, and information governance risks. These policies are turned on by default, but you may need to configure custom alerts to help manage compliance requirements specific to your organization.

Use alert policy and alert dashboard tools to create custom alert policies and view the alerts generated when users perform activities that match the policy conditions. Some examples could be to use alert policies to track user and admin activities affecting compliance requirements, permissions, and data loss incidents in your organization.

For step-by-step guidance to create custom alert policies, see Alert policies in the security and compliance center.

Task 5: Classify and protect sensitive data

To get their work done, people in your organization collaborate with others both inside and outside the organization. This means that content no longer stays behind a firewall—it can roam everywhere, across devices, apps, and services. And when it roams, you want it to do so in a secure, protected way that meets your organization's business and compliance policies.

Sensitivity labels let you classify and protect your organization's data, while making sure that user productivity and their ability to collaborate isn't hindered. Use sensitivity labels to enforce encryption and usage restrictions apply visual markings, and protect information across platforms and devices, on-premises and in the cloud.

For step-by-step guidance to configure and use sensitivity labels, see Get started with sensitivity labels. For sensitivity label licensing information, see Microsoft 365 licensing guidance for security & compliance.

Task 6: Configure a retention policy

A retention policy lets you proactively decide whether to retain content, delete content, or both—retain and then delete the content at the end of a specified retention period. These actions might be needed to comply with industry regulations and internal policies, as well as reduce your risk in the event of litigation or a security breach.

When content is subject to a retention policy, people can continue to edit and work with the content as if nothing's changed. The content is retained in place, in its original location. But if someone edits or deletes content that's subject to the retention policy, a copy of the original content is saved to a secure location where it's retained while the retention policy for that content is in effect.

You can quickly put a retention policy in place for multiple locations in your Microsoft 365 environment such as Exchange mail, SharePoint sites, OneDrive accounts, and Microsoft 365 groups. There are no limits to the number of mailboxes or sites this policy can automatically include. But if you need to get more selective, you can do so by configuring a retention policy for specific locations and include or exclude sites or users.

For step-by-step guidance to configure a retention policy, see Create and configure retention policies. If you're new to configuring retention in Microsoft 365, see Get started with retention policies and retention labels.

Task 7: Configure sensitive information and offensive language policies

Protecting sensitive information and detecting and acting on workplace harassment incidents is an important part of compliance with internal policies and standards. Communication compliance in Microsoft 365 helps minimize these risks by helping you quickly detect, capture, and take remediation actions for email and Microsoft Teams communications. These include inappropriate communications containing profanity, threats, and harassment and communications that share sensitive information inside and outside of your organization.

A pre-defined *Offensive language and anti-harassment* policy template allows you to scan internal and external communications for policy matches so they can be examined by designated reviewers. Reviewers can investigate scanned email, Microsoft Teams, Yammer, or third-party communications in your organization and take appropriate remediation actions to make sure they're compliant with your organization's standards.

The pre-defined *Sensitive information* policy template helps you quickly create a policy to scan email and Microsoft Teams communications containing defined sensitive information types or keywords to help make sure that important data isn't shared with people that shouldn't have access. These activities could include unauthorized communication about confidential projects or industry-specific rules on insider trading or other collusion activities.

For step-by-step guidance to plan and configure communication compliance, see Plan for communication compliance and Get started with communication compliance. For communication compliance licensing information, see Microsoft 365 licensing guidance for security & compliance.

Task 8: See what's happening with your sensitive items

Sensitivity labels, sensitive information types, retention labels and policies and trainable classifiers can be used to classify and label sensitive items across Exchange, SharePoint, and OneDrive as you've seen in the previous tasks. The last step in your quick task journey is to see which items have been labeled and what actions your users are taking on those sensitive items. content explorer and activity explorer provide this visibility.

Content explorer

Content explorer allows you to view, in their native format, all the items that have been classified as a sensitive information type or belonging to a certain classification by a trainable classifier, as well as all items that have sensitivity or retention label applied.

For step-by-step guidance to using content explorer, see Know your data - data classification overview, and Get started with content explorer.

Activity explorer

Activity explorer helps you monitor what's being done with your classified and labeled sensitive items across:

- SharePoint
- Exchange
- OneDrive

There are over 30 different filters available for use, some are:

- date range
- activity type
- location
- user
- sensitivity label
- retention label
- file path
- DLP policy

For step-by-step guidance to using activity explorer, see Get started with activity explorer.

Next steps

Now that you've configured the basics for compliance management for your organization, consider the following compliance solutions in Microsoft 365 to help you protect sensitive information and detect and act on additional insider risks.

Configure retention labels

While retention policies apply at the container level to locations such as SharePoint sites and Exchange mailboxes, retention labels allow for more specific targeting for your retention and deletion policies. For example, at the document or email message level that end users can apply manually in addition to automatic application by administrators. You can also apply a retention label to a document library, folder, or document set in SharePoint, so that all documents that are stored in that location inherit the default retention label.

Additionally, retention labels support records management to mark content as a record. When this happens, the label places additional restrictions on the content that might be needed to help your organization comply with regulatory requirements.

For step-by-step guidance to create and publish retention labels, see the following guidance:

- Create retention labels and apply them in apps
- Apply a retention label to content automatically

To get started with records management, see Get started with records management.

Identify and define sensitive information types

Define sensitive information types based on the pattern contained in information in your organization's data. Use built-in sensitive information types help identify and protect credit card numbers, bank account numbers, passport numbers, and more. Or create your own custom sensitivity information types specific to your organization.

For step-by-step guidance to define custom sensitive information types, see Create a custom sensitive information type in the Security & Compliance Center.

Prevent data loss

Data loss prevention (DLP) policies allow you to identify, monitor, and automatically protect sensitive information across your Microsoft 365 organization. Use DLP policies to identify sensitive items across Microsoft services, prevent the accidental sharing of sensitive items, and help users learn how to stay compliant without interrupting their workflow.

For step-by-step guidance to configure DLP policies, Create, test, and tune a DLP policy. For data loss management licensing information, see Microsoft 365 licensing guidance for security & compliance.

Detect and act on insider risks

More and more, employees have increasing access to create, manage, and share data across a broad spectrum of platforms and services. In most cases, organizations have limited resources and tools to identify and mitigate organization-wide risks while also meeting compliance requirements and employee privacy standards. These risks may include data theft by departing employees and data leaks of information outside your organization by accidental oversharing or malicious intent.

Insider risk management in Microsoft 365 uses the full breadth of service and 3rd-party indicators to help you quickly identify, triage, and act on risky user activity. By using logs from Microsoft 365 and Microsoft Graph, insider risk management allows you to define specific policies to identify risk indicators and to take action to mitigate these risks.

For step-by-step guidance to plan and configure insider risk management policies, see Plan for insider risk management and Get started with insider risk management. For insider risk management licensing information, see Microsoft 365 licensing guidance for security & compliance.

What's new in Microsoft 365 compliance

2/18/2021 • 12 minutes to read • Edit Online

Whether it be adding new solutions to the Microsoft 365 compliance center, updating existing features based on your feedback, or rolling out fresh and updated documentation, Microsoft 365 helps you stay on top of the ever-changing compliance landscape. Take a look below to see what's new in Microsoft 365 compliance today.

> **NOTE**
>
> Some compliance features get rolled out at different speeds to our customers. If you aren't seeing a feature yet, try adding yourself to targeted release.

> **TIP**
>
> Interested in what's going on in other admin centers? Check out these articles:
> What's new in the Microsoft 365 admin center
> What's new in the SharePoint admin center
> What's new in Microsoft 365 Defender
>
> And visit the Microsoft 365 Roadmap to learn about Microsoft 365 features that were launched, are rolling out, are in development, have been cancelled, or previously released.

January 2021

Support for card content in Teams

The following Microsoft 365 compliance solutions now support the detection of card content generated through apps in Teams messages:

- **Core and Advanced eDiscovery**. Card content can now be placed on hold or included in searches (applies to content search as well).
- **Audit**. Card activity is now recorded to the audit log.
- **Retention policies**. Can now use retention policies to retain and delete card content.

Information governance and records management

New assessment to address using information governance and records management to help meet compliance obligations for the New Zealand Public Records Act.

Sensitivity labels

- Sensitivity labels are now supported for US Government tenants (GCC and GCC-H).
- New automatic labeling support for macOS.

December 2020

Spotlight: New content for insider risk solutions

The Microsoft 365 compliance content team is hard at work creating 'content solution' docs to promote how compliance capabilities can be used together to help meet your compliance goals.

First up is content that ties together our insider risk solutions: communication compliance, insider risk management, information barriers, and privileged access management. Here's a peek at what you'll find:

- New landing page for insider risk solutions. Includes details about risks that the solutions can help mitigate, licensing requirements, deployment sequence, architecture illustrations, training resources, and more.
- New overview articles for each insider risk solution. Guidance and links to articles that help you learn about, plan, deploy, and manage each solution:
  - Communication compliance
  - Insider risk management
  - Information barriers
  - Privileged access management

More content solution docs coming soon!

Advanced eDiscovery

Improved workflow and functionality for adding custodians and non-custodial data sources to an Advanced eDiscovery case.

Data connectors

Four new Globanet connectors released: Redtail Speak, Salesforce Chatter, ServiceNow, and Yieldbroker.

Encryption

Introducing Customer Key for Microsoft 365 at the tenant level. Using keys you provide, you can create a data encryption policy (DEP) and assign it to the tenant. The DEP encrypts data across the tenant for these workloads:

- Teams chat messages (1:1 chats, group chats, meeting chats and channel conversations)
- Teams media messages (images, code snippets, videos, wiki images)
- Teams call and meeting recordings stored in Teams storage
- Teams chat notifications
- Teams chat suggestions by Cortana
- Teams status messages
- User and signal information for Exchange Online

Records management

The Records Management admin role group now grants permissions for all records management features, including disposition review.

Sensitivity labels

- Automatically label data in Azure Purview (preview). You can now create and automatically apply sensitivity labels to assets in Azure Purview, such as files in Azure Blob storage and database columns in SQL Server.
- Require users to apply a label to items. Also known as 'mandatory labeling', this new option requires users to choose and apply a sensitivity label under the specific scenarios.

November 2020

Just a reminder that we often release new and updated features in a preview state to learn how they're being used so we can hone and improve them before releasing to general availability. Your feedback is critical during preview (and beyond), so be sure to let us know what you think by opening the Feedback card at the bottom right of the compliance center.

Spotlight: Endpoint data loss prevention (DLP) released

Endpoint DLP extends the activity monitoring and protection capabilities of DLP to sensitive info on Windows 10 devices. After devices are onboarded to the Microsoft 365 compliance center, you can set up DLP policies to

protect the sensitive info on those devices.

Advanced eDiscovery

To make it easier to manage encrypted content in the eDiscovery workflow, Microsoft 365 eDiscovery tools now incorporate decryption of encrypted files that are attached to email messages and sent in Exchange. Additionally, encrypted documents stored in SharePoint and OneDrive are decrypted in Advanced eDiscovery.

Compliance Manager

- Support for Microsoft 365 Government subscriptions. Compliance Manager is now available to US Government Community (GCC) Moderate and High customers.
- Microsoft Compliance Configuration Analyzer for Compliance Manager. New PowerShell-based tool that helps you get started with Compliance Manager by scanning your organization's current configurations and validating them against Microsoft 365 recommended best practices.
- New templates. Added 56 new templates, bringing total Compliance Manager templates to over 230.

Data connectors

Five new Globanet connectors in preview. New connectors include Reuters Dealing, Reuters FX, CellTrust, XIP, generic MS SQL Database data.

Retention labels (disposition review)

To view items during a disposition review, users must now be members of the Content Explorer Content Viewer and Content Explorer List Viewer role groups. Although required to review items, these role groups aren't necessary for completing the disposition review.

Sensitivity labels

- (Preview) External sharing settings for SharePoint sites. When creating a label that will be used for groups and sites, you'll see an option to control external sharing for SharePoint sites that have the label applied. You can specify that sharing is allowed for anyone, new and existing guests, existing guests only, or just users in your organization. When the label is applied, the label settings will replace any external sharing settings configured in the SharePoint admin center.
- Remove label and encryption from a labeled document. To remove both a label and the encryption it enforces from a labeled document in SharePoint, global admins and SharePoint admins can run the new `Unlock-SPOSensitivityLabelEncryptedFile` cmdlet. This cmdlet runs even if the admin doesn't have access permissions to the site or file, or if the Azure Rights Management service is unavailable.

October 2020

Advanced eDiscovery

CJK language support. Advanced eDiscovery now supports double-byte character set languages, collectively known as CJK languages (includes Simplified Chinese, Traditional Chinese, Japanese, and Korean). These can be used in several advanced review set scenarios.

Sensitivity labels

- Label scope. When creating a sensitivity label, you'll see a new option to define the scope for the label. This option lets you configure labels just for files and emails, containers (like SharePoint sites and Teams), or both.
- Dynamic content marking. When configuring content marking for a sensitivity label, you can now use the dynamic variables such as `${Item.Label}` and `${Item.Location}` in the text string for your header, footer, or watermark.

September 2020

Spotlight: Compliance Manager

Announced at Ignite this year, Compliance Score is rebranded as Compliance Manager. This release completes

the transition from Compliance Manager's previous home in the Service Trust Portal, and introduces an end-to-end compliance management solution in the Microsoft 365 compliance center.

Watch the video below to learn how Compliance Manager can help simplify how your organization manages compliance.

Advanced Audit

- New 10-year retention of audit logs helps support long running investigations and respond to regulatory, legal, and internal obligations.
- Three new crucial events. The following new events can help you investigate possible breaches and determine the scope of compromise: Send, SearchQueryInitiatedExchange, and SearchQueryInitiatedSharePoint.

Communication compliance

- Updated role groups. Communication compliance role groups now match the role group structure available for the insider risk management solution.
- Reports dashboard. Your central location for viewing all communication compliance reports. Report widgets provide a quick view of insights most commonly needed for an overall assessment of the status of communication compliance activities.
- Power Automate flows. Set up flows to automate tasks for alerts and users, notify managers when users trigger an alerts, and more.
- 'Improve classification' remediation action. Alerts containing items that match trainable classifiers might benefit from feedback to help minimize false positives in your organization. The **Improve classification** option lets you provide feedback whether detected items match the classifier configured in the related communication compliance policy. You can even suggest other classifiers to associate with the item to improve match accuracy for future alerts.

Data connectors

- New third-party data connectors. 25 new data connectors, including 14 connectors from Globanet and 8 from Telemessage.
- Physical badging connector. Import physical badging data, such as employee's raw physical access events or any physical access alarms generated by your organization's badging system. Examples include entries to buildings, server rooms, or data centers. Physical badging data can be used by the insider risk management solution to help protect your organization from malicious activity or data theft inside your organization.

Insider risk management

- Microsoft Teams integration. When Teams integration is turned on in insider risk settings, you can coordinate and collaborate with other stakeholders in Teams on tasks like securely sharing and storing data related to individual cases, tracking and reviewing response activities from analysts and investigators, and more.
- Power Automate flows. Set up flows to automate important tasks for cases and users, such as retrieving user, alert, and case info to share with stakeholders and other apps, automating actions like posting to case notes, and more.
- Activity explorer. Available when reviewing alerts, activity explorer provides investigators and analysts with a comprehensive analytic tool for drilling down into each alert. Quickly review a timeline of detected risky activity and identify and filter all risk activities associated with alerts.

Retention policies and retention labels

- Support for Yammer. You can now use retention policies to retain and delete Yammer community messages and private messages.
- Apply labels to Teams meetings recordings. When creating an auto-labeling policy, use the keyword query

editor to identify Teams meeting recordings that are stored in users' OneDrive accounts or in SharePoint.

Records management

Support for regulatory records. Classifying a label as a regulatory record increases the restrictions placed on content to which the label is applied and limits the available management actions for the label itself. For example, after it's applied to content, nobody, not even a global admin, can remove the label. Learn more about which actions are allowed and blocked for regulatory records.

Sensitivity labels

Support for US Government customers. Sensitivity labels are now supported for GCC, GCC High, and DoD customers, only for the Azure Information Protection unified labeling client and scanner.

Trainable classifiers

New retraining and feedback capabilities helps improve accuracy and minimize false positive matches for all custom classifiers and some pre-trained classifiers. This flow lets you provide feedback on whether items match certain classifiers, suggest other classifiers to associate with items, and retrain classifiers to refine and improve match accuracy.

This new capability is included in the following features:

> **NOTE**
> For all features, if you provide at least 30 feedback responses, we'll create a retrained version of that classifier that you can review. If there's improvement, you can republish the classifier.

- Trainable classifiers. To improve the accuracy of your published classifiers, you can provide feedback on whether the detected items match the classifier.
- Communication compliance. The new **Improve classification** remediation action lets you provide feedback whether an item from a communication compliance alert matches the classifier configured in the communication compliance policy.
- Content explorer. If you set up a retention auto-labeling policy to automatically apply labels to email messages that match trainable classifiers, you can use content explorer to review the labeled items and provide feedback whether the items match the classifier.

August 2020

Spotlight: Insider risk and communication compliance updates

Several new and improved features hit public preview this month:

Insider risk management

- Check out our six new policy templates:
  - Data leaks by priority users
  - Data leaks by disgruntled users
  - General security policy violations
  - Security policy violations by departing users
  - Security policy violations by priority users
  - Security policy violations by disgruntled users
- Integration with Microsoft Defender for Endpoint allows you to import and filter Microsoft Defender for Endpoint alerts for activities detected by policies created from the new security violation policy templates. There's also a related insider risk setting where you can choose to import security alerts to insider risk management based on the Microsoft Defender for Endpoint alert triage status.

> **NOTE**
>
> To take advantage of Microsoft Defender for Endpoint integration (including the new security policy violation templates), you'll need to have Microsoft Defender for Endpoint configured in your organization. You'll also need to enable Microsoft Defender for Endpoint for insider risk management integration by configuring advanced features in Microsoft Defender for Endpoint.

- Customize indicator thresholds when creating a policy.
- Set up priority user groups to define users in your organization whose activity requires closer inspection based on factors such as their position, level of access to sensitive information, or risk history.
- Use Office 365 Management Activity APIs to export insider risk alert details to other applications your organization might use to manage or aggregate insider risk data.
- New domain settings help you define and control risk levels for activity in specific domains.

Communication compliance

- When reviewing messages in an alert, you can now remove inappropriate messages in Microsoft Teams channels, 1:1, and group chats. Removed messages and content are replaced with a policy tip that explains that it was removed due to sensitive content.
- New communication roles (these will also be included in new communication compliance role groups releasing in September).
- New communication compliance settings experience that includes settings for privacy and notice templates.
- New classifiers to help detect adult, racy, and gory images.
- New 'Pattern detected' notification that appears when reviewing messages in an alert lets you know about reoccurring instances of the same behavior by a user.

Sensitivity labels

- For US Government tenants (GCC, GCC-H, and DoD), sensitivity labels are currently supported only for the Azure Information Protection unified labeling client and scanner. For more information, see Azure Information Protection Premium Government Service Description.
- You can now use Security & Compliance Center PowerShell to create and configure all settings you see in your labeling admin center. This means that, in addition to using PowerShell for settings that aren't available in the labeling admin centers, you can now fully script the creation and maintenance of sensitivity labels and sensitivity label policies.

Records management: Content overhaul

New docs covering deployment steps, marking content as records, and record versioning:

- Get started with records management
- Declare records by using retention labels
- Use record versioning to update records stored in SharePoint or OneDrive

Retention labels & policies

Retention-related admin activity is now recorded and available to review in the audit log. For the full list, see Retention policy and retention label activities.

Advanced eDiscovery

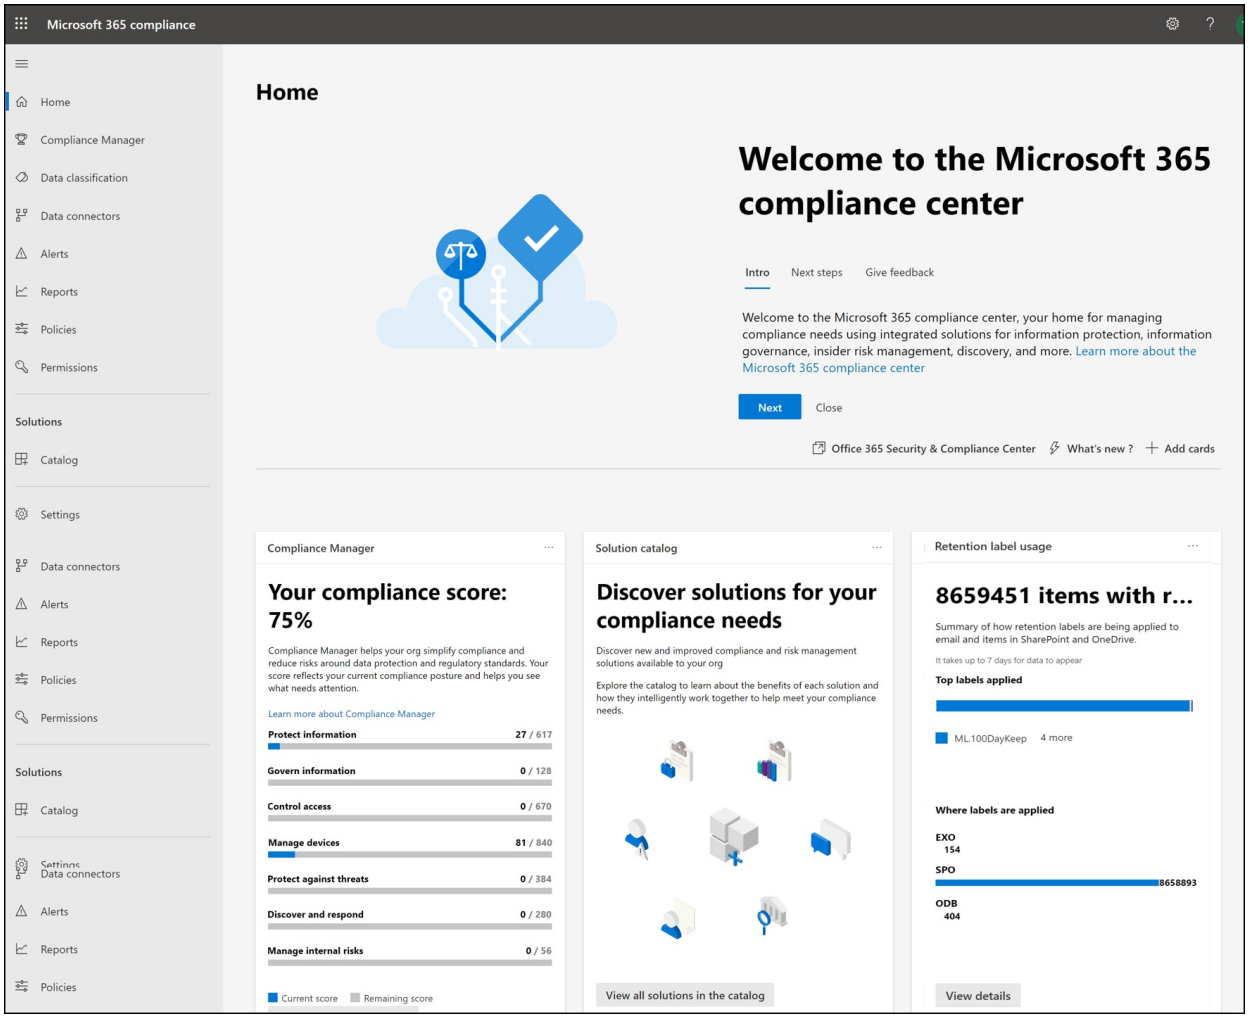
- When adding a collection to a review set, you can now include modern attachments (also called "cloud attachments") and SharePoint document versions.
- New direct download export experience, eliminating the need to use Azure Storage Explorer to download case content.

Microsoft 365 compliance center

2/18/2021 • 6 minutes to read • Edit Online

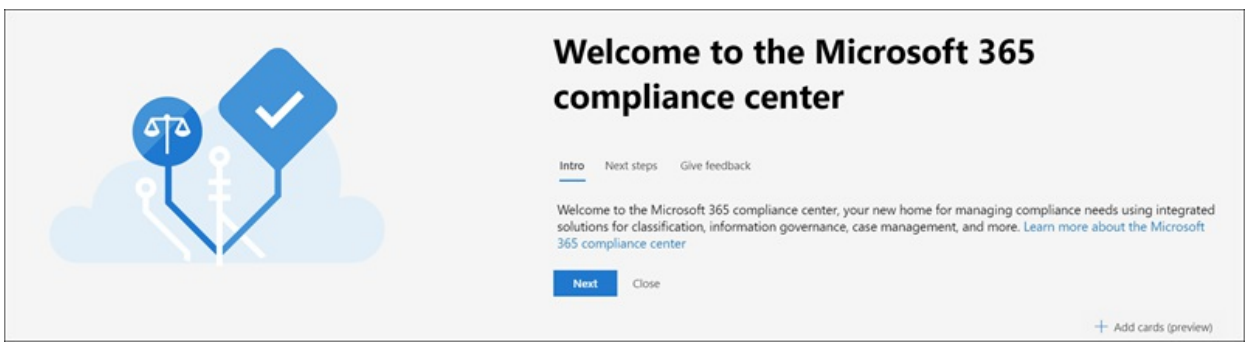
If you're interested in your organization's compliance posture, you're going to love the Microsoft 365 compliance center. The Microsoft 365 compliance center provides easy access to the data and tools you need to manage to your organization's compliance needs.

Read this article to get acquainted with the Microsoft 365 compliance center, how to get it, frequently asked questions, and your next steps.



Welcome to Microsoft 365 compliance

When you go to your Microsoft 365 compliance center for the first time, you're greeted with the following welcome message:



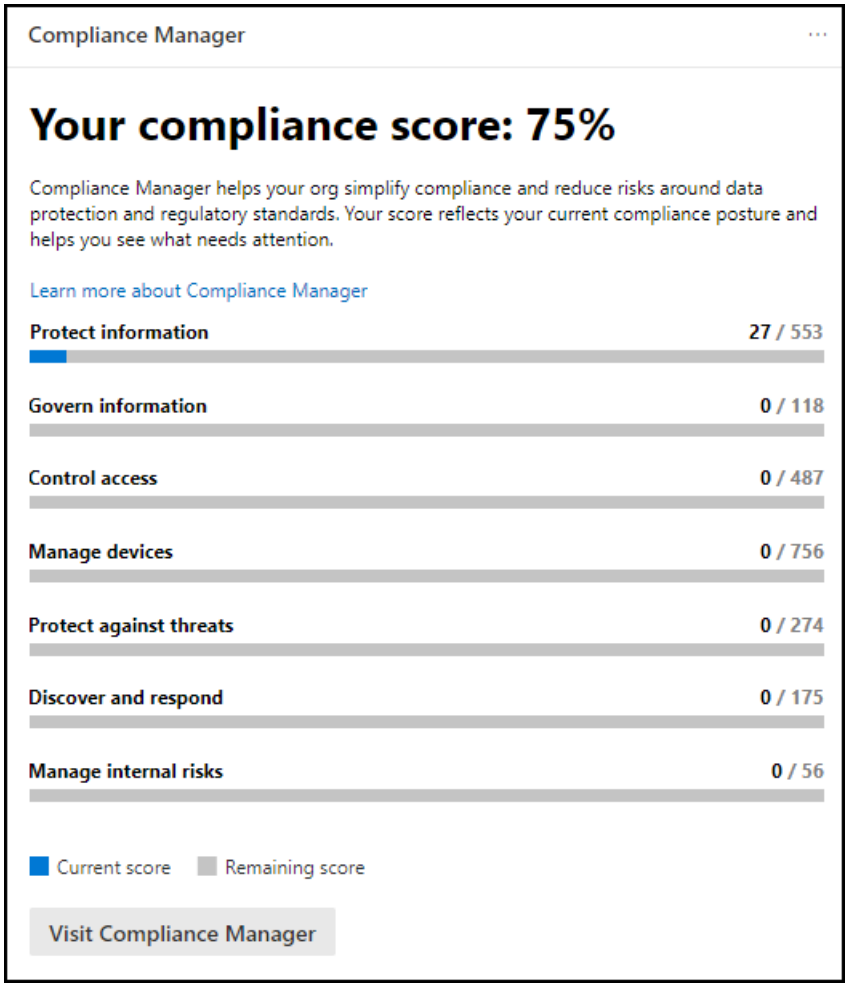
The welcome banner gives you some pointers on how to get started, with next steps, and an invitation for you to give us feedback.

Card section

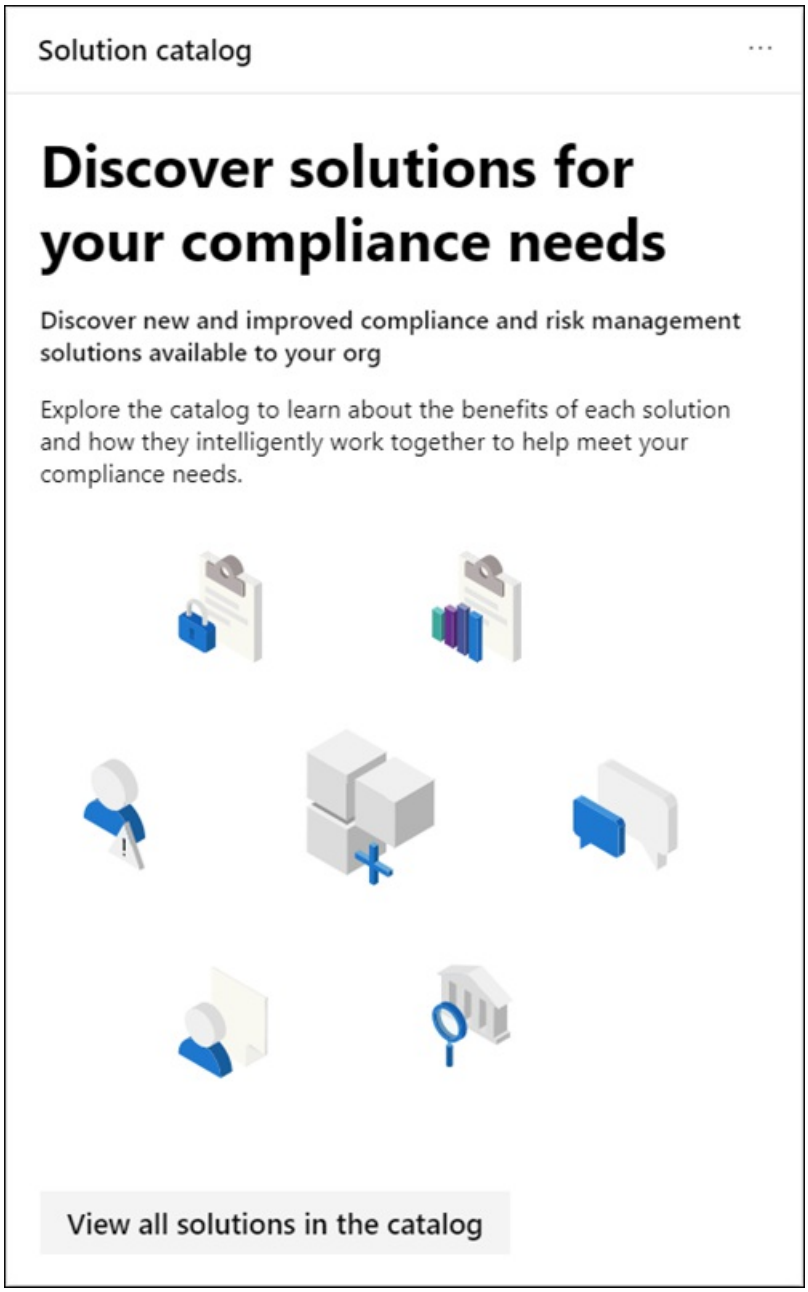
When you first visit the Microsoft 365 compliance center, the card section on the home page shows you at a glance how your organization is doing with data compliance, what solutions are available for your organization, and a summary of any active alerts.

From here, you can:

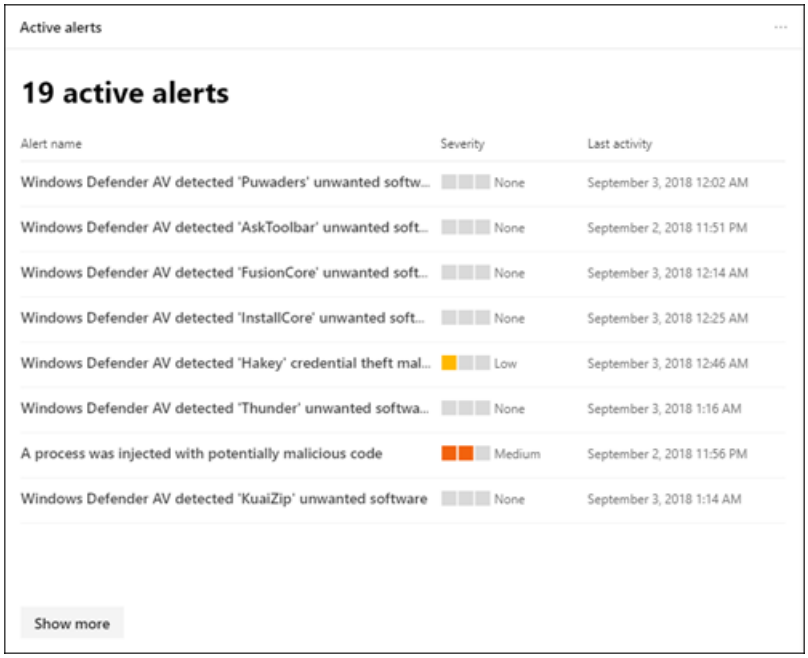
- Review the **Microsoft Compliance Manager** card, which leads you to the Compliance Manager solution. Compliance Manager helps simplify the way you manage compliance. It calculates a risk-based score measuring your progress toward completing recommended actions that help reduce risks around data protection and regulatory standards. It also provides workflow capabilities and built-in control mapping to help you efficiently carry out improvement actions.



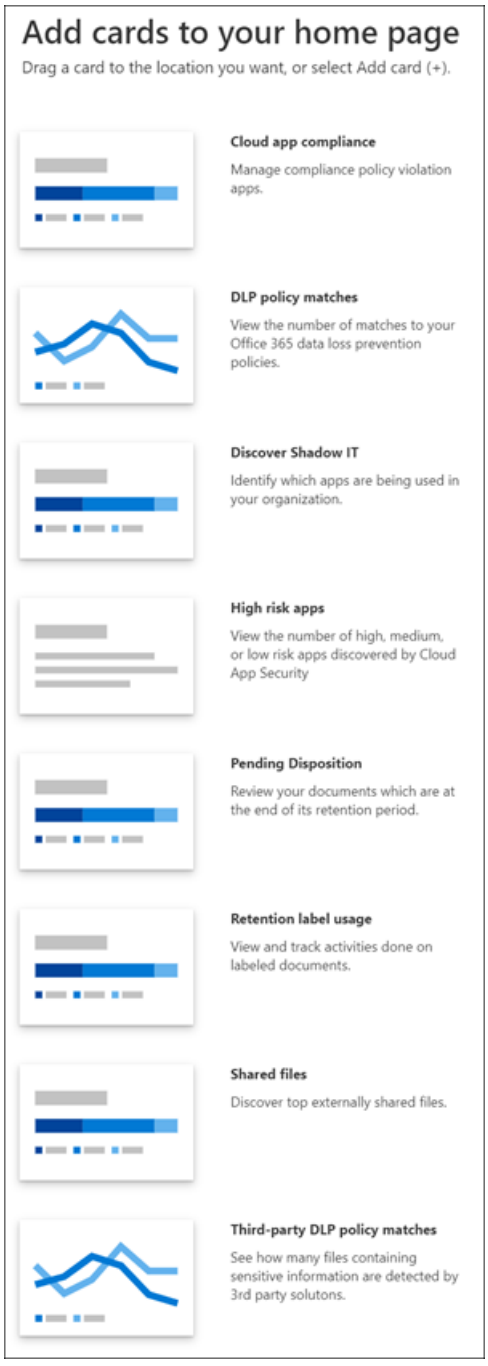
- Review the new **Solution catalog** card, which links to collections of integrated solutions you can use to help you manage end-to-end compliance scenarios. A solution's capabilities and tools might include a combination of policies, alerts, reports, and more.



- Review the **Active alerts** card, which includes a summary of the most active alerts and includes a link where you can view more detailed information, such as Severity, Status, Category, and more.



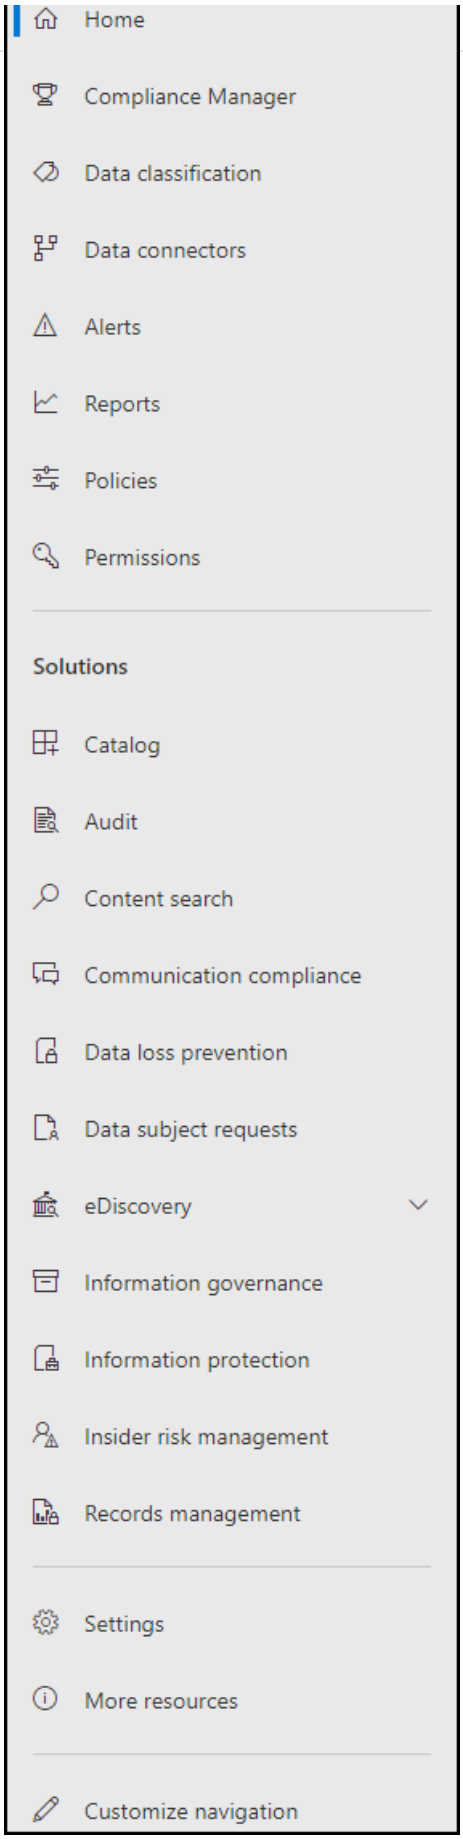
You can also use the **Add cards** feature to add additional cards, such as one showing your organization's cloud app compliance, and another showing data about users with shared files, with links to Cloud App Security or other tools where you can explore data.



Easy navigation to more compliance features and capabilities

In addition to links in cards on the home page, you'll see a navigation pane on the left side of the screen that gives you easy access to your alerts, reports, policies, compliance solutions, and more. To add or remove options for a customized navigation pane, use the **Customize navigation** control on the navigation pane. This opens the **Customize your navigation pane** settings so you can configure which items appear in the navigation pane.

	Select **Home** to return to the Microsoft 365 compliance center main page. Visit **Compliance Manager** to check your compliance score and start managing compliance for your organization.



Select the **Data classification** section to access trainable classifiers, Sensitive information type entity definitions, content and activity explorers.

Select **Data connectors** to configure connectors to import and archive data in your Microsoft 365 subscription.

Go to **Alerts** to view and resolve alerts

Visit **Reports** to view data about label usage and retention, DLP policy matches and overrides, shared files, third-party apps in use, and more.

Go to **Policies** to set up policies to govern data, manage devices, and receive alerts. You can also access your DLP and retention policies.

Select **Permissions** to manage who in your organization has access to the Microsoft 365 compliance center to view content and complete tasks.

Use the links in the **Solutions** section to access your organization's compliance solutions. These include:

Catalog
Discover, learn about, and start using the intelligent compliance and risk management solutions available to your organization.

Audit
Use the Audit log to investigate common support and compliance issues.

Content search
Use Content search to quickly find email in Exchange mailboxes, documents in SharePoint sites and OneDrive locations, and instant messaging conversations in Microsoft Teams and Skype for Business.

Communication compliance
Minimize communication risks by automatically capturing inappropriate messages, investigating possible policy violations, and taking steps to remediate.

Data loss prevention
Detect sensitive content as it's used and shared throughout your organization, in the cloud and on devices, and helps prevent accidental data loss.

Data subject requests
Find and export a user's personal data to help you respond to data subject requests for the General Data Protection Regulation (GDPR).

eDiscovery
Expand this section to use the core and Advanced eDiscovery for preserving, collecting, reviewing, analyzing, and exporting content that's responsive to your organization's internal and external investigations.

Information governance
Manage your content lifecycle using features to import, store, and classify business-critical data so you can keep what you need and delete what you don't.

	Information protection Discover, classify, and protect sensitive and business-critical content throughout its lifecycle across your organization. Insider risk management Detect risky activity across your organization to help you quickly identify, investigate, and take action on insider risks and threats. Records management Automate and simplify the retention schedule for regulatory, legal and business-critical records in your organization.

How do I get the compliance center?

- If you don't have the new Microsoft 365 compliance center already, you'll have it soon. The Microsoft 365 compliance center is generally available now to Microsoft 365 SKU customers.
- To visit the Microsoft 365 compliance center, as a global administrator, compliance administrator, or compliance data administrator go to https://compliance.microsoft.com and sign in.

Frequently asked questions

Why am I taken to the Security & Compliance Center to complete some tasks, such as defining certain policies?

We're still developing the Microsoft 365 compliance center, and we add more functionality and solutions over the coming months. In the meantime, there are a few tasks that must be completed in the Security & Compliance Center (https://protection.office.com). In those cases, you'll be directed automatically to the location where you can complete the task at hand, such as creating or editing a supervision policy.

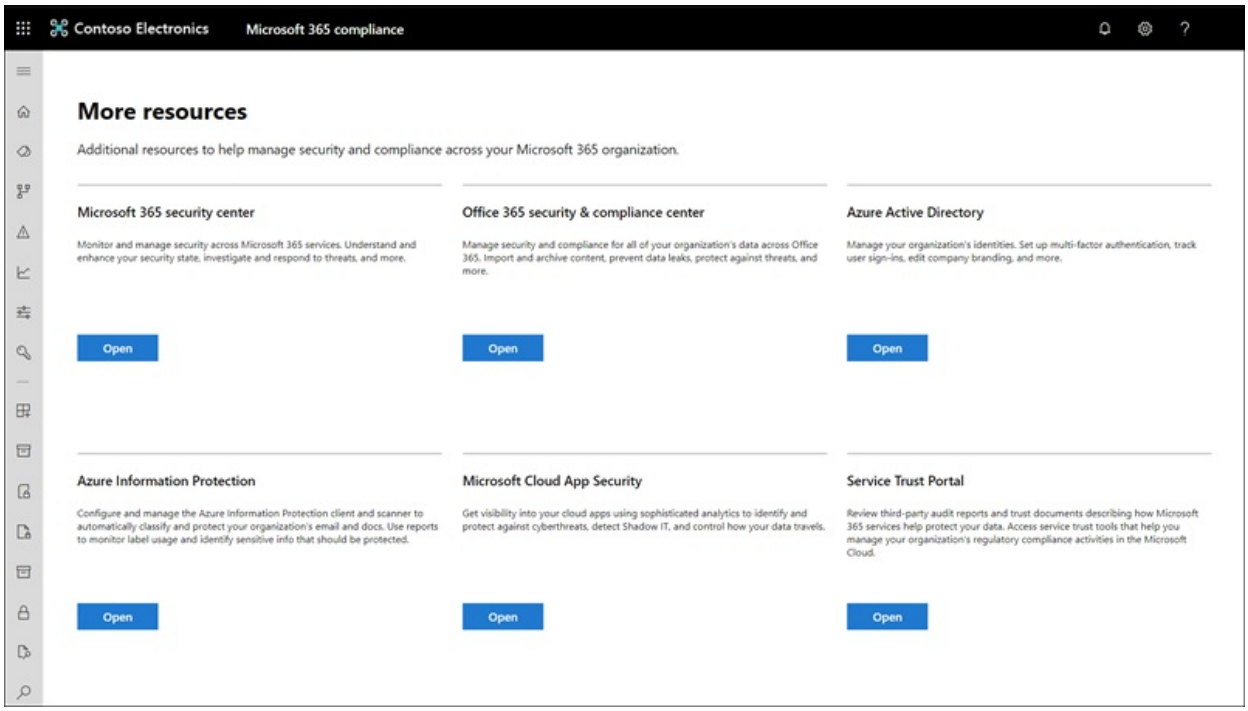
Why don't I see the new Microsoft 365 compliance center yet?

First, make sure that you have the appropriate licenses and permissions. Then, sign in at https://compliance.microsoft.com. If you don't see the new compliance center yet, you'll have it soon.

Some of my compliance features aren't available in the Microsoft 365 compliance center. What do I do?

We're still adding functionality to the Microsoft 365 compliance center. If you can't find something, such as audit log search, use the Security & Compliance Center (https://protection.office.com). Your configurations are saved in both the existing Security & Compliance Center and in the new Microsoft 365 compliance center automatically.

To go there, in the Microsoft 365 compliance center, in the navigation pane on the left side of the screen, choose **More resources**, and then, under **Office 365 Security & Compliance Center**, choose **Open**.



Next steps

- **Visit Microsoft Compliance Manager** to see your compliance score and start managing compliance for your organization. To learn more, see Compliance Manager.
- **Configure insider risk management policies** to help minimize internal risks and enable you to detect, investigate, and take action for risky activities in your organization. See Insider risk management.
- **Review your organization's data loss prevention policies** and make required changes as necessary. To learn more about, see Overview of data loss prevention policies.
- **Get acquainted with and set up Microsoft Cloud App Security**. See Quickstart: Get started with Microsoft Cloud App Security.
- **Learn about and create communication compliance policies** to quickly identify and remediate corporate code-of-conduct policy violations. See Communication compliance in Microsoft 365.
- **Visit your Microsoft 365 compliance center often**, and make sure to review any alerts or potential risks that arise. Go to https://compliance.microsoft.com and sign in.

Microsoft 365 solution catalog

2/18/2021 • 4 minutes to read • Edit Online

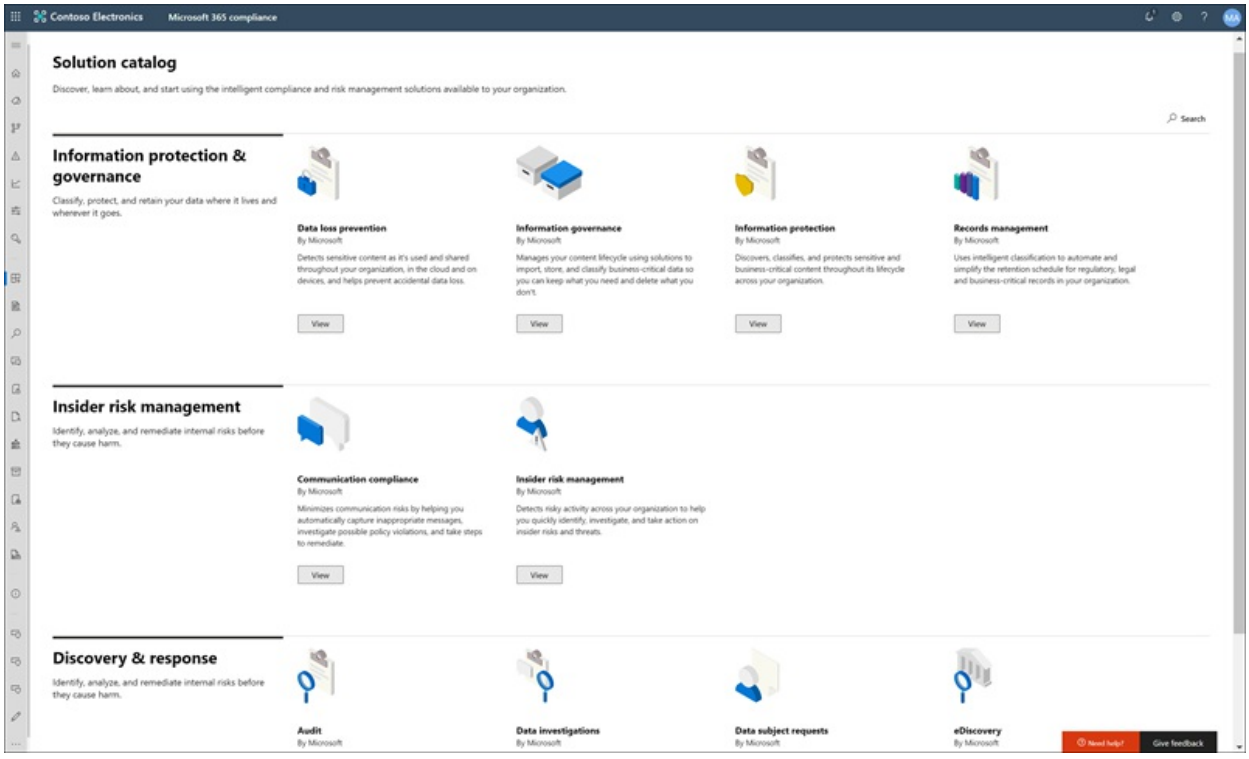
Are you looking for a way to quickly get started with compliance tasks in Microsoft 365? Check out the Microsoft 365 solution catalog to discover, learn, and quickly get started with compliance and risk management solutions.

Compliance solutions in Microsoft 365 are collections of integrated capabilities you can use to help you manage end-to-end compliance scenarios. A solution's capabilities and tools might include a combination of policies, alerts, reports, and more.

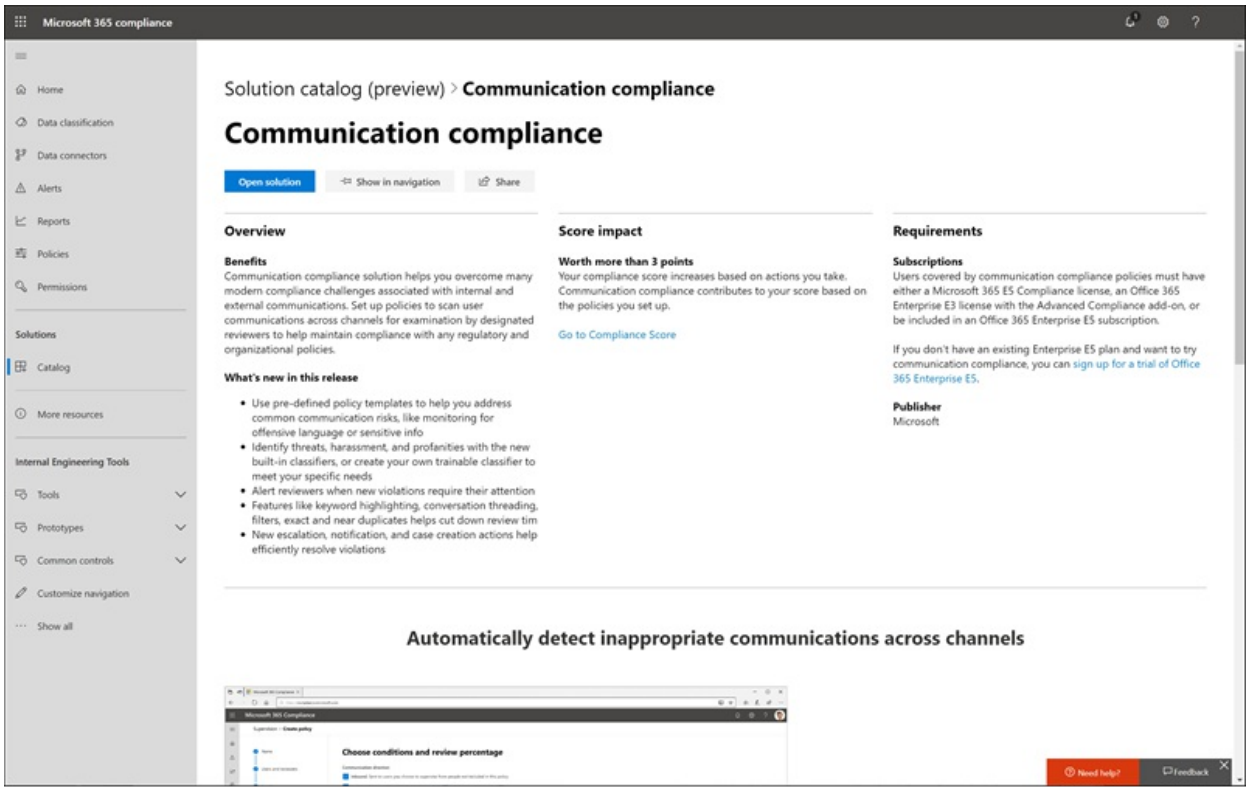
Read this article to get acquainted with the new solution catalog in the Microsoft 365 compliance center, how to get it, frequently asked questions, and your next steps.

Catalog organization

The solution catalog is organized into sections that contain information cards for each compliance solution available in your Microsoft 365 subscription. Each section contains cards for solutions grouped by compliance area.

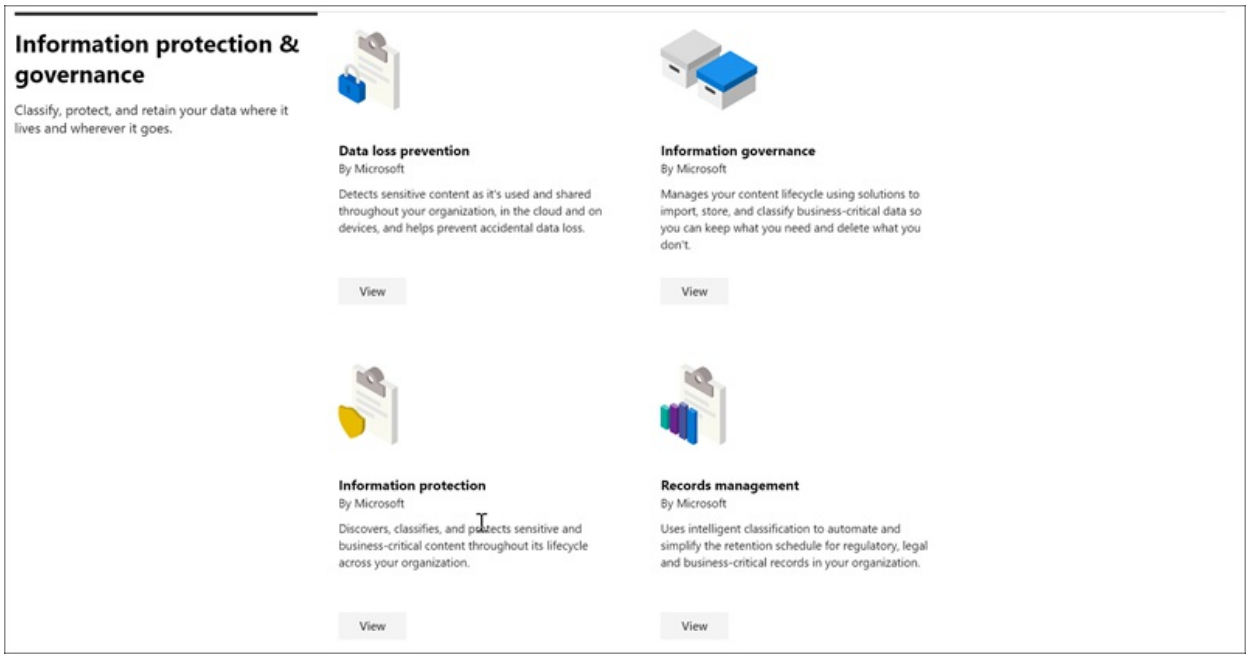


When you select **View** for a solution card, you'll see detailed information about the compliance solution and how to get started. This information includes an overview, pre-configuration requirements, learning resources, controls that allow you to pin the card to the navigation pane, and an option to share the solution as a link, email, or Microsoft Teams message.



Information protection & governance section

The **Information protection & governance** section shows you at a glance how you can use Microsoft 365 compliance solutions to protect and govern data in your organization.

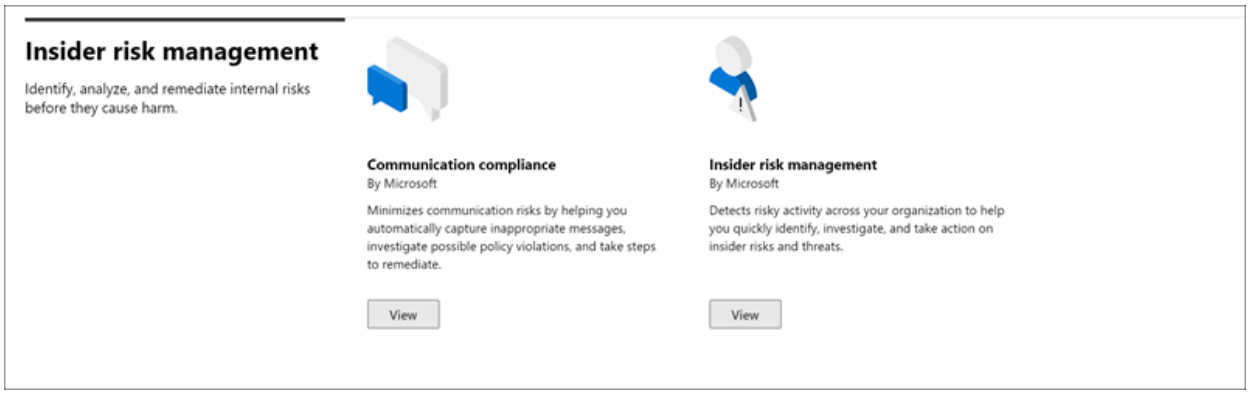


From here, you'll see cards for the following solutions:

- Data loss prevention: Detects sensitive content as it's used and shared throughout your organization, in the cloud and on devices, and helps prevent accidental data loss.
- Information governance: Manages your content lifecycle using solutions to import, store, and classify business-critical data so you can keep what you need and delete what you don't.
- Information protection: Discovers, classifies, and protects sensitive and business-critical content throughout its lifecycle across your organization.
- Records management: Uses intelligent classification to automate and simplify the retention schedule for regulatory, legal, and business-critical records in your organization.

Insider risk management section

The **Insider risk management** section on the home page shows you at a glance how your organization can identify, analyze, and take action on internal risks before they cause harm.

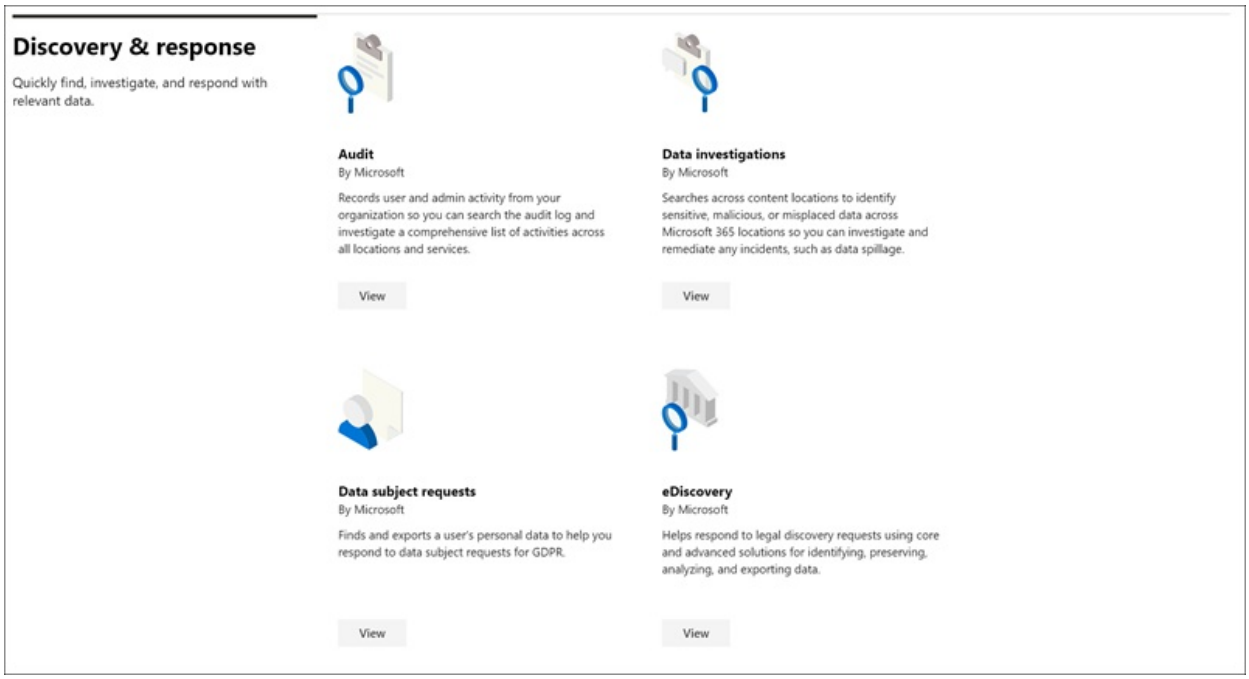


From here, you'll see cards for the following solutions:

- Communication compliance: Minimizes communication risks by helping you automatically capture inappropriate messages, investigate possible policy violations, and take steps to minimize harm.
- Insider risk management: Detect risky activity across your organization to help you quickly identify, investigate, and take action on insider risks and threats.

Discovery & response section

The **Discovery & response** section on the home page shows you at a glance how your organization can quickly find, investigate, and respond to compliance issues with relevant data.



From here, you'll see cards for the following solutions:

- Audit: Records user and admin activity from your organization so you can search the audit log and investigate a comprehensive list of activities across all locations and services.
- Data subject requests: Finds and exports a user's personal data to help you respond to data subject requests for GDPR.
- eDiscovery
  - Core eDiscovery: Searches across content locations to identify, preserve, and export data in response to legal discovery requests and eDiscovery cases.

- Advanced eDiscovery: Builds on eDiscovery capabilities by providing intelligent analytics and machine learning to help you further analyze data that's relevant to discovery requests.

How do I get this?

To visit the Microsoft 365 solution catalog, go to https://compliance.microsoft.com and sign in as a global administrator, compliance administrator, or compliance data administrator. Select **Catalog** in the navigation pane on the left side of the screen to open the catalog home page.

Frequently asked questions

Why don't I see the Microsoft 365 solution catalog?

First, make sure that you have the appropriate licenses and permissions. Then, sign in at https://compliance.microsoft.com as a global administrator, compliance administrator, or compliance data administrator.

Some of the compliance features listed on the solution catalog page aren't available in the Microsoft 365 compliance center. What do I do?

We're always working to add new functionality to the Microsoft 365 compliance center and the solution catalog. If you can't find a specific solution in the navigation area, it will be accessible when the solution is available in your subscription.

If you are looking for an existing compliance solution and it's not available in the Microsoft 365 compliance center yet, you can always access solutions in the existing Security & Compliance Center by going to https://protection.office.com. Alternatively, you can click on the **More resources** tab in the left navigation of the Microsoft 365 compliance center and select the Office 365 security and compliance center card.

Next steps

- **Visit Microsoft Compliance Manager**, which helps you understand your organization's state of compliance with key standards and regulations. It provides recommended actions you can take to strengthen your overall compliance posture, and provides workflow capabilities to help you efficiently carry out those actions. To learn more, see Compliance Manager.
- **Configure insider risk management policies** to help minimize internal risks and enable you to detect, investigate, and take action for risky activities in your organization. See Insider risk management.
- **Learn about and create Communication compliance policies** to quickly identify and remediate corporate code-of-conduct policy violations. See Communication compliance.
- **Microsoft Information Protection**, learn how Microsoft 365 solutions help you discover, classify, and protect sensitive information wherever it lives or travels.
  - **Get acquainted with and set up Microsoft Cloud App Security**. See Quickstart: Get started with Microsoft Cloud App Security.
  - **Get started with classifiers**. Classifying content and then labeling it so it can be protected and handled properly is the starting place for the information protection discipline. See Learn about trainable classifiers (preview).
- **Visit your Microsoft 365 solution catalog often**, and make sure to review new solutions to help you with your compliance needs. Sign in at https://compliance.microsoft.com and then select **Catalog** in the left navigation pane.

Use your free Azure Active Directory subscription

11/2/2020 • 2 minutes to read • Edit Online

If your organization has a paid subscription to Microsoft 365, Microsoft Dynamics CRM Online, Enterprise Mobility Suite, or other Microsoft services, you have a free subscription to Microsoft Azure Active Directory. You and other admins can use Azure AD to create and manage user and group accounts. To use Azure AD, just go to the Azure portal and sign in to your account.

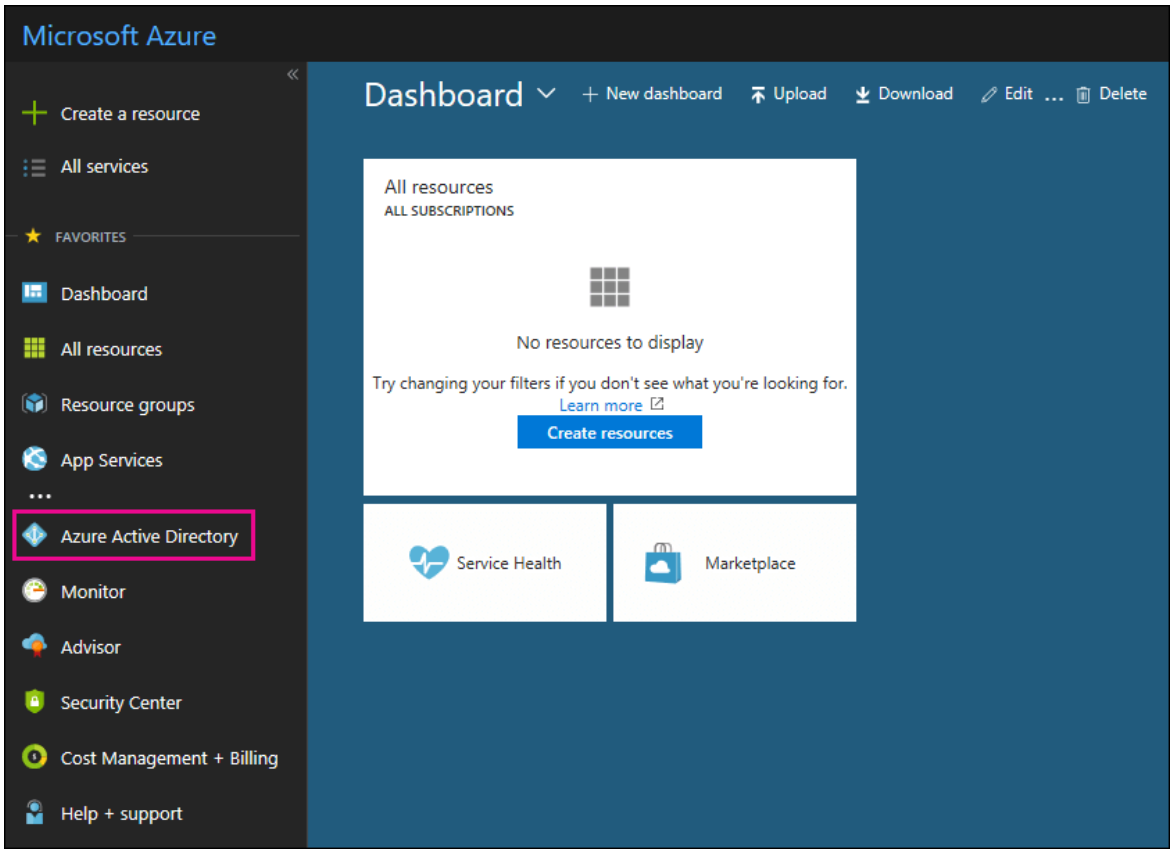
Open a private browsing session

Use a private browsing session (not a regular session) to access the Azure portal (in step 1 below). This prevents the credentials that you're currently logged on with from being passed to Azure. To open a private browsing session:

- In Microsoft Edge (legacy version), Internet Explorer, or Mozilla FireFox, press `CTRL+SHIFT+P`.
- In Microsoft Edge (newest version) or Google Chrome, press `CTRL+SHIFT+N`.

Access Azure Active Directory

1. Go to portal.azure.com and sign in with your work or student account.
2. In the left navigation pane in the Azure portal, click **Azure Active Directory**.



The **Azure Active Directory** admin center is displayed.

More information

- A free Azure Active Directory subscription does not include the Sign-ins activity report. To record sign-in

activity (which can be useful in a data breach), you need an Azure Active Directory Premium subscription. For more information, see How long does Azure AD store the data?.

- You can also access the **Azure Active Directory** admin center from the Microsoft 365 admin center. In the left navigation pane of the Microsoft 365 admin center, click **Admin centers** > **Azure Active Directory**.
- For information about managing users and groups and performing other directory management tasks, see Manage your Azure AD directory.

Plan for security & compliance

11/2/2020 • 2 minutes to read • Edit Online

Managing security and compliance is a partnership. You are responsible for protecting your data, identities, and devices, while Microsoft vigorously protects Microsoft 365 services. You can use Microsoft 365 and Enterprise Mobility + Security (EMS) together to help you achieve the appropriate level of protection for your organization.

Step 1: Review capabilities

Orient yourself to the information protection capabilities in the Information Protection for Office 365 poster.

Deploy information protection for data privacy regulations with Microsoft 365

Step 2: Check your Secure Score

After setting up your Microsoft 365 subscription, take note of your starting score. Secure Score provides configuration suggestions that you can take to increase your score. The goal is to be aware of opportunities that you can take to protect your environment which won't negatively affect the productivity of your users.

- Introducing the Office 365 Secure Score

Step 3: Plan access protection for identity and devices

Protecting access to your Microsoft 365 data and services is crucial to defending against cyberattacks and guarding against data loss.

- Protect access to data and services in Office 365
- Secure email policies and configurations

PDF | Visio | More languages

Step 4: Plan data protection based on data sensitivity

Review and plan for file protection capabilities organized by three levels of protection.

PDF | Visio

Step 5: Leverage the Microsoft 365 Security & Compliance Center

The Security & Compliance Center gives you a single view into the controls you will use to manage the spectrum of Microsoft 365 security, including threat management, data governance, and search and investigation.

- Go to the Security & Compliance Center
- Permissions in the Security & Compliance Center
- Give users access to the Security & Compliance Center

Step 6: Use end-to-end security scenarios as starting points

Use these recommended configurations as a starting point for enterprise scale or sophisticated access security

scenarios.

- Secure email policies and configurations
- Contoso in the Microsoft Cloud

Microsoft 365 admin centers and dashboards

Configure your security and compliance settings in these admin centers and dashboards to protect your Microsoft 365 environment

Microsoft 365 compliance extensibility

11/2/2020 • 4 minutes to read • Edit Online

Microsoft 365 compliance solutions help organizations intelligently assess their compliance risks, govern and protect sensitive data, and effectively respond to regulatory requirements. Microsoft 365 compliance is rich in extensibility scenarios and enables organizations to adapt, extend, integrate, accelerate, and support their compliance solutions.

There are two key building blocks for compliance extensibility:

- **Data connectors**. Use to import and archive non-Microsoft data so you can apply Microsoft 365 protection and governance capabilities to third-party data.
- **APIs**. Enables programmatic access to Microsoft 365 compliance capabilities.

Data connectors

Microsoft provides third-party data connectors that can be configured in the Microsoft 365 compliance center. For a list of data connectors provided by Microsoft, see the Third-party data connectors table. The table of third-party data connectors also summarizes the compliance solutions that you can apply to third-party data after you import and archive data in Microsoft 365, and links to the step-by-step instructions for each connector.

To learn more about Microsoft 365 data connectors, see Archiving third-party data. If a third-party data type isn't supported by the data connectors available in the Microsoft 365 compliance center, you can work with a partner who can provide you with a custom connector. For a list of partners you can work with and the step-by-step process for this method, see Work with a partner to archive third-party data.

Prerequisites for data connectors

Many of the data connectors available in the Microsoft 365 compliance center to import and archive third-party data require that you prepare and perform configuration tasks in the third-party data source. These prerequisites are documented in detail for each third-party data connector.

For data connectors in the Microsoft 365 compliance center provided by one of Microsoft's partners, your organization will need a business relationship with the partner before you can deploy a connector.

You can find licensing requirements for third-party data connectors in the Microsoft 365 Compliance Licensing Comparison document.

APIs

Microsoft 365 compliance APIs are available in the Microsoft Information Protection SDK, Microsoft Graph API, and the Office 365 Management Activity API. Some compliance APIs are part of a new set of security and compliance APIs that enable developers for Microsoft 365 customers, independent software vendors, system integrators, and managed security service providers to build high-value security and compliance solutions.

To learn more about how to access Graph APIs, see Overview of Microsoft Graph.

Microsoft Information Protection (MIP) SDK

The MIP SDK exposes the labeling and protection services from Microsoft 365 security and compliance centers to third-party applications and services. Developers can use the SDK to build native support for applying labels and protection to files. Developers can determine which actions should be taken when specific labels are detected, and reason over MIP-encrypted information.

High-level MIP SDK use cases include:

- A line-of-business application that applies classification labels to files on export.
- A CAD/CAM design application that provides native support for MIP labeling.
- A cloud access security broker or data loss prevention solution that can encrypt data with Azure Information Protection.

To learn more about the MIP SDK, prerequisites, additional scenarios, and samples, see MIP SDK Overview.

Microsoft Graph API for Teams DLP

Data loss prevention (DLP) capabilities are widely used in Microsoft Teams particularly as organizations have shifted to remote work. Earlier this year we announced the public preview of the Microsoft Graph Change Notification API for messages in Teams. This API enables developers to build apps that can listen to Microsoft Teams messages in near-real time and then implement DLP scenarios for both customers and partners. Additionally, Microsoft Graph Patch API lets you apply DLP actions to Teams messages.

These two APIs form the Microsoft Graph API for Teams DLP. You can get started by trying out the sample app. For more information about Microsoft Teams messaging webhooks, see the documentation.

For the licensing requirements for Teams DLP, see Microsoft 365 licensing guidance for security & compliance.

Microsoft Graph API for eDiscovery (preview)

With Advanced eDiscovery, organizations can discover data where it lives, and manage more end-to-end eDiscovery workflows with intelligent machine-learning and analytics capabilities to reduce data to the relevant set – all while the data stays within the Microsoft 365 security and compliance boundary.

Graph APIs for Advanced eDiscovery can be used to create and manage cases, review sets, and review set queries in a scalable and repeatable manner. This enables customers and partners to create apps and workflows to automate common and repetitive processes such as creating cases and managing custodians and legal holds.

The first set of Graph APIs for eDiscovery are available in public preview. We plan to add more capabilities by the end of the calendar year. To learn more about these APIs and other updates for Advanced eDiscovery, see this blog.

For the licensing requirements for Advanced eDiscovery and the API, see the "eDiscovery" section in the Microsoft 365 licensing guidance for security & compliance.

Microsoft Graph API for Teams Export (preview)

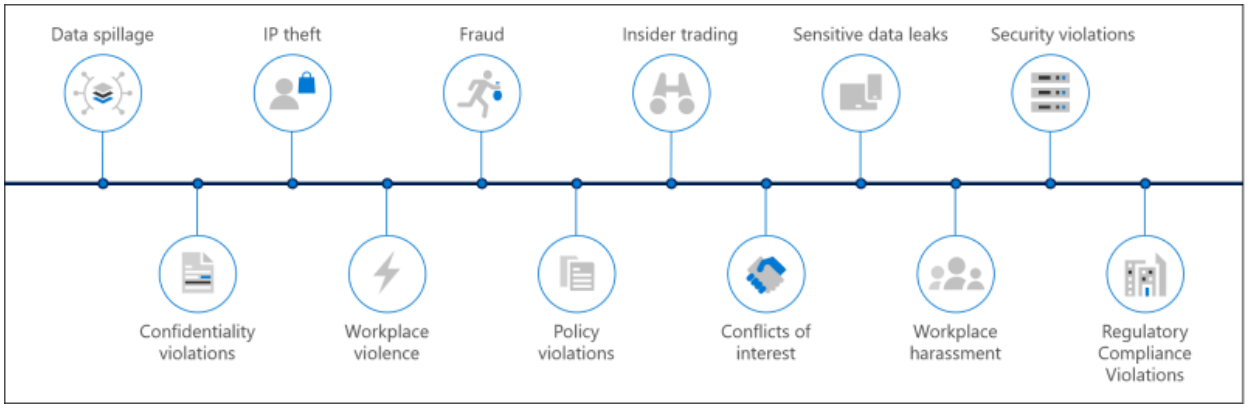
Enterprise Information Archiving (EIA) for Microsoft Teams is a key scenario for our customers as it allows them to solve for regulatory requirements. In addition to our built-in capabilities for archiving content in Microsoft Teams, customers and partners can now use Teams Export APIs to solve for custom application and integration scenarios. The Teams Export APIs support bulk-export (up to 200 requests per second/per app/per tenant) of Teams messages and message attachments. Deleted messages are also accessible by the API for up to 30 days after they are deleted. For more information about these Teams Export APIs and how to use them in your applications, see Export content with the Microsoft Teams Export APIs.

For the licensing requirements for the use of the Teams Export APIs, see Microsoft 365 licensing guidance for security & compliance.

Insider risk solutions in Microsoft 365

2/18/2021 • 6 minutes to read • Edit Online

Insider risks are one of the top concerns of security and compliance professionals in the modern workplace. Industry studies have shown that insider risks are often associated with specific user events or activities. Protecting your organization against these risks can be challenging to identify and difficult to mitigate. Insider risks include vulnerabilities in a variety of areas and can cause major problems for your organization, ranging from the loss of intellectual property to workplace harassment, and more. The following figure outlines common insider risks:



Microsoft 365 risk prevention features are designed and built-in to our insider risk products and solutions. These solutions work together and use advanced service and 3rd-party indicators to help you quickly identify, triage, and act on risk activity. Most solutions offer a comprehensive detection, alert, and remediation workflow for your data analysts and investigators to use to quickly act on and minimize these risks.

Microsoft 365 insider risk solutions

To help protect your organization against insider risks, use these Microsoft 365 capabilities and features.

Communication compliance

Communication compliance helps minimize communication risks by helping you detect, capture, and act on inappropriate messages in your organization. Communication compliance is available in the following subscriptions:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Microsoft 365 G5 subscription (paid or trial version)
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Compliance add-on
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Insider Risk Management add-on
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 A5 subscription (paid or trial version)
- Office 365 Enterprise E3 subscription + the Office 365 Advanced Compliance add-on (no longer available for new subscriptions)

Insider risk management

Insider risk management helps minimize internal risks by enabling you to detect, investigate, and act on malicious and inadvertent activities in your organization.

Insider risk management is available in the following subscriptions:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)

- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Microsoft 365 G5 subscription (paid or trial version)
- Microsoft 365 G3 subscription + the Microsoft 365 G5 Compliance add-on
- Microsoft 365 G3 subscription + the Microsoft 365 G5 Insider Risk Management add-on
- Office 365 E3 subscription + Enterprise Mobility and Security E3 + the Microsoft 365 E5 Compliance add-on

Information barriers

Information barriers allow you to restrict communication and collaboration between two internal groups to avoid a conflict of interest from occurring in your organization.

Information barriers are available in the following subscriptions:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 A5 subscription (paid or trial version)
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 A5 subscription (paid or trial version)
- Office 365 Advanced Compliance add-on (no longer available for new subscriptions)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on

Privileged access management

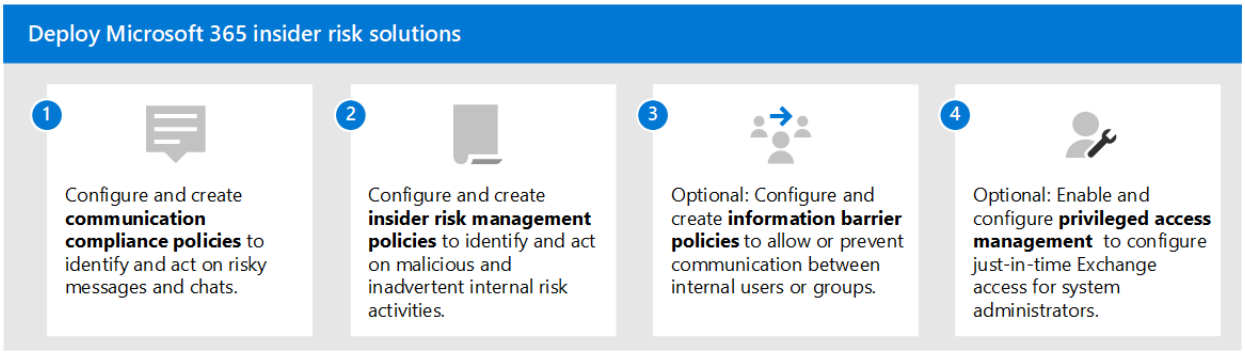
Privileged access management allows granular access control over privileged Exchange Online admin tasks in Office 365. It can help protect your organization from breaches that use existing privileged admin accounts with standing access to sensitive data or access to critical configuration settings.

Privileged access management is available in the following subscriptions:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 A5 subscription (paid or trial version)
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 A5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Information Protection and Governance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Information Protection and Governance add-on

Deploy Microsoft 365 insider risk solutions

To help protect your organization against insider risks, set up and deploy the following Microsoft 365 solutions:



1. Configure and create communication compliance policies.
2. Configure and create insider risk management policies.
3. Optional: Configure and create information barrier policies.
4. Optional: Enable and configure privileged access management.

Illustrations with examples

To help you plan an integrated strategy for implementing Microsoft 365 insider risk capabilities, download the *Microsoft 365 information protection and compliance capabilities* set of illustrations. For insider risk capabilities, see the architecture illustration pages 5-7. Feel free to adapt these illustrations for your own use.

ITEM	DESCRIPTION
 Download as a PDF | Download as a Visio Updated October 2020	Includes: • Microsoft information protection and data loss prevention • Retention policies and retention labels • Information barriers • Communication compliance • Insider risk management • Third-party data ingestion

Training

Training your administrators and compliance team in the basics for each insider risk solution can help your organization get started more quickly with your deployment and implementation efforts.

Microsoft 365 provides the following resources to help inform and train these users in your organization:

SOLUTION/AREA	RESOURCES
Manage insider risk in Microsoft 365	Complete learning path This learning path includes all the individual solution modules for communication compliance, insider risk management, information barriers, and privileged access management. Select this learning path to complete all the modules.
Communication compliance	Learning module: Prepare communication compliance in Microsoft 365 This module helps you learn the basics on how to identify and remediate code-of-conduct policy violations with communication compliance, cover the prerequisites needed before creating communication compliance policies, and learn about the types of built-in, pre-defined policy templates in communication compliance.

SOLUTION/AREA	RESOURCES
Insider risk management	Learning module: Insider risk management in Microsoft 365 This module helps you learn how insider risk management in Microsoft 365 can help prevent, detect, and contain internal risks in an organization, learn about the types of built-in, pre-defined policy templates, understand the basic prerequisites needed before creating insider risk policies, and explains the types of actions you can take on insider risk management cases.
Information barriers	Learning module: Plan for information barriers This module helps you learn how information barrier policies can help your organization maintain compliance with relevant industry standards and regulations, lists the types of situations when information barriers would be applicable, helps explain the process of creating an information barrier policy, and helps explain how to troubleshoot unexpected issues after information barriers are in place.
Privileged access management	Learning module: Implement privileged access management This module helps you understand the difference between privileged access management and privileged identity management, understand the privileged access management process flow, and understand the basics of how to configure and enable privileged access management.

Communication compliance in Microsoft 365

2/18/2021 • 2 minutes to read • Edit Online

Protecting sensitive information and detecting and acting on workplace harassment incidents is an important part of compliance with internal policies and standards. Communication compliance in Microsoft 365 helps minimize these risks by helping you quickly detect, capture, and take remediation actions for email and Microsoft Teams communications. These include inappropriate communications containing profanity, threats, and harassment and communications that share sensitive information inside and outside of your organization.

Configure communication compliance for Microsoft 365

Use the following steps to configure communication compliance for your organization:

1. Learn about communication compliance in Microsoft 365
2. Plan for communication compliance and verify licensing
3. Review feature reference and solution capabilities
4. Configure prerequisites and permissions
5. Create and configure communication compliance policies

More information about communication compliance

- Investigate and remediate alerts
- Case study - Contoso quickly configures an offensive language policy for Microsoft Teams, Exchange, and Yammer communications

Learn about communication compliance in Microsoft 365

2/18/2021 • 11 minutes to read • Edit Online

Communication compliance is an insider risk solution in Microsoft 365 that helps minimize communication risks by helping you detect, capture, and act on inappropriate messages in your organization. Pre-defined and custom policies allow you to scan internal and external communications for policy matches so they can be examined by designated reviewers. Reviewers can investigate scanned email, Microsoft Teams, Yammer, or third-party communications in your organization and take appropriate actions to make sure they're compliant with your organization's message standards.

Communication compliance policies in Microsoft 365 help you overcome many modern challenges associated with compliance and internal and external communications, including:

- Scanning increasing types of communication channels
- The increasing volume of message data
- Regulatory enforcement and the risk of fines

Additionally, there may be a separation of duties between your IT admins and your compliance management team. Communication compliance supports the separation between configuration of policies and the investigation and review of messages. For example, the IT group for your organization may be responsible for setting up communication compliance role permissions, groups, and policies and investigators and reviewers may be responsible for message triage, review, and mitigation actions.

For a quick overview of communication compliance, see the Detect workplace harassment and respond with Communication Compliance in Microsoft 365 video on the Microsoft Mechanics channel.

Scenarios for communication compliance

Communication compliance policies can assist with reviewing messages in your organization in several important compliance areas:

- **Corporate policies**

  Users must comply with acceptable use, ethical standards, and other corporate policies in all their business-related communications. Communication compliance policies can detect policy matches and help you take corrective actions to help mitigate these types of incidents. For example, you could scan user communications in your organization for potential human resources concerns such as harassment or the use of inappropriate or offensive language.

- **Risk management**

  Organizations are responsible to all communications distributed throughout their infrastructure and corporate network systems. Using communication compliance policies to help identify and manage potential legal exposure and risk can help minimize risks before they can damage corporate operations. For example, you could scan messages in your organization for unauthorized communications and conflicts of interest about confidential projects such as upcoming acquisitions, mergers, earnings disclosures, reorganizations, or leadership team changes.

- **Regulatory compliance**

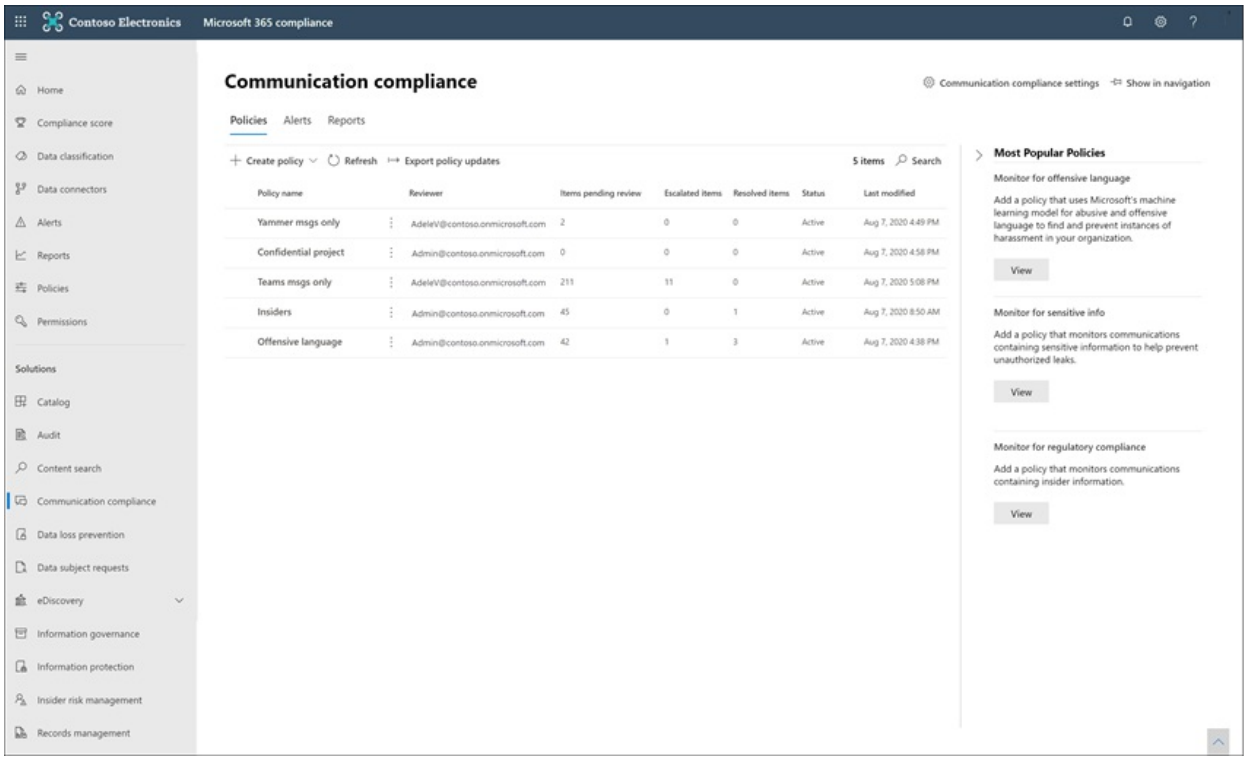
  Most organizations must comply with some type of regulatory compliance standards as part of their

normal operating procedures. These regulations often require organizations to implement some type of supervisory or oversight process for messaging that is appropriate for their industry. The Financial Industry Regulatory Authority (FINRA) Rule 3110 is a good example of a requirement for organizations to have supervisory procedures in place to scan user communications and the types of businesses in which it engages. Another example may be a need to review broker-dealer communications in your organization to safeguard against potential money laundering, insider trading, collusion, or bribery activities. Communication compliance policies can help your organization meet these requirements by providing a process to both scan and report on corporate communications. For more information on support for financial organizations, see Key compliance and security considerations for US banking and capital markets.

Key feature areas

Communication compliance in Microsoft 365 offers several important features to help address compliance concerns on your messaging platforms:

- Intelligent customizable templates
- Flexible remediation workflows
- Actionable insights



Intelligent customizable templates

Intelligent customizable templates in communication compliance allow you to apply machine learning to intelligently detect communication violations in your organization.

- **Customizable pre-configured templates**: New policy templates help address the most common communications risks. Initial policy creation and follow-on updating are now quicker with pre-defined anti-harassment and offensive language, sensitive information, conflict of interest, and regulatory compliance templates.
- **New machine learning support**: Built-in threat, harassment, profanity, and image classifiers help reduce false positives in scanned messages, saving reviewers time during the investigation and remediation process.
- **Improved condition builder**: Configuring policy conditions is now streamlined into a single, integrated experience in the policy wizard, reducing confusion in how conditions are applied for policies.

Flexible remediation workflows

Built-in remediation workflows allow you to quickly identify and take action on messages with policy matches in your organization. The following new features increase efficiency for investigation and remediation activities:

- **Flexible remediation workflow**: New remediation workflow helps you quickly take action on policy matches, including new options to escalate messages to other reviewers and to send email notifications to users with policy matches.
- **Conversation threading**: Messages are now visually grouped by original message and all associated reply messages, giving you better context during investigation and remediation actions.
- **Keyword highlighting**: Terms matching policy conditions are highlighted in the message text view to help reviewers quickly locate and remediate policy alerts.
- **Exact and near duplicate detection**: In addition to scanning for exact terms matching communication compliance policies, near duplicate detection groups textually similar terms and messages together to help speed up your review process.
- **New filters**: Investigate and remediate policy alerts faster with message filters for several fields, including sender, recipient, date, domains, and many more.
- **Improved message views**: Investigation and remediation actions are now quicker with new message source, text, and annotation views. Message attachments are now viewable to provide complete context when taking remediation actions.
- **User history view**: Historical view of all user message remediation activities, such as past notifications and escalations for policy matches, now provides reviewers with more context during the remediation workflow process. First-time or repeat instances of policy matches for users are now archived and easily viewable.
- **Pattern detected notification**: Many harassing and bullying actions take place over time and involve reoccurring instances of the same behavior by a user. The new Pattern detected notification displayed in alert details helps raise attention to these alerts and this type of behavior.
- **Show Translate view**: Quickly investigate message details in other languages using translate support in the remediation workflow. Messages in other languages are automatically converted to the display language of the reviewer.

Actionable insights

New interactive dashboards for alerts, policy matches, actions, and trends help you quickly view the status of pending and resolved alerts in your organization.

- **Proactive intelligent alerts**: Alerts for policy matches requiring immediate attention include new dashboards for pending items sorted by severity and new automatic email notifications sent to designated reviewers.
- **Interactive dashboards**: New dashboards display policy matches, pending and resolved actions, and trends by users and policy.
- **Auditing support**: A full log of policy and review activities is easily exported from the Microsoft 365 compliance center to help support audit review requests.

Integration with Microsoft 365 services

Communication compliance policies scan and capture messages across several communication channels to help you quickly review and remediate compliance issues:

- **Microsoft Teams**: Chat communications for public and private Microsoft Teams channels and individual chats are supported in communication compliance as a standalone channel source or with other Microsoft 365 services. You'll need to manually add individual users, distribution groups, or specific Microsoft Teams channels when you select users and groups to supervise in a communication compliance policy.
- **Exchange Online**: All mailboxes hosted on Exchange Online in your Microsoft 365 organization are eligible for scanning. Emails and attachments matching communication compliance policy conditions are instantly available for monitoring and in compliance reports. Exchange Online is now an optional source channel and

is no longer required in communication compliance policies.

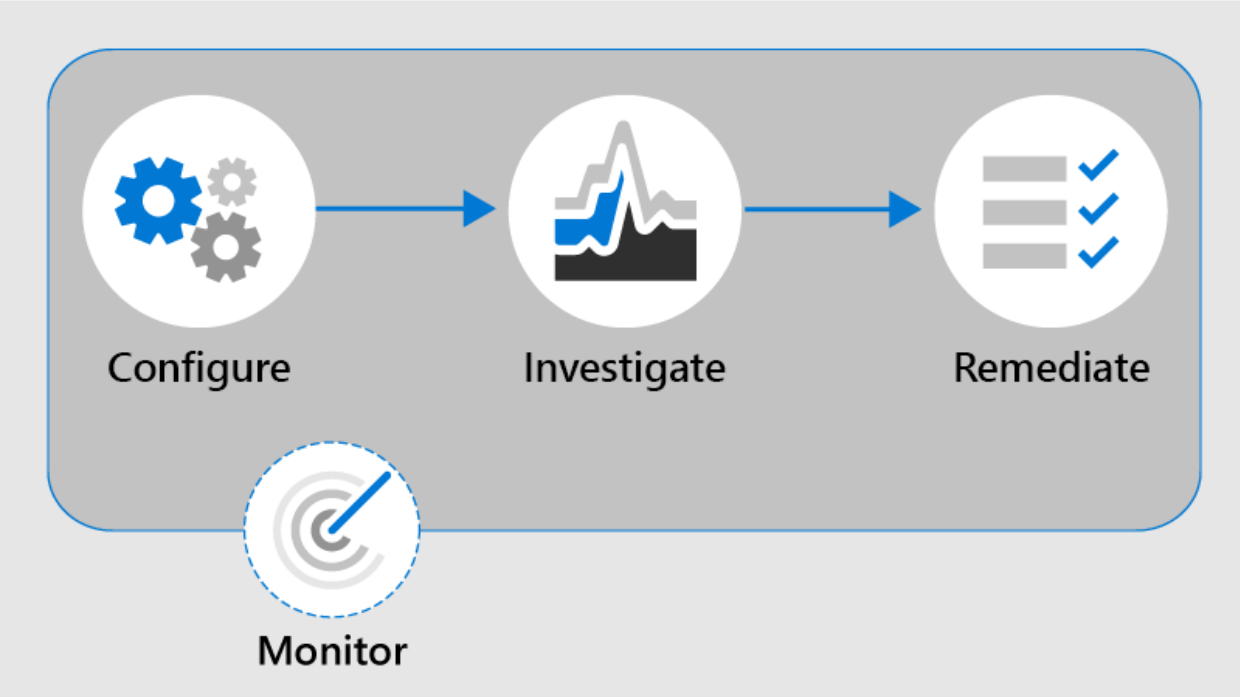
- **Yammer**: Private messages and public community conversations in Yammer are supported in communication compliance policies. Yammer is an optional channel and must be in native mode to support scanning of messages and attachments.
- **Skype for Business Online**: Communication compliance policies support scanning chat communications and associated attachments in Skype for Business Online.
- **Third-party sources**: You can scan messages from third-party sources for data imported into mailboxes in your Microsoft 365 organization. Communication compliance supports connections to several popular platforms, including Instant Bloomberg and others.

To learn more about messaging channel support in communication compliance policies, see supported communication types.

Workflow

Communication compliance helps you address common pain points associated with complying with internal policies and regulatory compliance requirements. With focused policy templates and a flexible workflow, you can use actionable insights to quickly resolve detected compliance issues.

Identifying and resolving compliance issues with communication compliance in Microsoft 365 uses the following workflow:



Configure

In this workflow step, you identify your compliance requirements and configure applicable communication compliance policies. Policy templates are a great way to not only quickly configure a new compliance policy, but to also quickly modify and update policies as your requirements change. For example, you may want to quickly test a policy for offensive language and anti-harassment on communications for a small group of users before configuring a policy for all users in your organization.

> **IMPORTANT**
> By default, Global Administrators do not have access to communication compliance features. To enable permissions for communication compliance features, see Make communication compliance available in your organization.

You can choose from the following policy templates in the Microsoft 365 compliance center:

- **Offensive or threatening language**: Use this template to quickly create a policy that uses built-in classifiers to automatically detect content that may be considered abusive or offensive.
- **Sensitive information**: Use this template to quickly create a policy to scan communications containing defined sensitive information types or keywords to help make sure that important data isn't shared with people that shouldn't have access.
- **Regulatory compliance**: Use this template to quickly create a policy to scan communications for references to standard financial terms associated with regulatory standards.
- **Conflict of interest**: Use this template to quickly create a policy to monitor communications between two groups or two users to help avoid conflicts of interest.
- **Custom policy**: Use this template to configure specific communication channels, individual detection conditions, and the amount of content to monitor and review in your organization.

Investigate

In this step, you look deeper into the issues detected as matching your communication compliance policies. This step includes the following actions available in the Microsoft 365 compliance center:

- **Alerts**: When a message matches a policy condition, an alert is automatically generated. For each alert, you can see the status, the severity, the time detected, and if an Advanced eDiscovery case is assigned and its status. New alerts are displayed on the communication compliance home page and the **Alerts** page and are listed in order of severity.
- **Issue management**: For each alert, you can take investigative actions to help remediate the issue detected in the message.
- **Document review**: During the investigation of an issue, you can use several views of the message to help properly evaluate the detected issue. The views include a conversation summary, text-only, annotated, and detail views of the communication conversation.
- **Reviewing user activity history**: View the history of user message activities and remediation actions, such as past notifications and escalations, for policy matches.
- **Filters**: Use filters such as sender, recipient, date, and subject to quickly narrow down the message alerts that you want to review.

Remediate

The next step is to remediate communication compliance issues you've investigated using the following options:

- **Resolve**: After reviewing an issue, you can remediate by resolving the alert. Resolving an alert removes it from the pending alert queue, and the action is preserved as an entry in the Resolved queue for the matching policy. Alerts are automatically resolved after marking the alert as a false positive, sending a notice to a user about the alert, or opening a new case for the alert.
- **Tag a message**: As part of the resolution of an issue, you can tag the detected message as compliant, non-compliant, or as questionable as it relates to the policies and standards for your organization. Tagging can help you micro-filter policy alerts for escalations or as part of other internal review processes.
- **Notify the user**: Often, users accidentally or inadvertently violate a communication compliance policy. You can use the notify feature to provide a warning notice to the user and to resolve the issue.
- **Escalate to another reviewer**: Sometimes, the initial reviewer of an issue needs input from other reviewers to help resolve the incident. You can easily escalate message issues to reviewers in other areas of your organization as part of the resolution process.
- **Mark as a false positive**: Messages incorrectly detected as matches of compliance policies will occasionally slip through to the review process. You can mark these types of alerts as false positives and automatically resolve the issue.
- **Remove message in Teams (preview)**: Inappropriate messages may be removed from displaying in Microsoft Teams channels or personal and group chat messages. Inappropriate messages that are removed are replaced with a notification that the message has been removed for a policy violation.

- **Escalate for investigation**: In the most serious situations, you may need to share communication compliance information with other reviewers in your organization. Communication compliance is tightly integrated with other Microsoft 365 compliance features to help you with end-to-end risk resolution. Escalating a case for investigation allows you to transfer data and management of the case to Advanced eDiscovery in Microsoft 365. Advanced eDiscovery provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. It allows legal teams to manage the entire legal hold notification workflow. To learn more about Advanced eDiscovery cases, see Overview of Advanced eDiscovery in Microsoft 365.

Monitor

Keeping track and managing compliance issues identified by communication compliance policies spans the entire workflow process. As alerts are generated and investigation and remediation actions are implemented, existing policies may need review and updates, and new policies may need to be created.

- **Monitor and report**: Use communication compliance dashboard widgets, export logs, and events recorded in the unified audit logs to continually evaluate and improve your compliance posture.

Ready to get started?

- For planning information, see Plan for communication compliance.
- Check out the case study for Contoso and see how they quickly configured a communication compliance policy to monitor for offensive language in Microsoft Teams, Exchange Online, and Yammer communications.
- To configure communication compliance for your Microsoft 365 organization, see Configure communication compliance for Microsoft 365.

Plan for communication compliance

11/2/2020 • 4 minutes to read • Edit Online

Before getting started with communication compliance in your organization, there are important planning activities and considerations that should be reviewed by your information technology and compliance management teams. Thoroughly understanding and planning for deployment in the following areas will help ensure that your implementation and use of communication compliance features goes smoothly and is aligned with the best practices for the solution.

Work with stakeholders in your organization

Identify the appropriate stakeholders in your organization to collaborate for taking actions on communication compliance alerts. Some recommended stakeholders to consider including in initial planning and the end-to-end communication compliance workflow are people from the following areas of your organization:

- Information technology
- Compliance
- Privacy
- Security
- Human resources
- Legal

Plan for the investigation and remediation workflow

Select dedicated stakeholders to monitor and review the alerts and cases on a regular cadence in the Microsoft 365 compliance center. Make sure understand how you will assign users and stakeholders to different communication compliance role groups in your organization.

Depending on how you wish to manage communication policies and alerts, you'll need to assign users to one or more role groups for administrators, reviewers, and investigators. You have the option to assign users to specific role groups to manage different sets of communication compliance features. Or you may decide to assign all the communication compliance users to the Communication Compliance role group. Use a single role group or multiple groups to best fit your compliance management requirements.

Plan to choose from these role group options when configuring communication compliance:

ROLE	ROLE PERMISSIONS
Communication Compliance	Use this role group to manage communication compliance for your organization in a single group. By adding all user accounts for designated administrators, analysts, investigators, and viewers, you can configure communication compliance permissions in a single group. This role group contains all the communication compliance permission roles. This configuration is the easiest way to quickly get started with communication compliance and is a good fit for organizations that do not need separate permissions defined for separate groups of users.

ROLE	ROLE PERMISSIONS
Communication Compliance Admin	Use this role group to initially configure communication compliance and later to segregate communication compliance administrators into a defined group. Users assigned to this role group can create, read, update, and delete communication compliance policies, global settings, and role group assignments. Users assigned to this role group cannot view message alerts.
Communication Compliance Analyst	Use this group to assign permissions to users that will act as communication compliance analysts. Users assigned to this role group can view policies where they are assigned as Reviewers, view message metadata (not message content), escalate to additional reviewers, or send notifications to users. Analysts cannot resolve pending alerts.
Communication Compliance Investigator	Use this group to assign permissions to users that will act as communication compliance investigators. Users assigned to this role group can view message metadata and content, escalate to additional reviewers, escalate to an Advanced eDiscovery case, send notifications to users, and resolve the alert.
Communication Compliance Viewer	Use this group to assign permissions to users that will manage communication reports. Users assigned to this role group can access all reporting widgets on the communication compliance home page and can view all communication compliance reports.

Plan for policies

Creating communication compliance policies is quick and easy with the pre-defined templates for offensive language, sensitive information, and regulatory compliance. Custom communication compliance policies allow the flexibility for detecting and investigation issues specific to your organization and requirements.

When planning for communication compliance policies, consider the following areas:

- Consider adding all users in your organization as in-scope for your communication compliance policies. Identifying specific users as in-scope for individual policies are useful in some circumstances, however most organizations should include all users in communication compliance policies optimized for harassment or discrimination detection.
- To simplify your setup, consider creating groups for people who need their communications reviewed. If you're using groups; you might need several. For example, if you want to scan communications between two distinct groups of people, or if you want to specify a group that isn't supervised.
- Configure the percentage of communications to review at 100% to ensure that policies are catching all issues of concern in communications for your organization.
- You can scan communications from third-party sources for data imported into mailboxes in your Microsoft 365 organization. To include review of communications in these platforms, you'll need to configure a connector to these services before messages meeting policy conditions are monitored by communication policy.
- Policies can support monitoring languages other than English in custom communication compliance policies. Build a custom keyword dictionary of offensive words in the language of your choice or build your own machine-learning model using trainable classifiers in Microsoft 365.
- All organizations have different communication standards and policy needs. Monitor for specific keywords using communication compliance policy conditions or monitor for specific types of information with custom

sensitive information types.

Ready to get started?

To configure communication compliance for your Microsoft 365 organization, see Configure communication compliance for Microsoft 365 or check out the case study for Contoso and how they quickly configured a communication compliance policy to monitor for offensive language in Microsoft Teams, Exchange Online, and Yammer communications.

Get started with communication compliance

2/18/2021 • 15 minutes to read • Edit Online

Use communication compliance policies to identify user communications for examination by internal or external reviewers. For more information about how communication compliance policies can help you monitor communications in your organization, see communication compliance policies in Microsoft 365. If you'd like to review how Contoso quickly configured a communication compliance policy to monitor for offensive language in Microsoft Teams, Exchange Online, and Yammer communications, check out this case study.

Subscriptions and licensing

Before you get started with communication compliance, you should confirm your Microsoft 365 subscription and any add-ons. To access and use communication compliance, your organization must have one of the following subscriptions or add-ons:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Microsoft 365 G5 subscription (paid or trial version)
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Compliance add-on
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Insider Risk Management add-on
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 A5 subscription (paid or trial version)
- Office 365 Enterprise E3 subscription + the Office 365 Advanced Compliance add-on (no longer available for new subscriptions, see note)

Users included in communication compliance policies must be assigned one of the licenses above.

> **IMPORTANT**
> Office 365 Advanced Compliance is no longer sold as a standalone subscription. When current subscriptions expire, customers should transition to one of the subscriptions above, which contain the same or additional compliance features.

If you don't have an existing Office 365 Enterprise E5 plan and want to try communication compliance, you can add Microsoft 365 to your existing subscription or sign up for a trial of Office 365 Enterprise E5.

Step 1 (required): Enable permissions for communication compliance

> **IMPORTANT**
> By default, Global Administrators do not have access to communication compliance features. The roles assigned in this step are required before any communication compliance features will be accessible. After configuring your role groups, it may take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

There are five role groups used to configure permissions to manage communication compliance features. To

make **Communication compliance** available as a menu option in Microsoft 365 compliance center and to continue with these configuration steps, you must be assigned to the *Communication Compliance* or *Communication Compliance Admin* role groups. To access and manage communication compliance features after initial configuration, users must be a member of at least one communication compliance role group.

Depending on how you wish to manage communication policies and alerts, you'll need to assign users to specific role groups. You have the option to assign users with different compliance responsibilities to specific role groups to manage different areas of communication compliance features. Or you may decide to assign all user accounts for designated administrators, analysts, investigators, and viewers to the *Communication Compliance* role group. Use a single role group or multiple role groups to best fit your compliance management requirements.

Choose from these role group options when configuring communication compliance:

ROLE	ROLE PERMISSIONS
Communication Compliance	Use this role group to manage communication compliance for your organization in a single group. By adding all user accounts for designated administrators, analysts, investigators, and viewers, you can configure communication compliance permissions in a single group. This role group contains all the communication compliance permission roles. This configuration is the easiest way to quickly get started with communication compliance and is a good fit for organizations that do not need separate permissions defined for separate groups of users.
Communication Compliance Admin	Use this role group to initially configure communication compliance and later to segregate communication compliance administrators into a defined group. Users assigned to this role group can create, read, update, and delete communication compliance policies, global settings, and role group assignments. Users assigned to this role group cannot view message alerts.
Communication Compliance Analyst	Use this group to assign permissions to users that will act as communication compliance analysts. Users assigned to this role group can view policies where they are assigned as Reviewers, view message metadata (not message content), escalate to additional reviewers, or send notifications to users. Analysts cannot resolve pending alerts.
Communication Compliance Investigator	Use this group to assign permissions to users that will act as communication compliance investigators. Users assigned to this role group can view message metadata and content, escalate to additional reviewers, escalate to an Advanced eDiscovery case, send notifications to users, and resolve the alert.
Communication Compliance Viewer	Use this group to assign permissions to users that will manage communication reports. Users assigned to this role group can access all reporting widgets on the communication compliance home page and can view all communication compliance reports.

Option 1: Assign all compliance users to the Communication Compliance role group

1. Sign into https://protection.office.com/permissions using credentials for an admin account in your Microsoft 365 organization.

2. In the Security & Compliance Center, go to **Permissions**. Select the link to view and manage roles in Office 365.
3. Select the *Communication Compliance* role group, then select **Edit role group**.
4. Select **Choose members** from the left navigation pane, then select **Edit**.
5. Select **Add** and then select the checkbox for all users you want to add to the *Communication Compliance* role group.
6. Select **Add**, then select **Done**.
7. Select **Save** to add the users to the role group. Select **Close** to complete the steps

Option 2: Assign users to specific communication compliance role groups

Use this option to assign users to specific role groups to segment communication compliance access and responsibilities among different users in your organization.

1. Sign into https://protection.office.com/permissions using credentials for an admin account in your Microsoft 365 organization.
2. In the Security & Compliance Center, go to **Permissions**. Select the link to view and manage roles in Office 365.
3. Select one of the communication compliance role groups, then select **Edit role group**.
4. Select **Choose members** from the left navigation pane, then select **Edit**.
5. Select **Add** and then select the checkbox for all users you want to add to the role group.
6. Select **Add**, then select **Done**.
7. Select **Save** to add the users to the role group.
8. Select the next communication compliance role group, then repeat steps 4-7 for each required role group.
9. Select **Close** to complete the steps.

For more information about role groups and permissions, see Permissions in the Compliance Center.

Step 2 (required): Enable the audit log

Communication compliance requires audit logs to show alerts and track remediation actions taken by reviewers. The audit logs are a summary of all activities associated with a defined organizational policy or anytime a communication compliance policy changes.

For step-by-step instructions to turn on auditing, see Turn audit log search on or off. After you turn on auditing, a message is displayed that says the audit log is being prepared and that you can run a search in a couple of hours after the preparation is complete. You only have to do this action once. For more information about the using the audit log, see Search the audit log.

Step 3 (optional): Set up groups for communication compliance

When you create a communication compliance policy, you define who has their communications reviewed and who performs reviews. In the policy, you'll use email addresses to identify individuals or groups of people. To simplify your setup, you can create groups for people who have their communication reviewed and groups for people who review those communications. If you're using groups, you may need several. For example, if you want to monitor communications between two distinct groups of people or if you want to specify a group that isn't going to be supervised.

Use the following chart to help you configure groups in your organization for communication compliance policies:

POLICY MEMBER	SUPPORTED GROUPS	UNSUPPORTED GROUPS
Supervised users Non-supervised users	Distribution groups Microsoft 365 Groups	Dynamic distribution groups Nested distribution groups Mail-enabled security groups
Reviewers	None	Distribution groups Dynamic distribution groups Nested distribution groups Mail-enabled security groups

When you assign a distribution group in the policy, the policy monitors all emails and Teams chats from each user in distribution group. When you assign a Microsoft 365 group in the policy, the policy monitors all emails and Teams chats sent to that group, not the individual emails and chats received by each group member.

If you're an organization with an Exchange on-premises deployment or an external email provider and you want to monitor Microsoft Teams chats for your users, you must create a distribution group for the users with on-premises or external mailboxes to monitor. Later in these steps, you'll assign this distribution group as the **Supervised users and groups** selection in the policy wizard.

> **IMPORTANT**
> You must file a request with Microsoft Support to enable your organization to use the graphical user interface in the Security & Compliance Center to search for Teams chat data for on-premises users. For more information, see Searching cloud-based mailboxes for on-premises users.

To manage supervised users in large enterprise organizations, you may need to monitor all users across large groups. You can use PowerShell to configure a distribution group for a global communication compliance policy for the assigned group. This enables you to monitor thousands of users with a single policy and keep the communication compliance policy updated as new employees join your organization.

1. Create a dedicated distribution group for your global communication compliance policy with the following properties: Make sure that this distribution group isn't used for other purposes or other Office 365 services.

   - **MemberDepartRestriction = Closed**. Ensures that users cannot remove themselves from the distribution group.
   - **MemberJoinRestriction = Closed**. Ensures that users cannot add themselves to the distribution group.
   - **ModerationEnabled = True**. Ensures that all messages sent to this group are subject to approval and that the group is not being used to communicate outside of the communication compliance policy configuration.

   ```
   New-DistributionGroup -Name <your group name> -Alias <your group alias> -MemberDepartRestriction
   'Closed' -MemberJoinRestriction 'Closed' -ModerationEnabled $true
   ```

2. Select an unused Exchange custom attribute to track users added to the communication compliance policy in your organization.

3. Run the following PowerShell script on a recurring schedule to add users to the communication compliance policy:

```
$Mbx = (Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited -Filter {CustomAttribute9
-eq $Null})
$i = 0
ForEach ($M in $Mbx)
{
  Write-Host "Adding" $M.DisplayName
  Add-DistributionGroupMember -Identity <your group name> -Member $M.DistinguishedName -ErrorAction
SilentlyContinue
  Set-Mailbox -Identity $M.Alias -<your custom attribute name> SRAdded
  $i++
}
Write-Host $i "Mailboxes added to supervisory review distribution group."
```

For more information about setting up groups, see:

- Create and manage distribution groups
- Overview of Microsoft 365 Groups

Step 4 (optional): Verify your Yammer tenant is in Native Mode

In Native Mode, all Yammer users are in Azure Active Directory (Azure AD), all groups are Office 365 Groups, and all files are stored in SharePoint Online. Your Yammer tenant must be in Native Mode for communication compliance policies to scan and identify risky conversations in private messages and community conversations in Yammer.

For more information about configuring Yammer in Native Mode, see:

- Overview of Yammer Native Mode in Microsoft 365
- Configure your Yammer network for Native Mode for Microsoft 365

Step 5 (required): Create a communication compliance policy

> **IMPORTANT**
> Using PowerShell to create and manage communication compliance policies is not supported. To create and manage these policies, you must use the policy management controls in the Microsoft 365 communication compliance solution.

1. Sign into https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization.
2. In the Microsoft 365 compliance center, select **Communication compliance**.
3. Select the **Policies** tab.
4. Select **Create policy** to create and configure a new policy from a template or to create and configure a custom policy.

   If you choose a policy template to create a policy, you will:

   - Confirm or update the policy name. Policy names cannot be changed once the policy is created.
   - Choose the users or groups to supervise, including choosing users or groups you'd like to exclude. When using the conflict of interest template, you'll select two groups or two users to monitor for internal communications.
   - Choose the reviewers for the policy. Reviewers are individual users and all reviewers must have mailboxes hosted on Exchange Online. Reviewers added here are the reviewers that you can choose from when escalating an alert in the investigation and remediation workflow. When

reviewers are added to a policy, they automatically receive an email message that notifies them of the assignment to the policy and provides links to information about the review process.

- Choose a limited condition field, usually a sensitive info type or keyword dictionary to apply to the policy.

If you choose to use the policy wizard to create a custom policy, you will:

- Give the policy a name and description. Policy names can't be changed once the policy is created.
- Choose the users or groups to supervise, including all users in your organization, specific users and groups, or other users and groups you'd like to exclude.
- Choose the reviewers for the policy. Reviewers are individual users and all reviewers must have mailboxes hosted on Exchange Online. Reviewers added here are the reviewers that you can choose from when escalating an alert in the investigation and remediation workflow. When reviewers are added to a policy, they automatically receive an email message that notifies them of the assignment to the policy and provides links to information about the review process.
- Choose the communication channels to scan, including Exchange, Microsoft Teams, Yammer, or Skype for Business. You'll also choose to scan third-party sources if you've configured a connector in Microsoft 365.
- Choose the communication direction to monitor, including inbound, outbound, or internal communications.
- Define the communication compliance policy conditions. You can choose from message address, keyword, file types, and size match conditions.
- Choose if you'd like to include sensitive information types. This step is where you can select default and custom sensitive info types. Pick from existing custom sensitive information types or custom keyword dictionaries in the communication compliance policy wizard. You can create these items before running the wizard if needed. You can also create new sensitive information types from within the communication compliance policy wizard.
- Choose if you'd like to enable classifiers. Classifiers can detect inappropriate language and images sent or received in the body of email messages or other types of text. You can choose the following built-in classifiers: *Threat*, *Profanity*, *Targeted harassment*, *Adult images*, *Racy images*, and *Gory images*.

  Caution

  We are deprecating the **Offensive Language** built-in classifier because it has been producing a high number of false positives. Don't use it and if you are currently using it, you should move your business processes off of it. We recommend using the **Threat**, **Profanity**, and **Targeted harassment** built-in classifiers instead.
- Define the percentage of communications to review.
- Review your policy selections and create the policy.

5. Select **Create policy** when using the templates or **Submit** when using the custom policy wizard.
6. The **Your policy was created** page is displayed with guidelines on when policy will be activated and which communications will be captured.

Step 6 (optional): Create notice templates and configure user anonymization

If you want to have the option of responding to a policy alert by sending a reminder notice to the associated

user, you'll need to create at least one notice template in your organization. The notice template fields are editable before they're sent as part of the alert remediation process, and creating a customized notice template for each communication compliance policy is recommended.

You can also choose to enable anonymization for displayed usernames when investigating policy matches and taking action on messages.

1. Sign into https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization.
2. In the Microsoft 365 compliance center, go to **Communication compliance**.
3. To configure anonymization for usernames, select the **Privacy** tab.
4. To enable anonymization, select **Show anonymized versions of usernames**.
5. Select **Save**.
6. Navigate to the **Notice templates** tab and then select **Create notice template**.
7. On the **Modify a notice template** page, complete the following fields:
   - Template name (required)
   - Send from (required)
   - Cc and Bcc (optional)
   - Subject (required)
   - Message body (required)
8. Select **Save** to create and save the notice template.

Step 7 (optional): Test your communication compliance policy

After you create a communication compliance policy, it's a good idea to test it to make sure that the conditions you defined are being properly enforced by the policy. You may also want to test your data loss prevention (DLP) policies if your communication compliance policies include sensitive information types. Make sure you give your policies time to activate so that the communications you want to test are captured.

Follow these steps to test your communication compliance policy:

1. Open an email client, Microsoft Teams, or Yammer while signed in as a supervised user defined in the policy you want to test.
2. Send an email, Microsoft Teams chat, or Yammer message that meets the criteria you've defined in the communication compliance policy. This test can be a keyword, attachment size, domain, etc. Make sure you determine if your configured conditional settings in the policy are too restrictive or too lenient.

   > **NOTE**
   > Email messages can take up to 24 hours to fully process in a policy. Communications in Microsoft Teams, Yammer, and third-party platforms can take up to 48 hours to fully process in a policy.

3. Sign in to Microsoft 365 as a reviewer designated in the communication compliance policy. Navigate to **Communication compliance** > **Alerts** to view the alerts for your policies.
4. Remediate the alert using the remediation controls and verify that the alert is properly resolved.

Next steps

After you've completed these steps to create your first communication compliance policy, you'll start to receive alerts from activity indicators after 24-48 hours. Configure additional policies as needed using the guidance in Step 5 of this article.

To learn more about investigating communication compliance alerts, see Investigate and remediate communication compliance alerts.

Investigate and remediate communication compliance alerts

2/18/2021 • 11 minutes to read • Edit Online

After you've configured your communication compliance policies, you'll start to receive alerts in the Microsoft 365 compliance center for message issues that match your policy conditions. Follow the workflow instructions here to investigate and remediate alert issues.

Investigate alerts

The first step to investigate issues detected by your policies is to review communication compliance alerts in the Microsoft 365 compliance center. There are several areas in the communication compliance solution area to help you to quickly investigate alerts, depending on how you prefer to view alert grouping:

- **Communication compliance policy page**: When you sign in to https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization, select **Communication compliance** to display the communication compliance **Policy** page. This page displays communication compliance policies configured for your Microsoft 365 organization and links to recommended policy templates. Each policy listed includes the count of alerts that need review, the number of escalated and resolved items, status of the policy, and the date and time of the last policy scan. Selecting a policy displays all the pending alerts for matches to the policy, select a specific alert to launch the policy details page and to start remediation actions.
- **Alerts**: Navigate to **Communication compliance** > **Alerts** to display the last 30 days of alerts grouped by policy matches. This view allows you to quickly see which communication compliance policies are generating the most alerts ordered by severity. To start remediation actions, select the policy associated with the alert to launch the **Policy details** page. From the **Policy details** page, you can review a summary of the activities on the **Overview** page, review and act on alert messages on the **Pending** page, or review the history of closed alerts on the **Resolved** page.
- **Reports**: Navigate to **Communication compliance** > **Reports** to display communication compliance report widgets. Each widget provides an overview of communication compliance activities and statuses, including access to deeper insights about policy matches and remediation actions.

Using filters

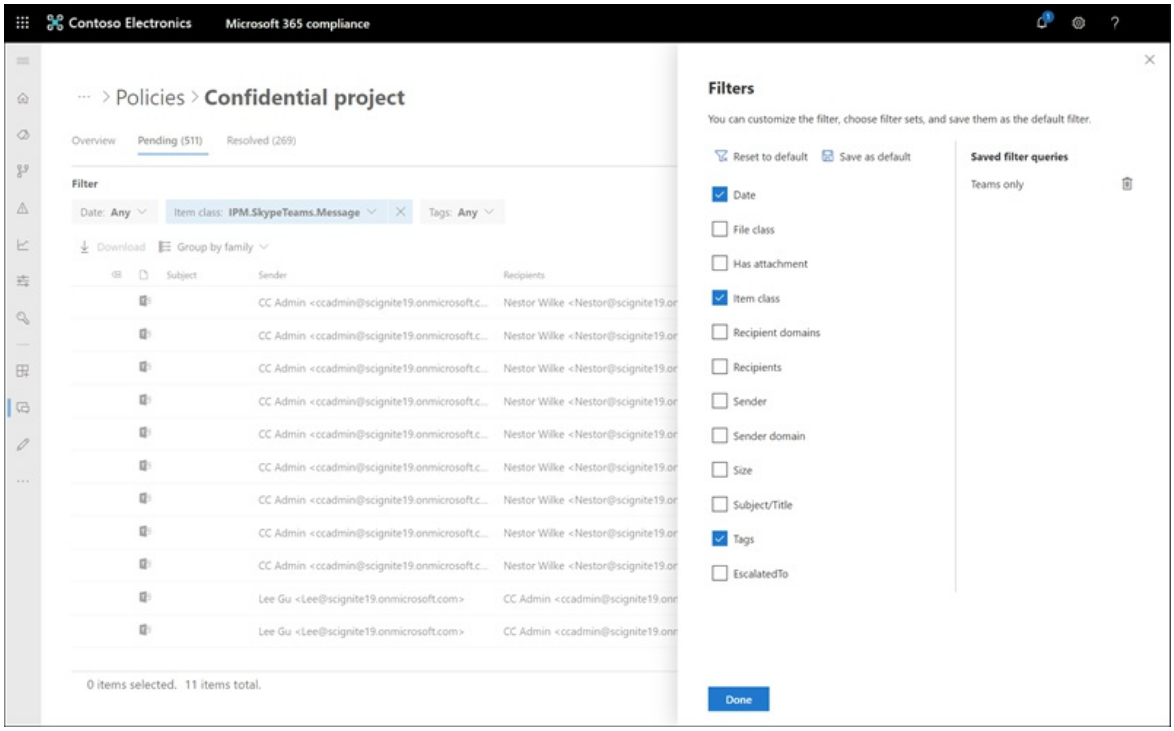
The next step is to sort the messages so that it's easier for you to investigate alerts. From the **Policy details** page, communication compliance supports multi-level filtering for several message fields to help you quickly investigate and review messages with policy matches. Filtering is available for pending and resolved items for each configured policy. You can configure filter queries for a policy or configure and save custom and default filter queries for use in each specific policy. After configuring fields for a filter, you'll see the filter fields displayed on the top of the alert message queue that you can configure for specific filter values.

For a complete list of filters and field details, see Filters in the feature reference article.

To configure a filter

1. Sign into https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization.
2. In the Microsoft 365 compliance center, go to **Communication compliance**.
3. Select the **Policies** tab and then select a policy for investigation, double-click to open the **Policy** page.
4. On the **Policy** page, select either the **Pending** or **Resolved** tab to display the items for filtering.

5. Select the **Filters** control to open the **Filters** details page.
6. Select one or more checkboxes to enable filters for these alerts. You can choose from numerous filters, including *Date*, *Sender*, *Subject/Title*, *Classifiers*, and more.
7. If you'd like to save the filter selected as the default filter, select **Save as default**. If you want to use this filter as a saved filter, select **Done**.
8. If you'd like to save the selected filters as a filter query, select **Save the query** control after you've configured at least one filter value. Enter a name for the filter query and select **Save**. This filter is available to use for only this policy and is listed in the **Saved filter queries** section of the **Filters** details page.

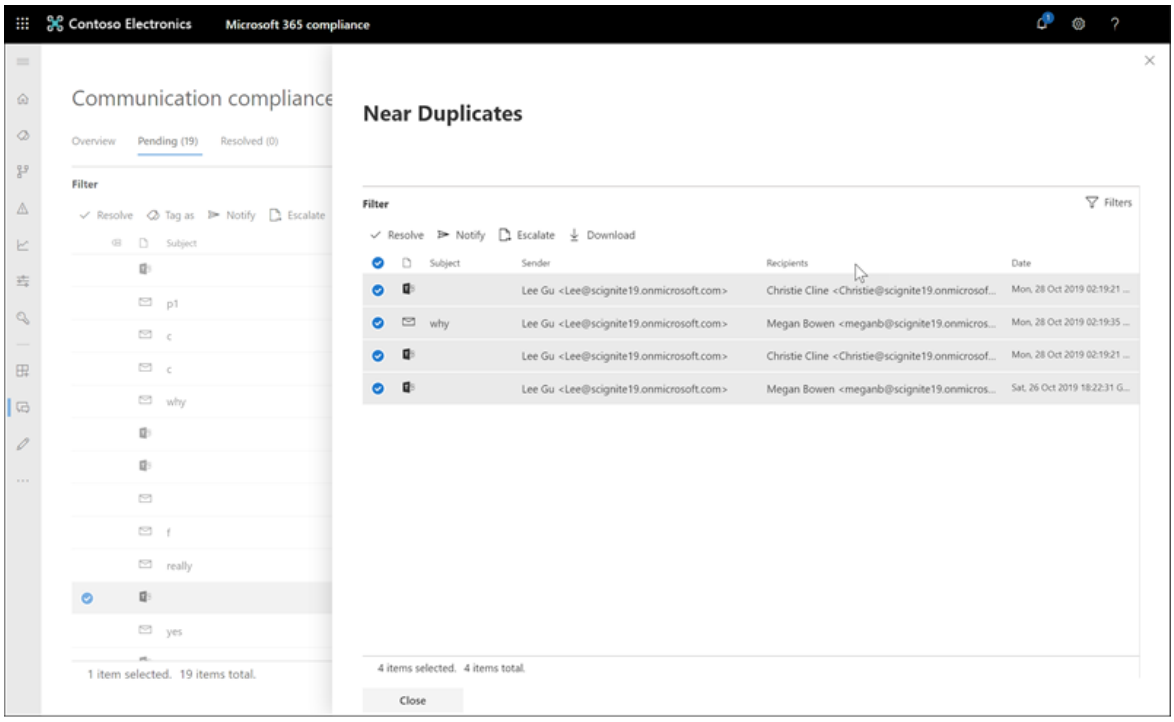


Using near and exact duplicate analysis

Communication compliance policies automatically scan and pre-group near and exact message duplicates without any additional configuration steps. This view allows you to quickly act on similar messages one-by-one or as a group, reducing the message investigation burden for reviewers. As duplicates are detected, the **Near Duplicates** and/or the **Exact Duplicates** controls are displayed in the remediation action toolbar. This view isn't available if near or exact duplicates aren't found.

To remediate duplicates

1. Sign into https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization.
2. In the Microsoft 365 compliance center, go to **Communication compliance**.
3. Select the **Policies** tab and then select a policy for investigation, double-click to open the **Policy** page.
4. On the **Policy** page, select either the **Pending** or **Resolved** tab to display duplicate messages.
5. Select the **Near Duplicates** or **Exact Duplicates** controls to open the duplicates details page.
6. Select one or more messages to remediation action controls for these messages.
7. Select **Resolve**, **Notify**, **Escalate**, or **Download** to apply the action to the selected duplicate messages as the default filter.
8. Select **Close** after completing the remediation actions on the messages.



Remediate alerts

No matter where you start to review alerts or the filtering you configure, the next step is to take action to remediate the alert. Start your alert remediation using the following workflow on the **Policy** or **Alerts** pages.

Step 1: Examine the message basics

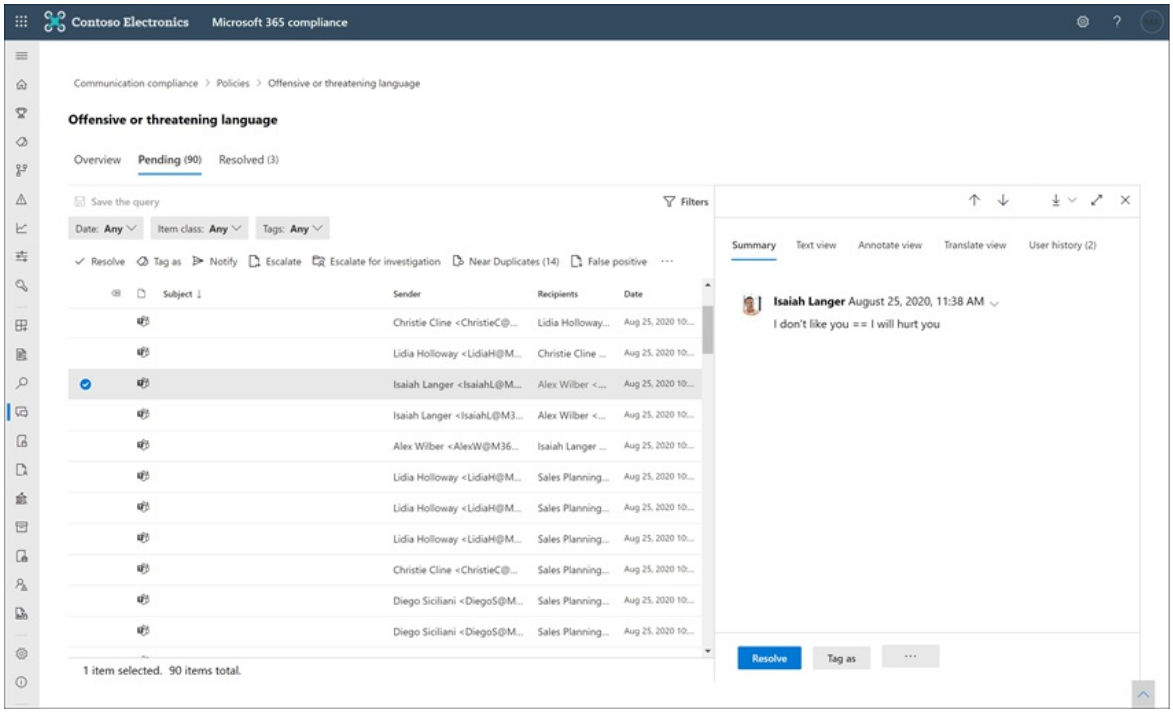
Sometimes it's obvious from the source or subject that a message can be immediately remediated. It may be that the message is spurious or incorrectly matched to a policy and it should be resolved as a false positive. Select the **False Positive** control to immediately resolve the alert and remove from the pending alert queue. From the source or sender information, you may already know how the message should be routed or handled in these circumstances. Consider using the **Tag as** or **Escalate** controls to assign a tag to applicable messages or to send messages to a designated reviewer.

Step 2: Examine the message details

After reviewing the message basics, it's time to open a message to examine the details and to determine further remediation actions. Select a message to view the complete message header and body information. Several different views are available to help you decide the proper course of action:

- **Source view**: This view is the standard message view commonly seen in most web-based messaging platforms. The header information is formatted in the normal style and the message body supports imbedded graphic files and word-wrapped text.
- **Text view**: Text view displays a line-numbered text-only view of the message and includes keyword highlighting in messages and attachments for terms matched in the associated communication compliance policy. Keyword highlighting can help you quickly scan long messages and attachments for the area of interest. In some cases, highlighted text may be only in attachments for messages matching policy conditions. Embedded files aren't displayed and the line numbering this view is helpful for referencing pertinent details among multiple reviewers.

- **Annotate view**: This view allows reviewers to add annotations directly on the message that are saved to the view of the message.
- **User history**: User history view displays all other alerts generated by any communication compliance policy for the user sending the message.
- **Message detail view**: Advanced view of message metadata and configuration information.
- **Pattern detected notification**: Many harassing and bullying actions over time and involve reoccurring instances of the same behavior by a user. The *Pattern detected* notification is displayed in the alert details and raises attention to the alert. Detection of patterns is on a per-policy basis and evaluates behavior over the last 30 days when at least two messages are sent to the same recipient by a sender. Investigators and reviewers can use this notification to identify repeated behavior to evaluate the alert as appropriate.
- **Show Translate view**: This view automatically converts alert message text to the language configured in the *Displayed language* setting in the Microsoft 365 subscription for each reviewer. The Translate view helps broaden investigative support for organizations with multilingual users and eliminates the need for additional translation services outside of the communication compliance review process. Using Microsoft Translate services, the Translate view can be turned on and off as needed and supports a wide range of languages. For a complete list of supported languages, see Microsoft Translator Languages. Languages listed in the *Translator Language List* are supported in the Translate view.



Step 3: Decide on a remediation action

Now that you've reviewed the details of the message for the alert, you can choose several remediation actions:

- **Resolve**: Selecting the **Resolve** control immediately removes the message from the **Pending alerts** queue and no further action can be taken on the message. By selecting **Resolve**, you've essentially closed the alert without further classification and it can't be reopened for further actions. All resolved messages are displayed in the **Resolved** tab.
- **False Positive**: You can always resolve a message as a false positive at any point during the message review workflow. False positive signifies that the alert was non-actionable or that the alert was incorrectly generated by the alerting process. The message cannot be reopened and all false positive messages are displayed in the **Resolved** tab.
- **Power Automate (preview)**: Use a Power Automate flow to automate process tasks for an alert message. By default, communication compliance includes the *Notify manager when a user has a*

communication compliance alert flow template that reviewers can use to automate the notification process for users with message alerts. For more information about creating and managing Power Automate flows in communication compliance, see the Communication compliance feature reference article.

- **Tag as**: Tag the message as *compliant*, *non-compliant*, or as *questionable* as it relates to the policies and standards for your organization. Adding tags and tagging comments helps you micro-filter policy alerts for escalations or as part of other internal review processes. After tagging is complete, you can also choose to resolve the message to move it out of the pending review queue.
- **Notify**: You can use the **Notify** control to assign a custom notice template to the alert and to send a warning notice to the user. Choose the appropriate notice template configured in the **Communication compliance settings** area and select **Send** to email a reminder to the user that sent the message and to resolve the issue.
- **Escalate**: Using the **Escalate** control, you can choose who else in your organization should review the message. Choose from a list of reviewers configured in the communication compliance policy to send an email notification requesting additional review of the message alert. The selected reviewer can use a link in the email notification to go directly to items escalated to them for review.
- **Escalate for investigation**: Using the **Escalate for investigation** control, you can create a new Advanced eDiscovery case for single or multiple messages. You'll provide a name and notes for the new case, and user who sent the message matching the policy is automatically assigned as the case custodian. You don't need any additional permissions to manage the case. Creating a case does not resolve or create a new tag for the message. You can select a total of 100 messages when creating an Advanced eDiscovery case during the remediation process. Messages in all communication channels monitored by communication compliance are supported. For example, you could select 50 Microsoft Teams chats, 25 Exchange Online email messages, and 25 Yammer messages when you open a new Advanced eDiscovery case for a user.
- **Improve classification (preview)**: Alerts created from classifier type matches may need feedback to help minimize false positives in your organization. Use the **Improve classification** control to provide feedback on if the communication compliance classification is valid or to suggest other trainable classifiers for this type of match. You can confirm that the classifiers are either a *Match* or *Not a match*, or suggest other trainable classifiers to associate with this type of alert activity in the future.

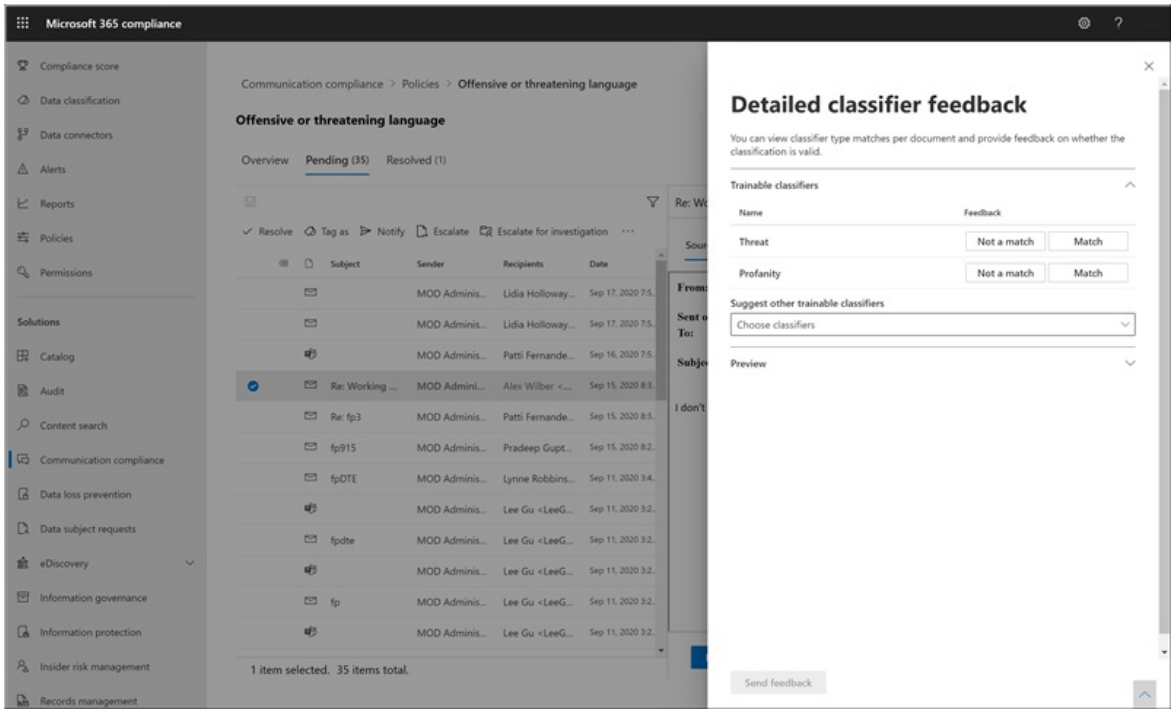
  1. Select a message from the alert list.
  2. Choose the ellipsis and select **Improve classification**.
  3. In the **Detailed classifier feedback** pane, if the item is a true positive, choose **Match**. If the item was incorrectly included in the category as a false positive, choose **Not a match**.
  4. If there is another classifier that would be more appropriate for the item, choose it from the **Suggest other trainable classifiers** list. This feedback triggers the other classifier to evaluate the item.

  > **TIP**
  > You can provide feedback on multiple items simultaneously by choosing them all and then choosing **Provide detailed feedback** in the command bar.

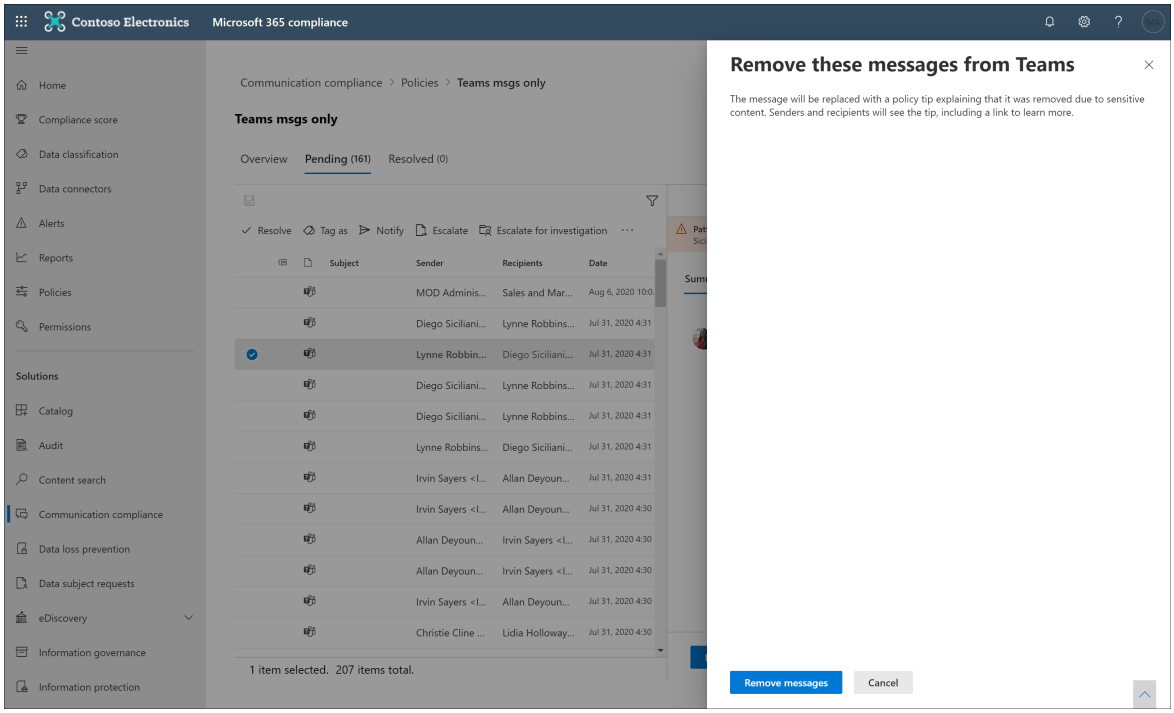
  5. Choose **Send feedback** to send your evaluation of the **Match** and **Not a match** classifications and suggest other trainable classifiers. When you've provided 30 instances of feedback to a classifier, it automatically retrains. Retraining may take 1-4 hours to complete. Classifiers can only be retrained twice per day.

> **IMPORTANT**
>
> This information goes to the classifier in your tenant, **it does not go back to Microsoft**.

To learn more about retraining classifier for communication compliance, see the How to retrain a classifier in communications compliance article.



- **Remove message in Teams**: Using the **Remove message in Teams** control, you can block inappropriate messages and content identified in alerts from Microsoft Teams channels and 1:1 and group chats. Removed messages and content are replaced with a policy tip that explains that it is blocked and the policy that applies to its removal from view. Recipients are provided a link in the policy tip to learn more about the applicable policy and the review process. The sender receives a policy tip for the blocked message and content but can review the details of the blocked message and content for context regarding the removal.



Step 4: Determine if message details should be archived outside of communication compliance

Message details can be exported or downloaded if you need to archive the messages in a separate storage solution. Selecting the **Download** control automatically adds selected messages to a .ZIP file that can be saved to storage outside of Microsoft 365.

Communication compliance feature reference

2/18/2021 • 38 minutes to read • Edit Online

Policies

> **IMPORTANT**
>
> Using PowerShell to create and manage communication compliance policies is not supported. To create and manage these policies, you must use the policy management controls in the Microsoft 365 communication compliance solution.

You create communication compliance policies for Microsoft 365 organizations in the Microsoft 365 compliance center. Communication compliance policies define which communications and users are subject to review in your organization, define which custom conditions the communications must meet, and specify who should do reviews. Users assigned the *Communication Compliance Admin* role can set up policies, and anyone who has this role assigned can access the **Communication compliance** page and global settings in the Microsoft 365 compliance center. If needed, you can export the history of modifications to a policy to a .csv file that also includes the status of alerts pending review, escalated items, and resolved items. Policies can't be renamed and can be deleted when no longer needed.

> **NOTE**
>
> Supervision policies created in the Security & Compliance Center for Office 365 subscriptions cannot migrate to Microsoft 365. If you're migrating from an Office 365 subscription to a Microsoft 365 subscription, you'll need to create new communication compliance polices to replace existing Supervision policies.

Policy templates

Policy templates are pre-defined policy settings that you can use to quickly create policies to address common compliance scenarios. Each of these templates has differences in conditions and scope, and all templates use the same types of scanning signals. You can choose from the following policy templates:

AREA	POLICY TEMPLATE	DETAILS
Offensive language and anti-harassment	Monitor communications for offensive language	- Locations: Exchange Online, Microsoft Teams, Yammer, Skype for Business - Direction: Inbound, Outbound, Internal - Review Percentage: 100% - Conditions: Offensive language classifier

AREA	POLICY TEMPLATE	DETAILS
Sensitive information	Monitor communications for sensitive information	- Locations: Exchange Online, Microsoft Teams, Yammer, Skype for Business - Direction: Inbound, Outbound, Internal - Review Percentage: 10% - Conditions: Sensitive information, out-of-the-box content patterns, and types, custom dictionary option, attachments larger than 1 MB
Regulatory compliance	Monitor communications for info related to financial regulatory compliance	- Locations: Exchange Online, Microsoft Teams, Yammer, Skype for Business - Direction: Inbound, Outbound - Review Percentage: 10% - Conditions: custom dictionary option, attachments larger than 1 MB
Conflict of interest	Monitor communications between two groups or two users to help avoid conflicts of interest	- Locations: Exchange Online, Microsoft Teams, Yammer, Skype for Business - Direction: Internal - Review Percentage: 100% - Conditions: None

Communications are scanned every 24 hours from the time policies are created. For example, if you create an offensive language policy at 11:00 AM, the policy will gather communication compliance signals every 24 hours at 11:00 AM daily. Editing a policy doesn't change this time. To view the last scan date and time for a policy, navigate to the *Last policy scan* column on the **Policy** page. After creating a new policy, it may take up to 24 hours to view the first policy scan date and time. The date and time of the last scan will be converted to the time zone of your local system.

Permissions

> **IMPORTANT**
> By default, Global Administrators do not have access to communication compliance features. The roles assigned in this step are required before any communication compliance features will be accessible.

There are five role groups used to configure permissions to manage communication compliance features. To make **Communication compliance** available as a menu option in Microsoft 365 compliance center and to continue with these configuration steps, you must be assigned to the *Communication Compliance* or *Communication Compliance Admin* role groups. To access and manage communication compliance features after initial configuration, users must be a member of at least one communication compliance role group.

Depending on how you wish to manage communication policies and alerts, you'll need to assign users to specific role groups. You have the option to assign users with different compliance responsibilities to specific role groups to manage different areas of communication compliance features. Or you may decide to assign all user accounts for designated administrators, analysts, investigators, and viewers to the *Communication Compliance* role group. Use a single role group or multiple role groups to best fit your compliance management requirements.

Choose from these role group options when configuring communication compliance:

ROLE GROUP	ROLE GROUP PERMISSIONS
Communication Compliance	Use this role group to manage communication compliance for your organization in a single group. By adding all user accounts for designated administrators, analysts, investigators, and viewers, you can configure communication compliance permissions in a single group. This role group contains all the communication compliance permission roles. This configuration is the easiest way to quickly get started with communication compliance and is a good fit for organizations that do not need separate permissions defined for separate groups of users.
Communication Compliance Admin	Use this role group to initially configure communication compliance and later to segregate communication compliance administrators into a defined group. Users assigned to this role group can create, read, update, and delete communication compliance policies, global settings, and role group assignments. Users assigned to this role group cannot view message alerts.
Communication Compliance Analyst	Use this group to assign permissions to users that will act as communication compliance analysts. Users assigned to this role group can view policies where they are assigned as Reviewers, view message metadata (not message content), escalate to other reviewers, or send notifications to users. Analysts cannot resolve pending alerts.
Communication Compliance Investigator	Use this group to assign permissions to users that will act as communication compliance investigators. Users assigned to this role group can view message metadata and content, escalate to other reviewers, escalate to an Advanced eDiscovery case, send notifications to users, and resolve the alert.
Communication Compliance Viewer	Use this group to assign permissions to users that will manage communication reports. Users assigned to this role group can access all reporting widgets on the communication compliance home page and can view all communication compliance reports.

For organizations using the original permissions and role groups

The new role group structure replaces initial role group structure for communication compliance. For organizations already using communication compliance, you needed to be assigned the Supervisory Review Administrator role to get started with communication compliance in the Microsoft 365 compliance center. Additionally, you had to create a new role group for reviewers with the Supervisory Review Administrator, Case Management, Compliance Administrator, and Review roles to investigate and remediate messages with policy matches. Essentially, all admins and reviewers were in a single role group and everyone had the same access and management permissions. With the latest updates to communication compliance, you should plan to migrate from the previous role group structure to the new role group structure. Support for the previous role group structure will be phased out.

To help your migration planning, consider the following example. You currently have three types of users in your organization, IT admins, triage, and reviewers. These three types of users are in the previous role group structure and are all members of a single role group with the following roles assigned:

- Supervisory Review Administrator
- Case Management

- Compliance Administrator
- Review

To update the roles for these users for the new role group structure, and to separate the access and management permissions for the users, you may consider three new groups and the associated new role group assignments:

- **IT Admins**: Assigned to the new *Communication Compliance Admin* role group.
- **Triage**: Assigned to the *Communication Compliance Analyst* role group.
- **Reviewers**: Assigned to the new *Communication Compliance Investigator* role group.

Supervised users

Before you start using communication compliance, you must determine who needs their communications reviewed. In the policy, user email addresses identify individuals or groups of people to supervise. Some examples of these groups are Microsoft 365 Groups, Exchange-based distribution lists, Yammer communities, and Microsoft Teams channels. You also can exclude specific users or groups from scanning with a specific exclusion group or a list of groups.

> **IMPORTANT**
> Users covered by communication compliance policies must have either a Microsoft 365 E5 Compliance license, an Office 365 Enterprise E3 license with the Advanced Compliance add-on, or be included in an Office 365 Enterprise E5 subscription. If you don't have an existing Enterprise E5 plan and want to try communication compliance, you can sign up for a trial of Office 365 Enterprise E5.

Reviewers

When you create a communication compliance policy, you must determine who reviews the messages of the supervised users. In the policy, user email addresses identify individuals or groups of people to review supervised communications. All reviewers must have mailboxes hosted on Exchange Online and must be assigned to either the *Communication Compliance Analysis* or *Communication Compliance Investigation* roles. Reviewers (either analysts or investigators) must also have the *Communication Compliance Case Management* role assigned. When reviewers are added to a policy, they automatically receive an email message that notifies them of the assignment to the policy and provides links to information about the review process.

Groups for supervised users and reviewers

To simplify your setup, create groups for people who need their communications reviewed and groups for people who review those communications. If you're using groups, you might need several. For example, if you want to scan communications between two distinct groups of people, or if you want to specify a group that isn't supervised.

When you assign a Distribution group in the policy, the policy monitors all emails from each user in Distribution group. When you assign a Microsoft 365 group in the policy, the policy monitors all emails sent to that group, not the individual emails received by each group member.

Adding groups and distribution lists to communication compliance policies are part of the overall conditions and rules set, so the maximum number of groups and distribution lists that a policy supports varies depending on the number of conditions also added to the policy. Each policy should support approximately 20 groups or distribution lists, depending on the number of additional conditions present in the policy.

Supported communication types

With communication compliance policies, you can choose to scan messages in one or more of the following communication platforms as a group or as standalone sources. Communications captured across these platforms are retained for seven years for each policy by default, even if users leave your organization and their mailboxes are deleted.

- **Microsoft Teams**: Chat communications in both public and private Microsoft Teams channels and individual chats can be scanned. When users are assigned to a communication compliance policy with Microsoft Teams coverage selected, chat communications for the users are automatically monitored across all Microsoft Teams where the users are a member. Microsoft Teams coverage is automatically included for pre-defined policy templates and is selected by default in the custom policy template. Teams chats matching communication compliance policy conditions may take up to 48 hours to process. Use the following group management configurations to supervise individual user chats and channel communications in Teams:
  - **For Teams chat communications:** Assign individual users or assign a distribution group to the communication compliance policy. This setting is for one-to-one or one-to-many user/chat relationships.
  - **For Teams Channel communications:** Assign every Microsoft Teams channel or Microsoft 365 group you want to scan that contains a specific user to the communication compliance policy. If you add the same user to other Microsoft Teams channels or Microsoft 365 groups, be sure to add these new channels and groups to the communication compliance policy.
  - **For Teams chat communications with hybrid email environments**: Communication compliance can monitor chat messages for users for organizations with an Exchange on-premises deployment or an external email provider that have enabled Microsoft Teams. You must create a distribution group for the users with on-premises or external mailboxes to monitor. When creating a communication compliance policy, you'll assign this distribution group as the **Supervised users and groups** selection in the policy wizard.

> **IMPORTANT**
> You must file a request with Microsoft Support to enable your organization to use the graphical user interface in the Security & Compliance Center to search for Teams chat data for on-premises users. For more information, see Searching cloud-based mailboxes for on-premises users.

You must file a request with Microsoft Support to enable your organization to use the graphical user interface in the Security & Compliance Center to search for Teams chat data in the cloud-based mailboxes for on-premises users.

- **Exchange email**: Mailboxes hosted on Exchange Online as part of your Microsoft 365 or Office 365 subscription are all eligible for message scanning. Exchange email messages and attachments matching communication compliance policy conditions may take up to 24 hours to process. Supported attachment types for communication compliance are the same as the file types supported for Exchange mail flow rule content inspections.
- **Yammer**: Private messages and public conversations and associated attachments in Yammer communities can be scanned. When a user is added to communication compliance policy that includes Yammer as a defined channel, communications across all Yammer communities that the user is a member of are included in the scanning process. Yammer chats and attachments matching communication compliance policy conditions may take up to 24 hours to process. Yammer must be in Native Mode for communication compliance policies to monitor Yammer communications and attachments. In Native Mode, all Yammer users are in Azure Active Directory (AAD), all groups are Office 365 Groups, and all files are stored in SharePoint Online.
- **Skype for Business Online**: Chat communications and associated attachments in Skype for Business

Online can be supervised. Skype for Business Online chats matching communication compliance policy conditions may take up to 24 hours to process. Supervised chat conversations are sourced from previous conversations saved in Skype for Business Online. Use the following group management configuration to supervise user chat communications in Skype for Business Online:

  - **For Skype for Business Online chat communications**: Assign individual users or assign a distribution group to the communication compliance policy. This setting is for one-to-one or one-to-many user/chat relationships.

- **Third-party sources**: You can scan communications for data imported into mailboxes in your Microsoft 365 organization from third-party sources like Instant Bloomberg, Slack, Zoom, SMS, and many others. For a full list of connectors supported in communication compliance, see Archive third-party data.

  You must configure a third-party connector for your Microsoft 365 organization before you can assign the connector to a communication compliance policy. The **Third-Party Sources** section of the communication compliance policy wizard only displays currently configured third-party connectors.

Transitioning from Supervision in Office 365

Organizations using supervision policies in Office 365 and planning to transition to communication compliance policies in Microsoft 365 need to understand these important points:

- Both solutions may be used side by side in your organization, but policies used in each solution must have unique policy names. Groups and custom keyword dictionaries can be shared between solutions during a transition period.
- Messages saved in supervision in Office 365 policy matches cannot be moved or shared into communication compliance in Microsoft 365.
- The supervision solution in Office 365 will be fully replaced by the communication compliance solution in Microsoft 365. We recommend creating new policies in communication compliance that have the same settings as existing supervision policies to use the new investigation and remediation improvements. When transitioning to communication compliance in Microsoft 365, you should plan to export reporting data from supervision in Office 365 if you have internal compliance retention policy requirements.

For retirement information for supervision in Office 365, see the Microsoft 365 Roadmap for details.

Policy settings

Users

You have the option to select **All users** or to define specific users in a communication compliance policy. Selecting **All users** applies the policy to all users and all groups that any user is included in as a member. Defining specific users applies the policy to the defined users and any groups the defined users are included in as a member.

Direction

By default, the **Direction is** condition is displayed and can't be removed. Communication direction settings in a policy are chosen individually or together:

- **Inbound**: You can choose **Inbound** to review communications sent **to** the people you chose to supervise.
- **Outbound**: You can choose **Outbound** if you want to review communications sent **from** the people you chose to supervise.
- **Internal**: You can choose **Internal** to review communications sent **between** the people you identified in the policy.

Sensitive information types

You have the option of including sensitive information types as part of your communication compliance policy.

Sensitive information types are either pre-defined or custom data types that can help identify and protect credit card numbers, bank account numbers, passport numbers, and more. As part of data loss prevention (DLP), the sensitive information configuration can use patterns, character proximity, confidence levels, and even custom data types to help identify and flag content that may be sensitive. The default sensitive information types are:

- Financial
- Medical and health
- Privacy
- Custom information type

To learn more about sensitive information details and the patterns included in the default types, see Sensitive information type entity definitions.

Custom keyword dictionaries

Configure custom keyword dictionaries (or lexicons) to provide simple management of keywords specific to your organization or industry. Keyword dictionaries support up to 100 KB of terms (post-compression) in the dictionary and support any language. The tenant limit is also 100 KB after compression. If needed, you can apply multiple custom keyword dictionaries to a single policy or have a single keyword dictionary per policy. These dictionaries are assigned in a communication compliance policy and can be sourced from a file (such as a .csv or .txt list), or from a list you can Import in the Compliance center. Use custom dictionaries when you need to support terms or languages specific to your organization and policies.

Classifiers

Built-in trainable and global classifiers scan sent or received messages across all communication channels in your organization for different types of compliance issues. Classifiers use a combination of artificial intelligence and keywords to identify language in messages likely to violate anti-harassment policies. Built-in classifiers currently support only English keywords in messages.

Communication compliance built-in trainable and global classifiers scan communications for terms, images, and sentiment for the following types of language and content:

- **Threat**: Scans for threats to commit violence or physical harm to a person or property.
- **Targeted harassment**: Scans for offensive conduct targeting people regarding race, color, religion, national origin.
- **Profanity**: Scans for profane expressions that embarrass most people.
- **Adult images**: Scans for images that are sexually explicit in nature.
- **Racy images**: Scans for images that are sexually suggestive in nature, but contain less explicit content than images deemed Adult.
- **Gory images**: Scans for images that depict violence and gore.

The *Adult*, *Racy*, and *Gory* image classifiers scan files in .JPEG, .PNG, .GIF, and .BMP formats. The size for image files must be less than 4 megabytes (MB) and the dimensions of the images must be greater than 50x50 pixels and greater than 50 kilobytes (KB) for the image to qualify for evaluation. Image identification is supported for Exchange Online email messages and Microsoft Teams channels and chats.

The built-in trainable and global classifiers don't provide an exhaustive list of terms or images across these areas. Further, language and cultural standards continually change, and in light of these realities, Microsoft reserves the right to update classifiers at its discretion. While classifiers may assist your organization in monitoring these areas, classifiers aren't intended to provide your organization's sole means of monitoring or addressing such language or imagery. Your organization, not Microsoft, remains responsible for all decisions related to monitoring, scanning, and blocking language and images in these areas, including compliance with local privacy and other applicable laws. Microsoft encourages consulting with legal counsel before deployment and use.

NOTE

Policies using classifiers will inspect and evaluate messages with a word count of six or greater. Messages containing less than six words aren't evaluated in policies using classifiers. To identify and take action on shorter messages containing inappropriate content, we recommend including a custom keyword dictionary to communication compliance policies monitoring for this type of content.

For information about trainable classifiers in Microsoft 365, see Getting started with trainable classifiers.

Conditional settings

The conditions you choose for the policy apply to communications from both email and third-party sources in your organization (like from Instant Bloomberg).

The following table explains more about each condition.

CONDITION	HOW TO USE THIS CONDITION
Content matches any of these classifiers	Apply to the policy when any classifiers are included or excluded in a message. Some classifiers are pre-defined in your tenant, and custom classifiers must be configured separately before they're available for this condition. Only one classifier can be defined as a condition in a policy. For more information about configuring classifiers, see Learn about trainable classifiers (preview).
Content contains any of these sensitive info types	Apply to the policy when any sensitive information types are included or excluded in a message. Some classifiers are pre-defined in your tenant, and custom classifiers can be configured separately or as part of the condition assignment process. Each sensitive information type you choose is applied separately and only one of these sensitive information types must apply for the policy to apply to the message. For more information about custom sensitive information types, see Learn about sensitive information types.
Message is received from any of these domains **Message is not received from any of these domains**	Apply the policy to include or exclude specific domains or email addresses in received messages. Enter each domain or email address and separate multiple domains or email addresses with a comma. Each domain or email address entered is applied separately, only one domain or email address must apply for the policy to apply to the message. If you want to scan all email from a specific domain, but want to exclude messages that don't need review (newsletters, announcements, and so on), you must configure a **Message is not received from any of these domains** condition that excludes the email address (example "newsletter@contoso.com").

CONDITION	HOW TO USE THIS CONDITION
Message is sent to any of these domains **Message is not sent to any of these domains**	Apply the policy to include or exclude specific domains or email addresses in sent messages. Enter each domain or email address and separate multiple domains or email addresses with a comma. Each domain or email address is applied separately, only one domain or email address must apply for the policy to apply to the message. If you want to scan all email sent to a specific domain, but want to exclude sent messages that don't need review, you must configure two conditions: - A **Message is sent to any of these domains** condition that defines the domain ("contoso.com"), AND - A **Message is not sent to any of these domains** condition that excludes the email address ("subscriptions@contoso.com").
Message is classified with any of these labels **Message is not classified with any of these labels**	To apply the policy when certain retention labels are included or excluded in a message. Retention labels must be configured separately and configured labels are chosen as part of this condition. Each label you choose is applied separately (only one of these labels must apply for the policy to apply to the message). For more information about retention labels, see Learn about retention policies and retention labels.
Message contains any of these words **Message contains none of these words**	To apply the policy when certain words or phrases are included or excluded in a message, enter each word separated with a comma. For phrases of two words or more, use quotation marks around the phrase. Each word or phrase you enter is applied separately (only one word must apply for the policy to apply to the message). For more information about entering words or phrases, see the next section Matching words and phrases to emails or attachments.
Attachment contains any of these words **Attachment contains none of these words**	To apply the policy when certain words or phrases are included or excluded in a message attachment (such as a Word document), enter each word separated with a comma. For phrases of two words or more, use quotation marks around the phrase. Each word or phrase you enter is applied separately (only one word must apply for the policy to apply to the attachment). For more information about entering words or phrases, see the next section Matching words and phrases to emails or attachments.
Attachment is any of these file types **Attachment is none of these file types**	To supervise communications that include or exclude specific types of attachments, enter the file extensions (such as .exe or .pdf). If you want to include or exclude multiple file extensions, enter these on separate lines. Only one attachment extension must match for the policy to apply.
Message size is larger than **Message size is not larger than**	To review messages based on a certain size, use these conditions to specify the maximum or minimum size a message can be before it's subject to review. For example, if you specify **Message size is larger than** > **1.0 MB**, all messages that are 1.01 MB and larger are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.

CONDITION	HOW TO USE THIS CONDITION
Attachment is larger than **Attachment is not larger than**	To review messages based on the size of their attachments, specify the maximum or minimum size an attachment can be before the message and its attachments are subject to review. For example, if you specify **Attachment is larger than** > **2.0 MB**, all messages with attachments 2.01 MB and over are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.

Matching words and phrases to emails or attachments

Each word you enter and separate with a comma is applied separately (only one word must apply for the policy condition to apply to the email or attachment). For example, let's use the condition, **Message contains any of these words**, with the keywords "banker", "confidential", and "insider trading" separated by a comma (banker, confidential,"insider trading"). The policy applies to any messages that includes the word "banker", "confidential", or the phrase "insider trading". Only one of these words or phrases must occur for this policy condition to apply. Words in the message or attachment must exactly match what you enter.

> **IMPORTANT**
> When importing a custom dictionary file, each word or phrase must be separated with a carriage return and on a separate line.
> For example:
>
> *banker*
> *confidential*
> *insider trading*

To scan both email messages and attachments for the same keywords, create a data loss prevention policy with a custom keyword dictionary for the terms you wish to scan in messages. This policy configuration identifies defined keywords that appear in either the email message **OR** in the email attachment. Using the standard conditional policy settings (*Message contains any of these words* and *Attachment contains any of these words*) to identify terms in messages and in attachments requires the terms to be present in **BOTH** the message and the attachment.

Enter multiple conditions

If you enter multiple conditions, Microsoft 365 uses all the conditions together to determine when to apply the communication compliance policy to communication items. When you set up multiple conditions, all conditions must be met for the policy to apply, unless you enter an exception. For example, you need a policy that applies if a message contains the word "trade", and is larger than 2 MB. However, if the message also contains the words "Approved by Contoso financial", the policy shouldn't apply. In this example, the three conditions would be defined as follows:

- **Message contains any of these words**, with the keyword "trade"
- **Message size is larger than**, with the value 2 MB
- **Message contains none of these words**, with the keywords "Approved by Contoso financial team"

Review percentage

If you want to reduce the amount of content to review, you can specify a percentage of all the communications governed by a communication compliance policy. A real-time, random sample of content is selected from the total percentage of content that matches chosen policy conditions. If you want reviewers to review all items, you can configure **100%** in a communication compliance policy.

Privacy

Protecting the privacy of users that have policy matches is important and can help promote objectivity in data investigation and analysis reviews for communication compliance alerts. This setting applies only to user names displayed the communication compliance solution. It does not affect how names are displayed in other compliance solutions or admin center.

For users with a communication compliance match, you can choose one of the following settings in **Communication compliance settings**:

- **Show anonymized versions of usernames**: User names are anonymized to prevent users in *Communication Compliance Analyst* role group from seeing who is associated with policy alerts. Users in the *Communication Compliance Investigator* role group will always see user names, not the anonymized versions. For example, a user 'Grace Taylor' would appear with a randomized pseudonym such as 'AnonIS8-988' in all areas of the communication compliance experience. Choosing this setting anonymizes all users with current and past policy matches and applies to all policies. User profile information in the communication compliance alert details will not be available when this option is chosen. However, user names are displayed when adding new users to existing policies or when assigning users to new policies. If you choose to turn off this setting, user names are displayed for all users that have current or past policy matches.
- **Do not show anonymized versions of usernames**: User names are displayed for all current and past policy matches for communication compliance alerts. User profile information (the name, title, alias, and organization or department) is displayed for the user for all communication compliance alerts.

Notice templates

You can create notice templates if you want to send users an email reminder notice for policy matches as part of the issue resolution process. Notices can only be sent to the user email address associated with the policy match that generated the specific alert for remediation. When selecting a notice template to apply to a policy violation as part of the remediation workflow, you can choose to accept the field values defined in the template or overwrite the fields as needed.

Notices templates are custom email templates where you can define the following message fields in the **Communication compliance settings** area:

FIELD	REQUIRED	DETAILS
Template name	Yes	Friendly name for the notice template that you'll select in the notify workflow during remediation, supports text characters.
Sender address	Yes	The address of one or more users or groups that send the message to the user with a policy match, selected from the Active Directory for your subscription.
CC and BCC addresses	No	Optional users or groups to be notified of the policy match, selected from the Active Directory for your subscription.
Subject	Yes	Information that appears in the subject line of the message, supports text characters.

FIELD	REQUIRED	DETAILS
Message body	Yes	Information that appears in the message body, supports text or HTML values.

HTML for notices

If you'd like to create more than a simple text-based email message for notifications, you can create a more detailed message by using HTML in the message body field of a notice template. The following example provides the message body format for a basic HTML-based email notification template:

```
<!DOCTYPE html>
<html>
    <body>
        <h2>Action Required: Contoso Employee Code of Conduct Policy Training</h2>
        <p>A recent message you've sent has generated a policy alert for the Contoso Employee <a
href='https://www.contoso.com'>Code of Conduct Policy</a>.</p>
        <p>You are required to attend the Contoso Employee Code of Conduct <a
href='https://www.contoso.com'>training</a> within the next 14 days. Please contact <a
href='mailto:hr@contoso.com'>Human Resources</a> with any questions about this training request.</p>
        <p>Thank you,</p>
        <p><em>Human Resources</em></p>
    </body>
</html>
```

> **NOTE**
> HTML href attribute implementation in the communication compliance notification templates currently support only single quotation marks instead of double quotation marks for URL references.

Filters

Communication compliance filters allow you to filter and sort alert messages for quicker investigation and remediation actions. Filtering is available on the **Pending** and **Resolved** tabs for each policy. To save a filter or filter set as a saved filter query, one or more values must be configured as filter selections. The following table outlines filter details:

FILTER	DETAILS
Date	The date the message was sent or received by a user in your organization. To filter for a single day, select a date range that starts with the day you want results for and end with the following day. For example, if you wanted to filter results for 9/20/2020, you would choose a filter date range of 9/20/2020-9/21/2020.
File class	The class of the message based on the message type, either *message* or *attachment*.
Has attachment	The attachment presence in the message.
Item class	The source of the message based on the message type, email, Microsoft Team chat, Bloomberg, etc. For more information on common Item Types and Message Classes, see Item Types and Message Classes.

FILTER	DETAILS
Recipient domains	The domain to which the message was sent. This domain is normally your Microsoft 365 subscription domain by default.
Recipient	The user to which the message was sent.
Sender	The person who sent the message.
Sender domain	The domain that sent the message.
Size	The size of the message in KB.
Subject/Title	The message subject or chat title.
Tags	The tags assigned to a message, either *Questionable*, *Compliant*, or *Non-compliant*.
Escalated To	The user name of the person included as part of a message escalation action.
Classifiers	The name of built-in and custom classifiers that apply to the message. Some examples include *Offensive Language*, *Targeted Harassment*, *Profanity*, *Threat*, and more.

Alert policies

After you configure a policy, a corresponding alert policy is automatically created and alerts are generated for messages that match conditions defined in the policy. By default, all policy matches alert triggers are assigned a severity level of medium in the associated alert policy. Alerts are generated for a communication compliance policy once the aggregation trigger threshold level is met in the associated alert policy.

For communication compliance policies, the following alert policy values are configured by default:

ALERT POLICY TRIGGER	DEFAULT VALUE
Aggregation	Simple aggregation
Threshold	4 activities
Window	60 minutes

> **NOTE**
> The alert policy threshold trigger settings for activities supports a minimum value of 3 or higher for communication compliance policies.

You can change the default settings for triggers on number of activities, period for the activities, and for specific users in alert policies on the **Alert policies** page in the Security & Compliance Center.

Change the severity level for an alert policy

If you'd like to change the severity level assigned in an alert policy for a specific communication compliance policy, complete the following steps:

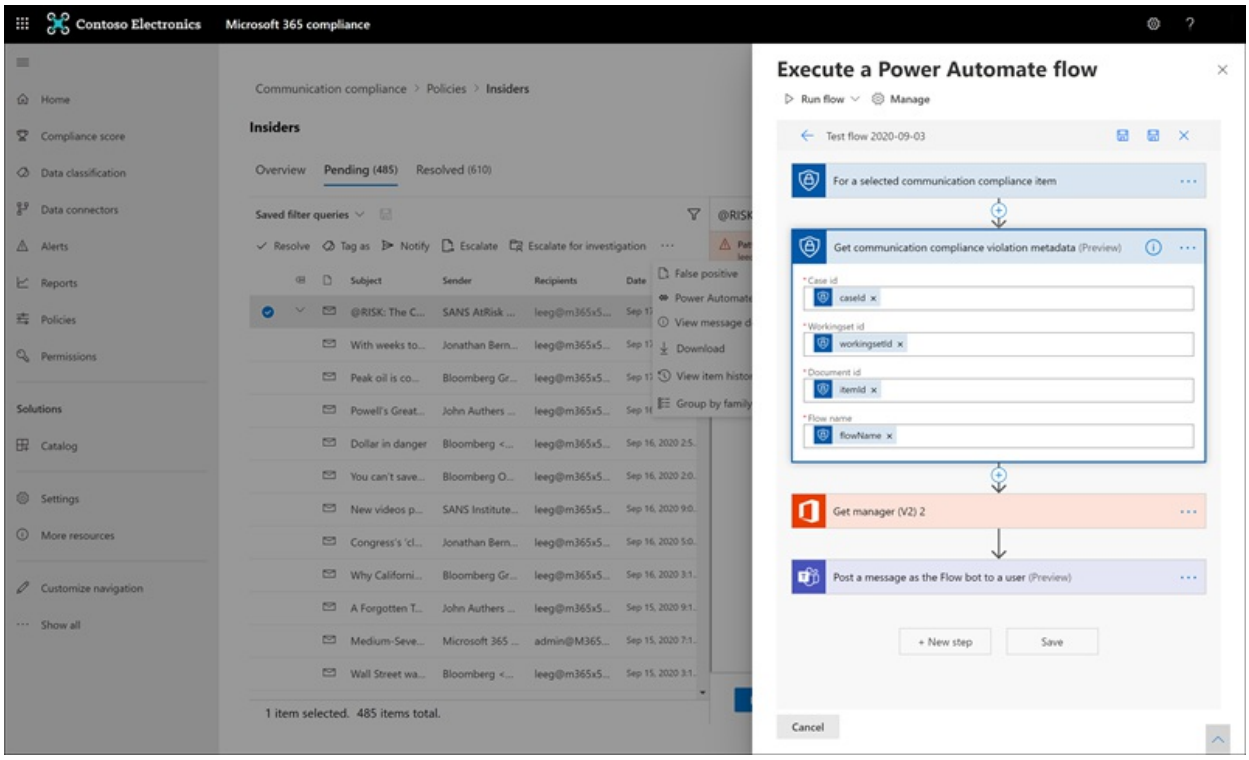
1. Sign into https://compliance.microsoft.com using credentials for an admin account in your Microsoft 365 organization.
2. In the Microsoft 365 compliance center, go to **Policies**.
3. Select **Office 365 alert** on the **Policies** page to open the **Alerts policies** page in the **Office 365 Security & Compliance center**.
4. Select the checkbox for the communication compliance policy you want to update, then select **Edit policy**.
5. On the **Description** tab, select the **Severity** dropdown to configure the policy alert level.
6. Select **Save** to apply the new severity level to the policy.
7. Select **Close** to exit the alert policy details page.

Power Automate flows

Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or created manually, you can automate common tasks associated with these applications and services. When you enable Power Automate flows for communication compliance, you can automate important tasks for alerts and users. You can configure Power Automate flows to notify managers when users have communication compliance alerts and other applications.

Customers with Microsoft 365 subscriptions that include communication compliance do not need additional Power Automate licenses to use the recommended default communication compliance Power Automate template. The default template can be customized to support your organization and cover core communication compliance scenarios. If you choose to use premium Power Automate features in these templates, create a custom template using the Microsoft 365 compliance connector, or use Power Automate templates for other compliance areas in Microsoft 365, you may need additional Power Automate licenses.

> **IMPORTANT**
>
> Are you receiving prompts for additional license validation when testing Power Automate flows? Your organization may not have received service updates for this preview feature yet. Updates are being deployed and all organizations with Microsoft 365 subscriptions that include communication compliance should have license support for flows created from the recommended Power Automate templates by October 30, 2020.



The following Power Automate template is provided to customers to support process automation for communication compliance alerts:

- **Notify manager when a user has a communication compliance alert**: Some organizations may need to have immediate management notification when a user has a communication compliance alert. When this flow is configured and selected, the manager for the case user is sent an email message with the following information about all alerts:
  - Applicable policy for the alert
  - Date/Time of the alert
  - Severity level of the alert

Create a Power Automate flow

To create a Power Automate flow from a recommended default template, you'll use the **Manage Power Automate flows** option from the **Automate** control when working directly in an alert. To create a Power Automate flow with **Manage Power Automate flows**, you must be a member of at least one communication compliance role group.

Complete the following steps to create a Power Automate flow from a default template:

1. In the Microsoft 365 compliance center, go to **Communication compliance** > **Policies** and select the policy with the alert you want review.
2. From the policy, select the **Pending** tab and select a pending alert.
3. Select **Power Automate** from the alert action menu.
4. On the **Power Automate** page, select a default template from the **Communication compliance templates you may like** section on the page.
5. The flow will list the embedded connections needed for the flow and will display if the connection statuses are available. If needed, update any connections that aren't displayed as available. Select **Continue**.
6. By default, the recommended flows are pre-configured with the recommended communication compliance and Microsoft 365 service data fields required to complete the assigned task for the flow. If needed, customize the flow components by using the **Show advanced options** control and configuring the available properties for the flow component.
7. If needed, add any additional steps to the flow by selecting the **New step** button. In most cases, this change should not be needed for the recommended default templates.

8. Select **Save draft** to save the flow for further configuration later, or select **Save** to complete the configuration for the flow.
9. Select **Close** to return to the Power Automate flow page. The new template will be listed as a flow on the **My flows** tab and is automatically available from the Power Automate control for the user that created the flow when working with communication compliance alerts.

Share a Power Automate flow

By default, Power Automate flows created by a user are only available to that user. For other communication compliance users to have access and use a flow, the flow must be shared by the flow creator. To share a flow, you'll use the **Power Automate** control when working directly in an alert.

To share a Power Automate flow, you must be a member of at least one communication compliance role group. Complete the following steps to share a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Communication compliance** > **Policies** and select the policy with the alert you want review.
2. From the policy, select the **Pending** tab and select a pending alert.
3. Select **Power Automate** from the alert action menu.
4. On the **Power Automate flows** page, select the **My flows** or **Team flows** tab.
5. Select the flow to share, then select **Share** from the flow options menu.
6. On the flow sharing page, enter the name of the user or group you want to add as an owner for the flow.
7. On the **Connection Used** dialog, select **OK** to acknowledge that the added user or group will have full access to the flow.

Edit a Power Automate flow

If you need to edit a flow, you'll use the **Power Automate** control when working directly in an alert. To edit a Power Automate flow, you must be a member of at least one communication compliance role group.

Complete the following steps to edit a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Communication compliance** > **Policies** and select the policy with the alert you want review.
2. From the policy, select the **Pending** tab and select a pending alert.
3. Select **Power Automate** from the alert action menu.
4. On the **Power Automate flows** page, select flow to edit. Select **Edit** from the flow control menu.
5. Select the **ellipsis** > **Settings** to change a flow component setting or **ellipsis** > **Delete** to delete a flow component.
6. Select **Save** and then **Close** to complete editing the flow.

Delete a Power Automate flow

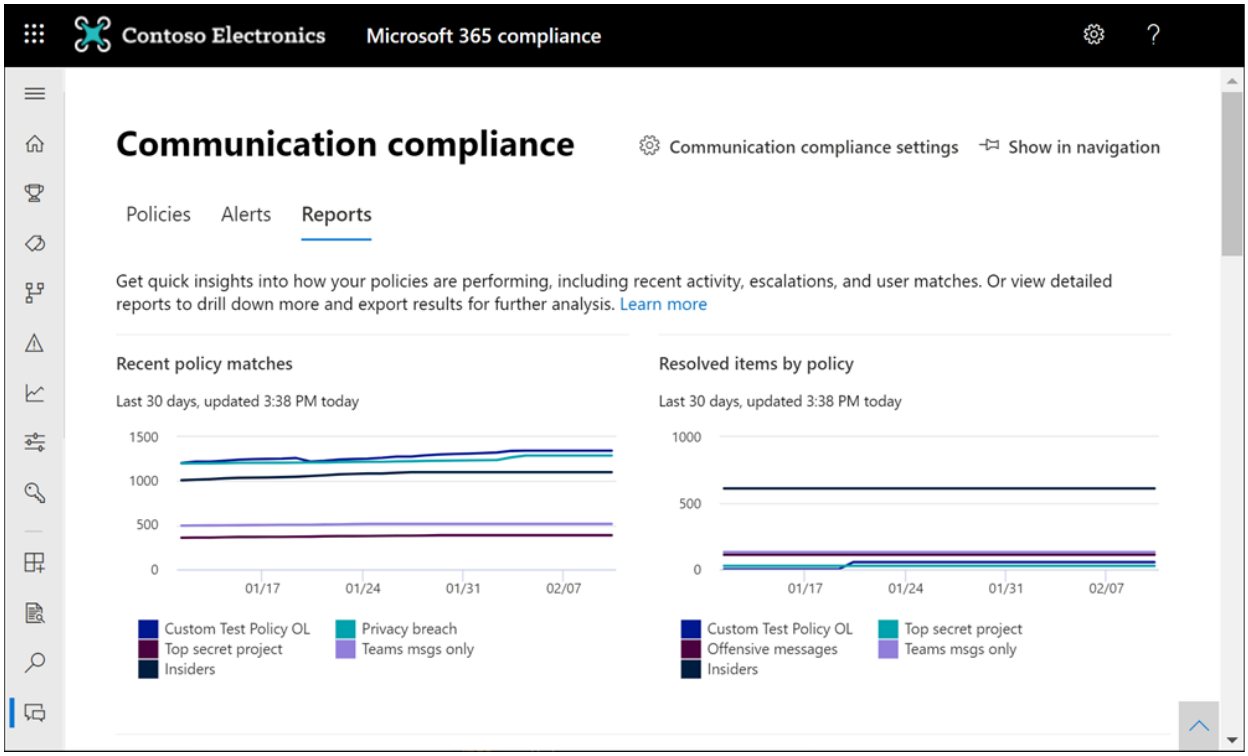
If you need to delete a flow, you'll use the **Power Automate** control when working directly in an alert. To delete a Power Automate flow, you must be a member of at least one communication compliance role group.

Complete the following steps to delete a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Communication compliance** > **Policies** and select the policy with the alert you want review.
2. From the policy, select the **Pending** tab and select a pending alert.
3. Select **Power Automate** from the alert action menu.
4. On the **Power Automate flows** page, select flow to delete. Select **Delete** from the flow control menu.
5. On the deletion confirmation dialog, select **Delete** to remove the flow or select **Cancel** to exit the deletion action.

Reports (preview)

The new **Reports** dashboard is the central location for viewing all communication compliance reports. Report widgets provide a quick view of insights most commonly needed for an overall assessment of the status of communication compliance activities. Information contained in the report widgets is not exportable. Detailed reports provide in-depth information related to specific communication compliance areas and offer the ability to filter, group, sort, and export information while reviewing.



The **Reports dashboard** contains the following report widgets and detailed reports links:

- **Recent policy matches** widget: displays the number of matches by active policy over time.
- **Resolved items by policy** widget: displays the number of policy match alerts resolved by policy over time.
- **Users with most policy match** widget: displays the users (or anonymized usernames) and number of policy matches for a given period.
- **Policy with most matches** widget: displays the policies and the number of matches for a given period, ranked highest to lowest for matches.
- **Escalations by policy** widget: displays the number of escalations per policy over a given time.
- **Policy settings and status** detailed report: provides a detailed look at policy configuration and settings, as well as the general status for each of the policy (matches and actions) on messages. Includes policy information and how policies are associated with users and groups, locations, review percentages, reviewers, status, and when the policy was last modified. Use the *Export* option to create a .CSV file containing the report details.
- **Items and actions per policy** detailed report: Review and export matching items and remediation actions per policy. Includes policy information and how policies are associated with:
  - Items matched
  - Escalated items
  - Resolved items
  - Tagged as compliant

- Tagged as non-compliant
- Tagged as questionable
- Items pending review
- User notified
- Case created

Use the *Export* option to create a .csv file containing the report details.

- **Item and actions per location** detailed report: Review and export matching items and remediation actions per Microsoft 365 location. Includes information about how workload platforms are associated with:

  - Items matched
  - Escalated items
  - Resolved items
  - Tagged as compliant
  - Tagged as non-compliant
  - Tagged as questionable
  - Items pending review
  - User notified
  - Case created

  Use the *Export* option to create a .csv file containing the report details.

- **Activity by user** detailed report: Review and export matching items and remediation actions per user. Includes information about how users are associated with:

  - Items matched
  - Escalated items
  - Resolved items
  - Tagged as compliant
  - Tagged as non-compliant
  - Tagged as questionable
  - Items pending review
  - User notified
  - Case created

  Use the *Export* option to create a .csv file containing the report details.

Audit

In some instances, you must provide information to regulatory or compliance auditors to prove supervision of user activities and communications. This information may be a summary of all activities associated with a defined organizational policy or anytime a communication compliance policy changes. Communication compliance policies have built-in audit trails for complete readiness for internal or external audits. Detailed audit histories of every create, edit, and delete action are captured by your communication policies to provide proof of supervisory procedures.

> **IMPORTANT**
> Auditing must be enabled for your organization before communication compliance events will be recorded. To enable auditing, see Enable the audit log.

To view communication compliance policy update activities, select the **Export policy updates** control on the

main page for any policy. You must be assigned the *Global Admin* or *Communication Compliance Admin* roles to export update activities. This action generates an audit file in the .csv format that contains the following information:

FIELD	DETAILS
CreationDate	The date the update activity was performed in a policy.
UserIds	The user that performed the update activity in a policy.
Operations	The update operations performed on the policy.
AuditData	This field is the main data source for all policy update activities. All update activities are recorded and separated by comma delimiters.

To view communication compliance review activities for a policy, select the **Export review activities** control on the **Overview** page for a specific policy. You must be assigned the *Global Admin* or *Communication Compliance Admin* roles to export review activities. This action generates an audit file in the .csv format that contains the following information:

FIELD	DETAILS
CreationDate	The date the review activity was performed in a policy.
UserIds	The user that performed the review activity in a policy.
Operations	The review operations performed on the policy.
AuditData	This field is the main data source for all policy review activities. All review activities are recorded and separated by comma delimiters.

You can also view audit activities in the unified audit log or with the Search-UnifiedAuditLog PowerShell cmdlet.

For example, the following example returns the activities for all the supervisory review activities (policies and rules):

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -RecordType AeD -Operations
SupervisoryReviewTag
```

This example returns the update activities for your communication compliance policies:

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -RecordType Discovery -Operations
SupervisionPolicyCreated,SupervisionPolicyUpdated,SupervisionPolicyDeleted
```

To configure communication compliance for your Microsoft 365 organization, see Configure communication compliance for your Microsoft 365 organization.

Case study - Contoso quickly configures an offensive language policy for Microsoft Teams, Exchange, and Yammer communications

2/18/2021 • 11 minutes to read • Edit Online

Communication compliance in Microsoft 365 helps minimize communication risks by helping you detect, capture, and act on inappropriate messages in your organization. Pre-defined and custom policies allow you to scan internal and external communications for policy matches so they can be examined by designated reviewers. Reviewers can investigate scanned email, Microsoft Teams, Yammer, or third-party communications in your organization and take appropriate remediation actions to make sure they're compliant with your organization's message standards.

The Contoso Corporation is a fictional organization that needs to quickly configure a policy to monitor for offensive language. They have been using Microsoft 365 primarily for email, Microsoft Teams, and Yammer support for their users but have new requirements to enforce company policy around workplace harassment. Contoso IT administrators and compliance specialists have a basic understanding of the fundamentals of working with Microsoft 365 and are looking for end-to-end guidance for how to quickly get started with communication compliance.

This case study will cover the basics for quickly configuring a communication compliance policy to monitor communications for offensive language. This guidance includes:

- Step 1 - Planning for communication compliance
- Step 2 - Accessing communication compliance in Microsoft 365
- Step 3 - Configuring prerequisites and creating a communication compliance policy
- Step 4 - Investigation and remediation of alerts

Step 1: Planning for communication compliance

Contoso IT administrators and compliance specialists attended online webinars about compliance solutions in Microsoft 365 and decided that communication compliance policies will help them meet the updated corporate policy requirements for reducing workplace harassment. Working together, they've developed a plan to create and enable a communication compliance policy that will monitor for offensive language for chats sent in Microsoft Teams, private messages and community conversations in Yammer, and in email messages sent in Exchange Online. Their plan includes identifying:

- The IT administrators that need access to communication compliance features.
- The compliance specialists that need to create and manage communication policies.
- The compliance specialists and other colleague in other departments (Human Resources, Legal, etc.) that need to investigate and remediate communication compliance alerts.
- The users that will be in-scope for the communication compliance offensive language policy.

Licensing

The first step is to confirm that Contoso's Microsoft 365 licensing includes support for the communication compliance solution. To access and use communication compliance, Contoso IT administrators need to verify that Contoso has one of the following:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on

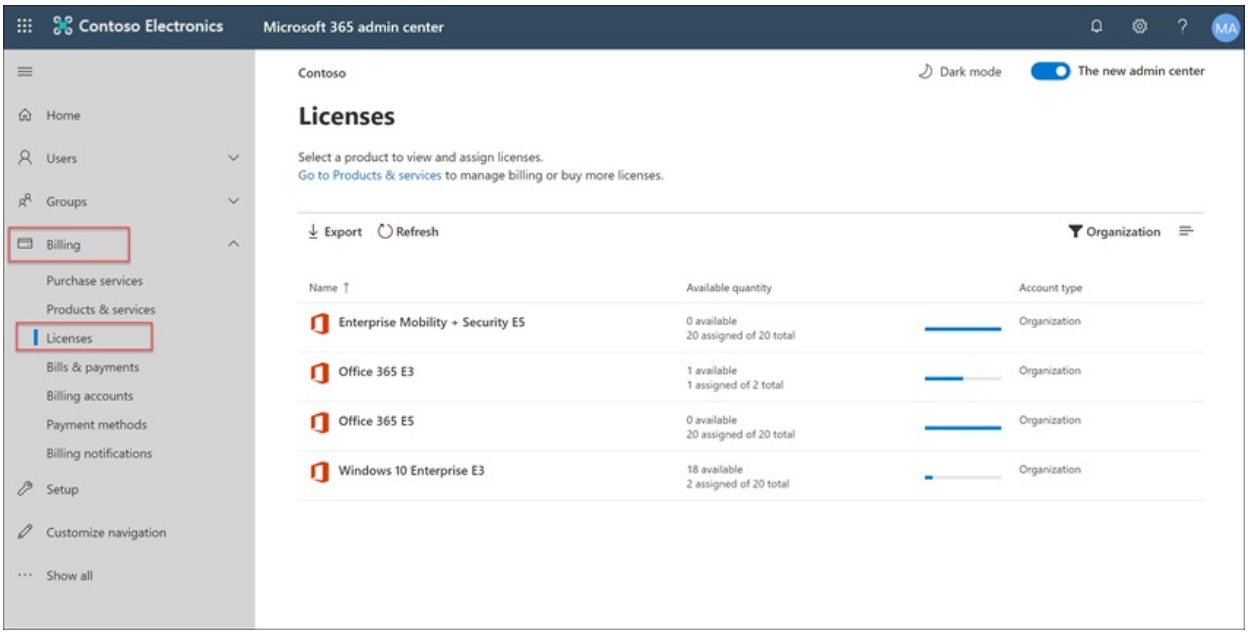
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Microsoft 365 G5 subscription (paid or trial version)
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Compliance add-on
- Microsoft 365 G5 subscription + the Microsoft 365 G5 Insider Risk Management add-on
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 Enterprise E3 subscription + the Office 365 Advanced Compliance add-on (no longer available for new subscriptions, see note)

They must also confirm that users included in communication compliance policies must be assigned one of the licenses above.

> **IMPORTANT**
> Office 365 Advanced Compliance is no longer sold as a standalone subscription. When current subscriptions expire, customers should transition to one of the subscriptions above, which contain the same or additional compliance features.

Contoso IT administrators take the following steps to verify the licensing support for Contoso:

1. IT administrators sign in to the **Microsoft 365 admin center** (https://admin.microsoft.com) and navigate to **Microsoft 365 admin center** > **Billing** > **Licenses**.
2. Here they confirm that they have one of the license options that includes support for communication compliance.



Permissions for communication compliance

There are five role groups used to configure permissions to manage communication compliance features. To make **Communication compliance** available as a menu option in Microsoft 365 compliance center and to continue with these configuration steps, Contoso administrators are assigned the *Communication Compliance Admin* role.

Contoso decides to use the *Communication Compliance* role group assign all the communication compliance administrators, analysts, investigators, and viewers to the group. This makes it easier for Contoso to get started quickly and best fits their compliance management requirements.

ROLE	ROLE PERMISSIONS
Communication Compliance	Use this role group to manage communication compliance for your organization in a single group. By adding all user accounts for designated administrators, analysts, investigators, and viewers, you can configure communication compliance permissions in a single group. This role group contains all the communication compliance permission roles. This configuration is the easiest way to quickly get started with communication compliance and is a good fit for organizations that do not need separate permissions defined for separate groups of users.
Communication Compliance Admin	Use this role group to initially configure communication compliance and later to segregate communication compliance administrators into a defined group. Users assigned to this role group can create, read, update, and delete communication compliance policies, global settings, and role group assignments. Users assigned to this role group cannot view message alerts.
Communication Compliance Analyst	Use this group to assign permissions to users that will act as communication compliance analysts. Users assigned to this role group can view policies where they are assigned as Reviewers, view message metadata (not message content), escalate to additional reviewers, or send notifications to users. Analysts cannot resolve pending alerts.
Communication Compliance Investigator	Use this group to assign permissions to users that will act as communication compliance investigators. Users assigned to this role group can view message metadata and content, escalate to additional reviewers, escalate to an Advanced eDiscovery case, send notifications to users, and resolve the alert.
Communication Compliance Viewer	Use this group to assign permissions to users that will manage communication reports. Users assigned to this role group can access all reporting widgets on the communication compliance home page and can view all communication compliance reports.

1. Contoso IT administrators sign into the **Office 365 Security & Compliance center** permissions page (https://protection.office.com/permissions) using credentials for a global administrator account and select the link to view and manage roles in Microsoft 365.
2. In the **Security & Compliance Center**, they go to **Permissions** and select the link to view and manage roles in Office 365.
3. The administrators select the *Communication Compliance* role group, then select **Edit role group**.
4. The administrators select **Choose members** from the left navigation pane, then select **Edit**.
5. They select **Add** and then select the checkbox for all Contoso users that will manage communication compliance, investigate, and review alerts.
6. The administrators select **Add**, then select **Done**.
7. They select **Save** to add Contoso users to the role group. They select **Close** to complete the steps.

Step 2: Accessing communication compliance in Microsoft 365

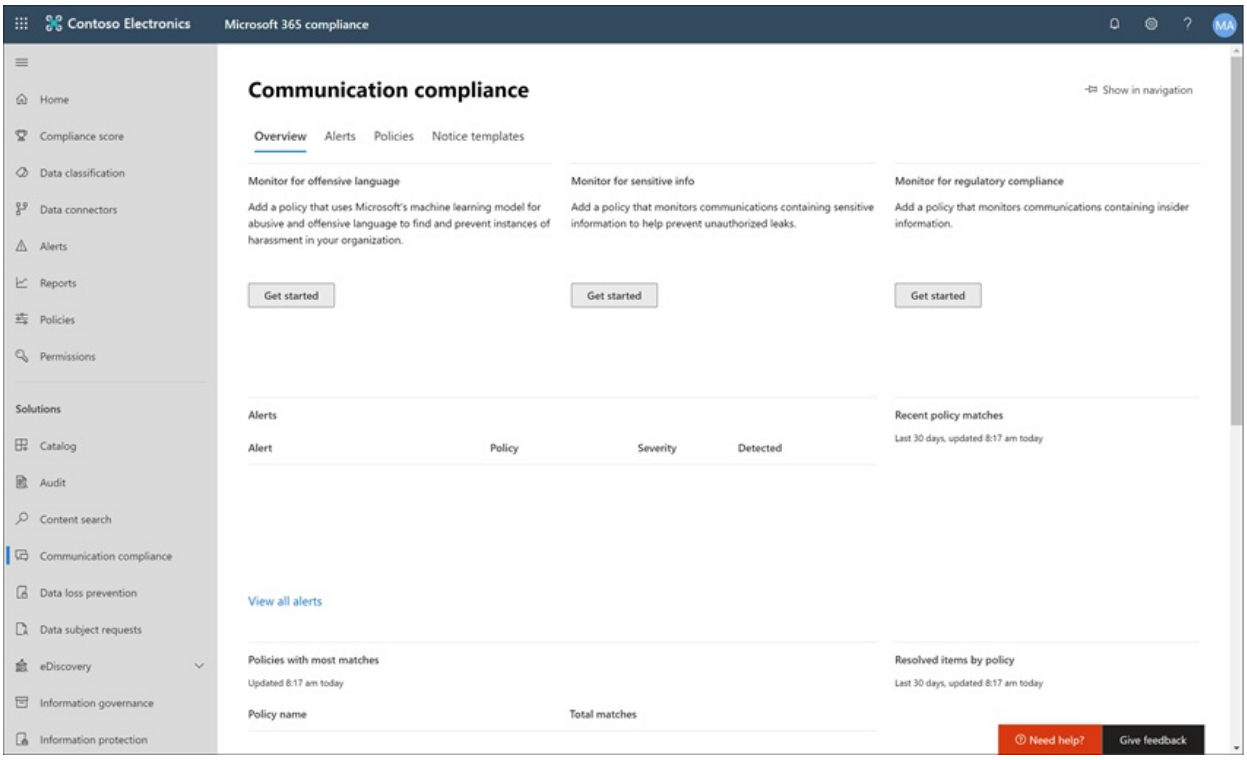
After configuring the permissions for communication compliance, Contoso IT administrators and compliance specialists assigned to the Communication Compliance role group can access the communication compliance

solution in Microsoft 365. Contoso IT administrators and compliance specialists have several ways to access communication compliance and get started creating a new policy:

- Starting directly from the communication compliance solution
- Starting from the Microsoft 365 compliance center
- Starting from the Microsoft 365 solution catalog
- Starting from the Microsoft 365 admin center

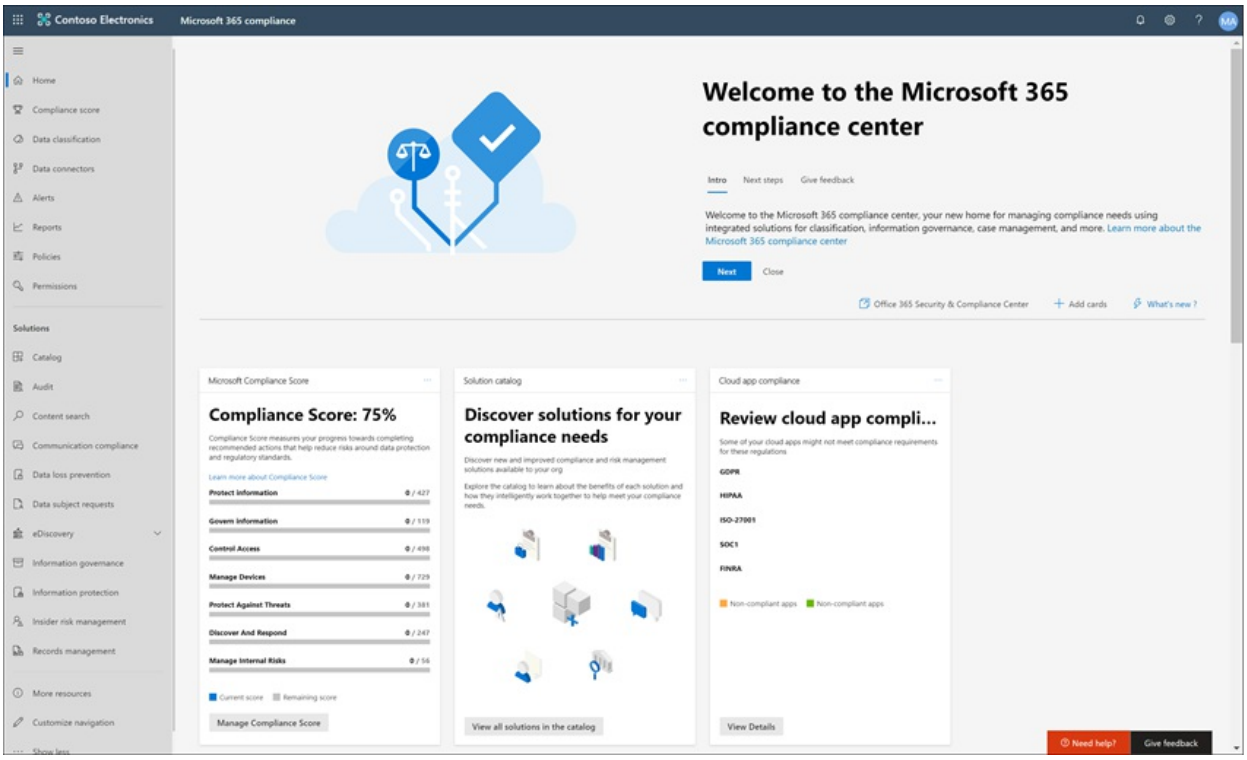
Starting directly from the communication compliance solution

The quickest way to access the solution is to sign in directly to the **Communication compliance** (https://compliance.microsoft.com/supervisoryreview) solution. Using this link, Contoso IT administrators and compliance specialists will be directed to the communication compliance Overview dashboard where you can quickly review the status of alerts and create new policies from the pre-defined templates.



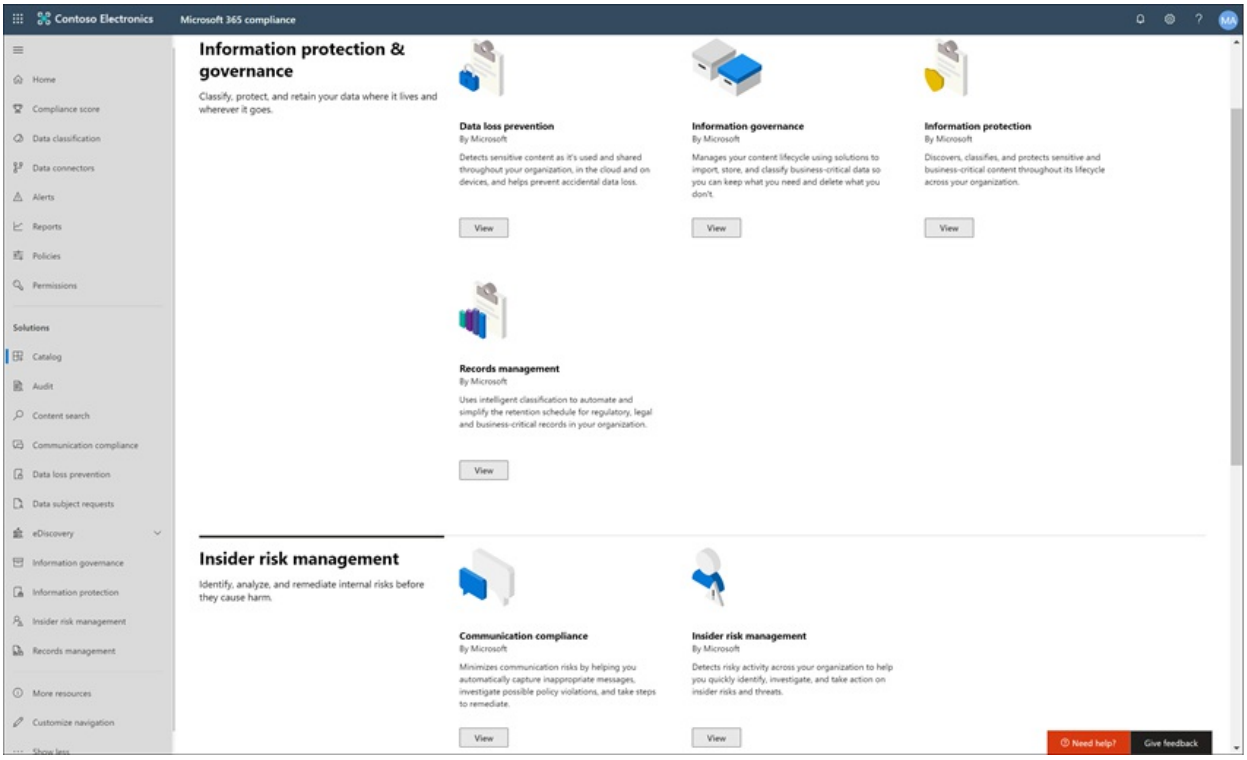
Starting from the Microsoft 365 compliance center

Another easy way for Contoso IT administrators and compliance specialists to access the communication compliance solution is to sign in directly to the **Microsoft 365 compliance center** (https://compliance.microsoft.com). After signing in, users simply need to select the **Show all** control to display all the compliance solutions and then select the **Communication compliance** solution to get started.



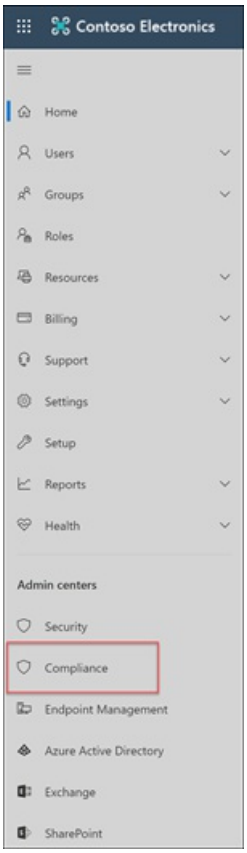
Starting from the Microsoft 365 solution catalog

Contoso IT administrators and compliance specialists could also choose to access the communication compliance solution by selecting the Microsoft 365 solution catalog. By selecting **Catalog** in **Solutions** section of the left navigation while in the **Microsoft 365 compliance center**, they can open the solution catalog listing all Microsoft 365 compliance solutions. Scrolling down to the **Insider risk management** section, Contoso IT administrators can select Communication compliance to get started. Contoso IT administrators also decide to use the Show in navigation control to pin the communication compliance solution to the left-navigation pane for quicker access when they sign in going forward.

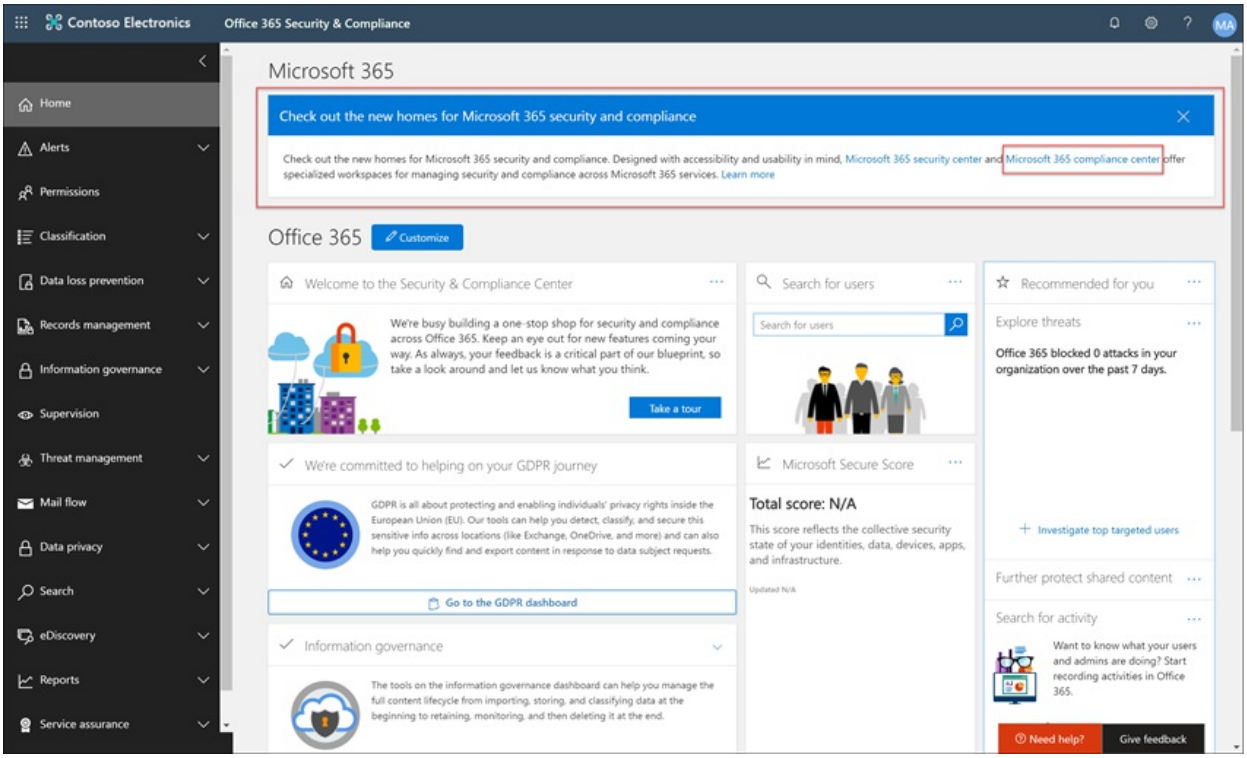


Starting from the Microsoft 365 admin center

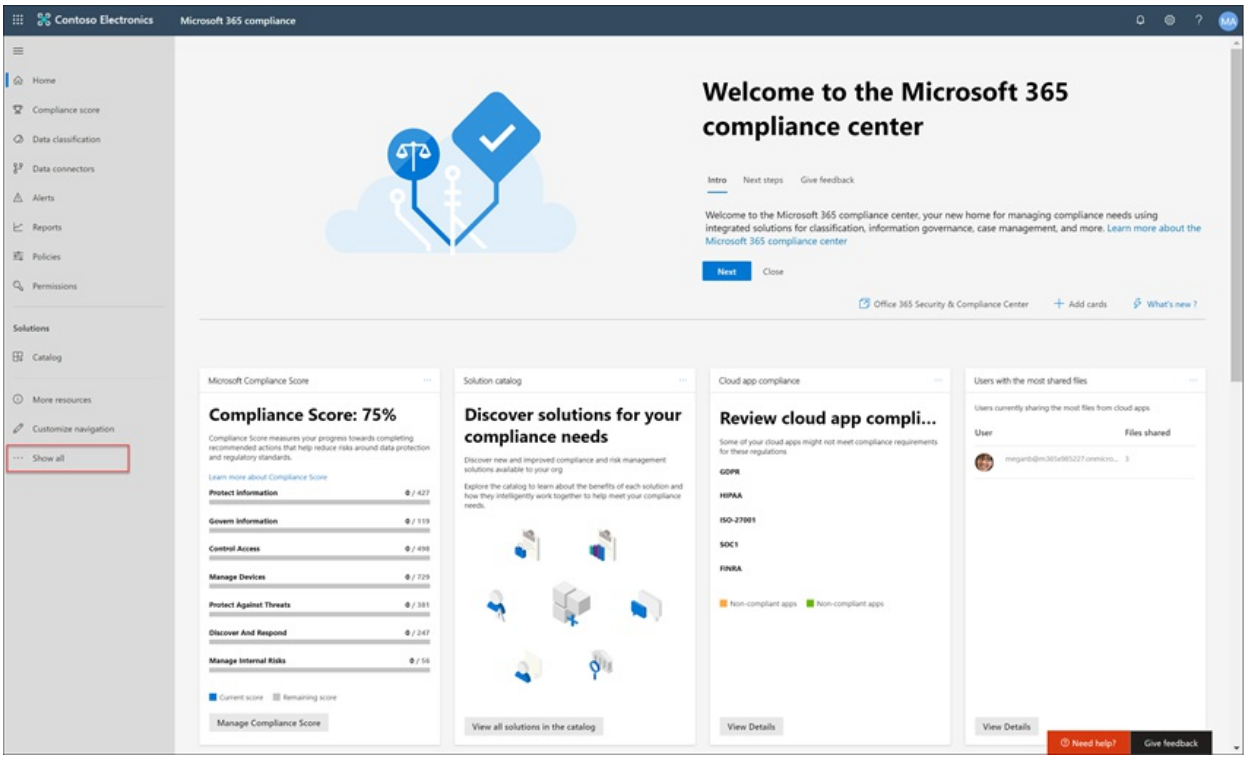
To access communication compliance when starting from the Microsoft 365 admin center, Contoso IT administrators and compliance specialists sign in to the Microsoft 365 admin center (https://admin.microsoft.com) and navigate to **Microsoft 365 admin center** > **Compliance**.



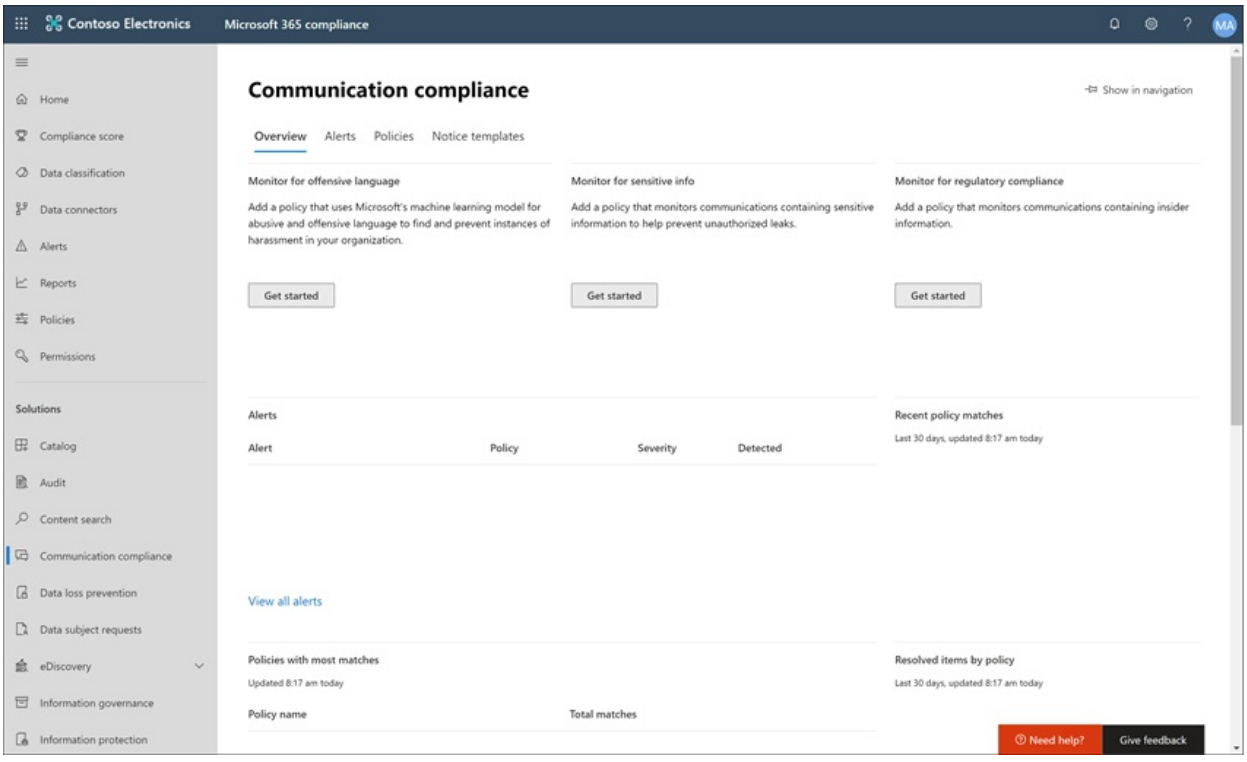
This action opens the **Office 365 Security and Compliance center**, and they must select the link to the **Microsoft 365 compliance center** provided in the banner at the top of the page.



Once in the **Microsoft 365 compliance center**, Contoso IT administrators select **Show all** to display the full list of compliance solutions.



After selecting **Show all**, the Contoso IT administrators can access the communication compliance solution.



Step 3: Configuring prerequisites and creating a communication compliance policy

To get started with a communication compliance policy, there are several prerequisites that Contoso IT administrators need to configure before setting up the new policy to monitor for offensive language. After these prerequisites have been completed, Contoso IT administrators and compliance specialists can configure the new policy and compliance specialists can start investigation and remediating any generated alerts.

Enabling auditing in Microsoft 365

Communication compliance requires audit logs to show alerts and track remediation actions taken by reviewers. The audit logs are a summary of all activities associated with a defined organizational policy or anytime there is

a change to a communication compliance policy.

Contoso IT administrators review and complete the step-by-step instructions to turn on auditing. After they turn on auditing, a message is displayed that says the audit log is being prepared and that they can run a search in a couple of hours after the preparation is complete. The Contoso IT administrators only have to do this action once.

Configuring Yammer tenant for Native Mode

Communication compliance requires that the Yammer tenant for an organization is in Native Mode to monitor for offensive language in private messages and public community conversations.

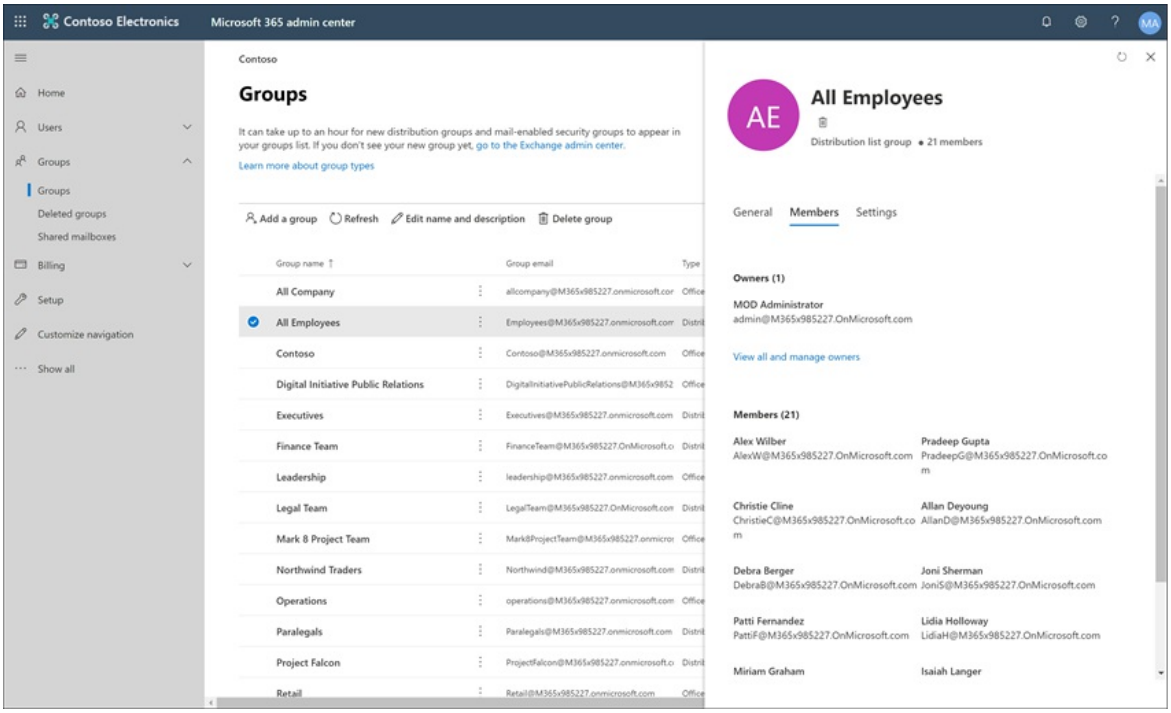
Contoso IT administrators make sure they review the information in the Overview of Yammer Native Mode in Microsoft 365 article and follow the steps for running the migration tool in the Configure your Yammer network for Native Mode for Microsoft 365 article.

Setting up a group for in-scope users

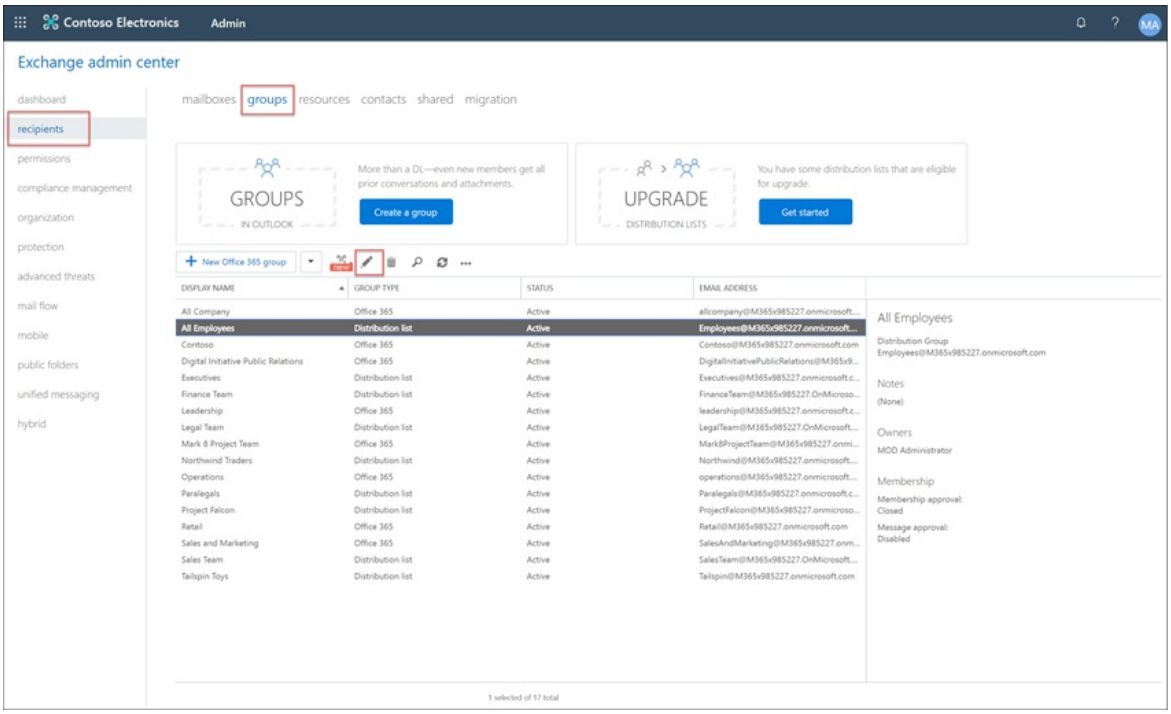
Contoso compliance specialists want to add all users to the communication policy that will monitor for offensive language. They could decide to add each user account to the policy separately, but they've decided it is much easier and saves time to use an **All Users** distribution group for the users for this policy.

They need to create a new group to include all Contoso users, so they take the following steps:

1. Contoso IT administrators IT sign in to the **Microsoft 365 admin center** (https://admin.microsoft.com) and navigate to **Microsoft 365 admin center** > **Groups** > **Groups**.
2. They select **Add a group** and complete the wizard to create a new *Microsoft 365 group* or *Distribution group*.



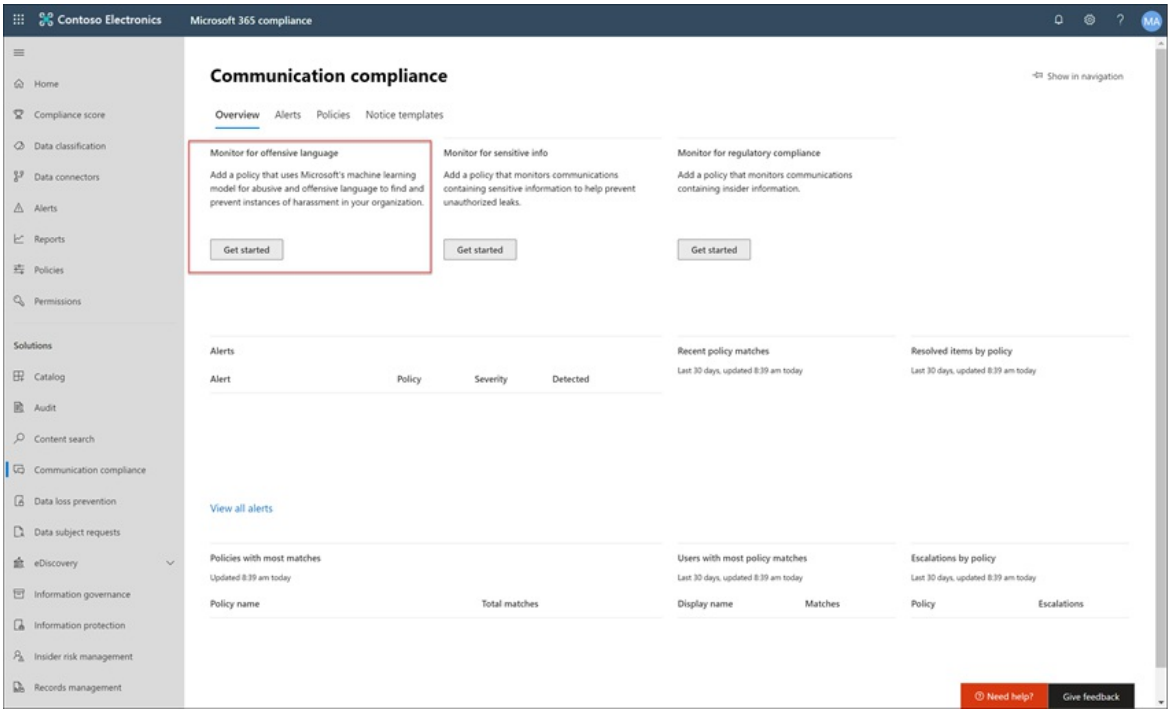
3. After the new group is created, they need to add all Contoso users to the new group. They open the **Exchange admin center** (https://outlook.office365.com/ecp) and navigate to **Exchange admin center** > **recipients** > **groups**. The Contoso IT administrators select the Membership area and the new *All Employees* group they created and select the **Edit** control to add all Contoso users to the new group in the wizard.



Creating the policy to monitor for offensive language

With all the prerequisites completed, the IT administrators and the compliance specialists for Contoso are ready to configure the communication compliance policy to monitor for offensive language. Using the new offensive language policy template, configuring this policy is simple and quick.

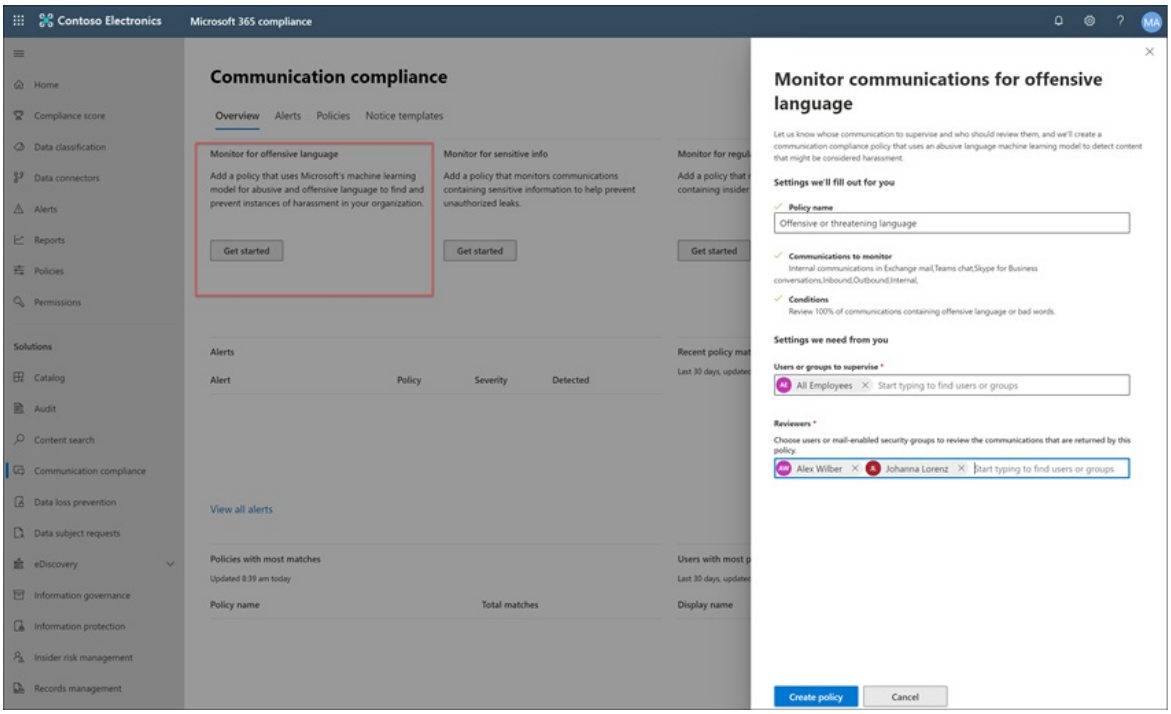
1. The Contoso IT administrators and compliance specialists sign into the **Microsoft 365 compliance center** and select **Communication compliance** from the left navigation pane. This action opens the **Overview** dashboard that has quick links for communication compliance policy templates. They choose the **Monitor for offensive language** template by selecting **Get started** for the template.



2. On the policy template wizard, the Contoso IT administrators and compliance specialists work together to complete the three required fields: **Policy name**, **Users or groups to supervise**, and **Reviewers**.

3. Since the policy wizard has already suggested a name for the policy, the IT administrators and compliance specialists decide to keep the suggested name and focus on the remaining fields. They select the *All users* group for the **Users or groups to supervise** field and select the compliance specialists that should

investigate and remediate policy alerts for the **Reviewers** field. The last step to configure the policy and start gathering alert information is to select **Create policy**.



Step 4: Investigate and remediate alerts

Now that the communication compliance policy to monitor for offensive language is configured, the next step for the Contoso compliance specialists will be to investigate and remediate any alerts generated by the policy. It will take up to 24 hours for the policy to fully process communications in all the communication source channels and for alerts to show up in the **Alert dashboard**.

After alerts are generated, Contoso compliance specialists will follow the workflow instructions to investigate and remediate offensive language issues.

Supervision policies

11/2/2020 • 20 minutes to read • Edit Online

IMPORTANT

Following the release of communication compliance in Microsoft 365 Compliance in February 2020, Supervision in Office 365 is being retired. Supervision policies will no longer be available for creation, and policies will eventually be removed, after an extended period of read only access.

If you use Supervision, be aware that:

- Beginning June 15th, 2020, tenants will not have the ability to create new Supervision policies.
- Beginning August 31st, 2020, existing policies will stop capturing new messages.
- Beginning October 26th, 2020, existing policies will be deleted.

We actively encourage customers who are currently exploring or using Supervision in Office 365 to use the new communication compliance solution to address your communications monitoring or regulatory requirements with a much richer set of intelligent capabilities.

Supervision policies in Microsoft 365 allow you to capture employee communications for examination by designated reviewers. You can define specific policies that capture internal and external email, Microsoft Teams, or 3rd-party communications in your organization. Reviewers can then examine the messages to make sure that they are compliant with your organization's message standards and resolve them with classification type.

These policies can also help you overcome many modern compliance challenges, including:

- Monitoring increasing types of communication channels
- The increasing volume of message data
- Regulatory enforcement & the risk of fines

In some organizations, there may be a separation of duties between IT support and the compliance management group. Microsoft 365 supports the separation between supervision policy feature configuration and the configuration of policies for captured communications. For example, the IT group for an organization may be responsible for setting up role permissions and groups to support supervision policies that are configured and managed by the organization's compliance team.

For a quick overview of Supervision policies, see the Supervision policy video on the Microsoft Mechanics channel.

Transitioning from Supervision

Organizations using supervision policies and planning to transition to communication compliance policies in Microsoft 365 need to understand these important points:

- The supervision solution in Microsoft 365 will be fully replaced by the communication compliance solution in Microsoft 365. For organizations transitioning to communication compliance from supervision policies, we recommend creating new policies in communication compliance that have the same *conditions* as existing supervision policies to enable new investigation and remediation improvements. When transitioning to communication compliance in Microsoft 365, you should plan to export reporting data from supervision if you have internal compliance retention policy requirements.
- In the interim, organizations can use both solutions side by side until fully migrated, but policies used in each solution must have *unique policy names*. Groups and custom keyword dictionaries can be shared between

solutions during the transition period.

- Messages saved in supervision in Microsoft 365 policy matches cannot be moved or shared into communication compliance in Microsoft 365.

For retirement information for supervision in Office 365, see the Microsoft 365 Roadmap for details.

Scenarios for supervision policies

Supervision policies can assist monitoring communications in your organization in several areas:

- **Corporate policies**

  Employees must comply with acceptable use, ethical standards, and other corporate policies in all their business-related communications. Supervision policies can detect policy violations and help you take corrective actions to help mitigate these types of incidents. For example, you could monitor for potential human resources violations such as harassment or the use of inappropriate or offensive language in employee communications.

- **Risk management**

  Organizations are responsible to all communications distributed throughout their infrastructure and corporate network systems. Using supervision policies to help identify and manage potential legal exposure and risk can help minimize risks before they can damage corporate operations. For example, you could monitor your organization for unauthorized communications for confidential projects such as upcoming acquisitions, mergers, earnings disclosures, reorganizations, or leadership team changes.

- **Regulatory compliance**

  Most organizations must comply with some type of regulatory compliance standards as part of their normal operating procedures. These regulations often require organizations to implement some type of supervisory or oversight process for messaging that is appropriate for their industry. The Financial Industry Regulatory Authority (FINRA) Rule 3110 is a good example of a requirement for organizations to have supervisory procedures in place to monitor the activities of its employees and the types of businesses in which it engages. Another example may be a need to monitor broker-dealers in your organization to safeguard against potential money-laundering, insider trading, collusion, or bribery activities. Supervision policies can help your organization meet these requirements by providing a process to both monitor and report on corporate communications.

Components

Supervision policy

You create supervision policies in the Compliance center. These policies define which communications and users are subject to review in your organization, define custom conditions that the communications must meet, and specifies who should perform reviews. Users included in the Supervisory Review role group can set up policies and anyone who has this role assigned can access the Supervision page in the Compliance center.

Supervised users

Before you start using supervision, you must determine who needs their communications reviewed. In the policy, user email addresses identify individuals or groups of people to supervise. Some examples of these groups are Microsoft 365 Groups, Exchange-based distribution lists, and Microsoft Teams channels. You also can exclude specific users or groups from supervision with a supervised group or a list of groups.

IMPORTANT

Users monitored by supervision policies must have a Microsoft 365 E5 Compliance license, an Office 365 Enterprise E3 license with the Advanced Compliance add-on, or be included in an Office 365 Enterprise E5 subscription, or be included in a Microsoft 365 E5 subscription.If you don't have an existing Enterprise E5 plan and want to try supervision, you can sign up for a trial of Office 365 Enterprise E5.

Reviewers

When you create a supervision policy, you must determine who will perform the reviews of the messages of the supervised users. In the policy, user email addresses identify individuals or groups of people to review supervised communications. All reviewers must have mailboxes hosted on Exchange Online.

Groups for supervised users and reviewers

To simplify your setup, create groups for people who need their communications reviewed and groups for people who review those communications. If you're using groups, you might need several. For example, if you want to monitor communications between two distinct groups of people, or if you want to specify a group that isn't supervised.

When you select a Microsoft 365 group for supervised users, the policy monitors the content of the shared mailbox and the Microsoft Teams channels associated with the group. When you select a distribution list, the policy monitors individual user mailboxes.

Supported communication types

With supervision policies, you can choose to monitor messages in one or more of the following communication platforms:

- **Exchange email:** Mailboxes hosted on Exchange Online as part of your Microsoft 365 subscription are all eligible for message supervision. Emails and attachments matching supervision policy conditions are instantly available for monitoring and in supervision reports. Supported attachment types for supervision are the same as the file types supported for Exchange mail flow rule content inspections.
- **Microsoft Teams:** Chat communications and associated attachments in both public and private Microsoft Teams channels and individual chats can be supervised. Teams chats matching supervision policy conditions are processed once every 24 hours and then are available for monitoring and in supervision reports. Use the following group management configurations to supervise individual user chats and channel communications in Teams:
  - **For Teams chat supervision:** Assign individual users or assign a distribution group to the supervision policy. This configuration is for 1-to-1 or 1-to-many user/chat relationships.
  - **For Teams Channel communications:** Assign every Microsoft Team channel or Microsoft 365 group you want to monitor that contains a specific user to the supervision policy. If you add the same user to other Microsoft Teams channels or Microsoft 365 groups, be sure to add these new channels and groups to the supervision policy.
- **Skype for Business Online:** Chat communications and associated attachments in Skype for Business Online can be supervised. Skype for Business Online chats matching supervision policy conditions are processed once every 24 hours and then are available for monitoring and in supervision reports. Supervised chat conversations are sourced from previous conversations saved in Skype for Business Online. Use the following group management configuration to supervise user chat communications in Skype for Business Online:
  - **For Skype for Business Online chat supervision:** Assign individual users or assign a distribution group to the supervision policy. This configuration is for 1-to-1 or 1-to-many user/chat relationships.
- **Third-party sources:** You can supervise communications from third-party sources (like from Facebook or DropBox) for data imported into mailboxes in your organization. Learn how to import 3rd-party data.

Communications captured across these platforms are retained for seven years for each policy by default, even if users leave your organization and their mailbox is deleted.

Policy settings

Direction

By default, the **Direction is** condition is displayed and can't be removed. Communication direction settings in a policy are chosen individually or together:

- **Inbound**: You can choose **Inbound** to review communications sent **to** the people you chose to supervise **from** people not included in the policy.
- **Outbound**: You can choose **Outbound** if you want to review communications sent **from** the people you chose to supervise **to** people not included in the policy.
- **Internal**: You can choose **Internal** to review communications sent **between** the people you identified in the policy.

Sensitive information types

You have the option of including sensitive information types as part of your supervision policy. Sensitive information types are either pre-defined or custom data types that can help identify and protect credit card numbers, bank account numbers, passport numbers, and more. As a part of data loss prevention (DLP), the sensitive information configuration can use patterns, character proximity, confidence levels, and even custom data types to help identify and flag content that may be sensitive. The default sensitive information types are:

- Financial
- Medical and health
- Privacy
- Custom information type

To learn more about sensitive information details and the patterns included in the default types, see Sensitive information type entity definitions.

Custom keyword dictionaries

Configure custom keyword dictionaries (or lexicons) to provide simple management of keywords specific to your organization or industry. Keyword dictionaries support up to 100KB of terms (post compression) in the dictionary and support any language. The tenant limit is also 100KB after compression. If needed, you can apply multiple custom keyword dictionaries to a single policy or have a single keyword dictionary per policy. These dictionaries are assigned in a supervision policy and can be sourced from a file (such as a .csv or .txt list), or from a list you can import in the Compliance center.

Offensive language

Monitor sent or received email messages in your organization for offensive language. The model uses a combination of machine learning, artificial intelligence, and keywords to identify language in email messages likely to violate anti-harassment and bullying policies. The offensive language model currently supports English keywords and monitors the body of email messages.

> **NOTE**
>
> Create a data loss prevention policy with a custom keyword dictionary of blocked terms if you need to:
>
> - monitor Microsoft Teams communications in your organization for offensive language
> - prevent or block offensive language in communications in your organization

The model does not provide an exhaustive list of offensive language. Further, language and cultural standards continually change, and in light of these realities, Microsoft reserves the right to update the model in its discretion. While the model may assist your organization in monitoring offensive language, the model is not intended to provide your organization's sole means of monitoring or addressing such language. Your

organization, not Microsoft, remains responsible for all decisions related to monitoring and blocking offensive language.

The offensive language model monitors email for sentiment associated with the following types of language:

TYPE	DESCRIPTION
Profanities	Expressions that embarrass most people.
Slurs	Expressions that express prejudice against particular groups (for example, race, ethnicity, sexual orientation, disability).
Taunts	Expressions that taunt, condemn, ridicule, or could potentially cause anger or violence.
Disguised expressions	Expressions for which the meaning or pronunciation is the same as another more offensive term.

Conditional settings

The conditions you choose for the policy apply to communications from both email and 3rd-party sources in your organization (like from Facebook or DropBox).

The following table explains more about each condition.

CONDITION	HOW TO USE THIS CONDITION
Message is received from any of these domains **Message is not received from any of these domains**	Apply the policy to include or exclude specific domains or email addresses in received messages. Enter each domain or email address and separate multiple domains or email addresses with a comma. Each domain or email address entered is applied separately, only one domain or email address must apply for the policy to apply to the message. If you want to monitor all email from a specific domain but want to exclude messages that do not need review (newsletters, announcements, etc.), you must configure the condition a **Message is not received from any of these domains** condition that excludes the email address (example "newsletter@contoso.com").
Message is sent to any of these domains **Message is not sent to any of these domains**	Apply the policy to include or exclude specific domains or email addresses in sent messages. Enter each domain or email address and separate multiple domains or email addresses with a comma. Each domain or email address is applied separately, only one domain or email address must apply for the policy to apply to the message. If you want to monitor all email sent to a specific domain but want to exclude sent messages that do not need review, you must configure two conditions: - A **Message is sent to any of these domains** condition that defines the domain ("contoso.com"), AND - A **Message is not sent to any of these domains** condition that excludes the email address ("subscriptions@contoso.com").

CONDITION	HOW TO USE THIS CONDITION
Message is classified with any of these labels **Message is not classified with any of these labels**	To apply the policy when certain retention labels are included or excluded in a message. Retention labels must be configured separately and configured labels are chosen as part of this condition. Each label you choose is applied separately (only one of these labels must apply for the policy to apply to the message). For more information about retention labels, see Learn about retention policies and retention labels.
Message contains any of these words **Message contains none of these words**	To apply the policy when certain words or phrases are included or excluded in a message, enter each word or phrase and separate with a comma. Each word you enter is applied separately (only one word must apply for the policy to apply to the message). For more information about entering words or phrases, see the next section Matching words and phrases to emails or attachments.
Attachment contains any of these words **Attachment contains none of these words**	To apply the policy when certain words or phrases are included or excluded in a message attachment (such as a Word document), enter each word or phrase and separate with a comma. Each word you enter is applied separately (only one word must apply for the policy to apply to the attachment). For more information about entering words or phrases, see the next section Matching words and phrases to emails or attachments.
Attachment is any of these file types **Attachment is none of these file types**	To supervise communications that include or exclude specific types of attachments, enter the file extensions (such as .exe or .pdf). If you want to include or exclude multiple file extensions, enter these on separate lines. Only one attachment extension must match for the policy to apply.
Message size is larger than **Message size is not larger than**	To review messages based on a certain size, use these conditions to specify the maximum or minimum size a message can be before it is subject to review. For example, if you specify **Message size is larger than** > **1.0 MB**, all messages that are 1.01 MB and larger are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.
Attachment is larger than **Attachment is not larger than**	To review messages based on the size of their attachments, specify the maximum or minimum size an attachment can be before the message and its attachments are subject to review. For example, if you specify **Attachment is larger than** > **2.0 MB**, all messages with attachments 2.01 MB and over are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.

Matching words and phrases to emails or attachments

Each word you enter and separate with a comma is applied separately (only one word must apply for the policy condition to apply to the email or attachment). For example, let's use the condition, **Message contains any of these words**, with the keywords "banker" and "insider trading" separated by a comma (banker, insider trading). The policy applies to any messages that includes the word "banker" or the phrase "insider trading". Only one of these words or phrases must occur for this policy condition to apply. Words in the message or attachment must exactly match what you enter.

To scan both email messages and attachments for the same keywords, create a data loss prevention policy with a custom keyword dictionary for the terms you wish to monitor. This policy configuration identifies defined

keywords that appear in either the email message **OR** in the email attachment. Using the standard conditional policy settings (*Message contains any of these words* and *Attachment contains any of these words*) to identify terms in messages and in attachments requires the terms are present in **BOTH** the message and the attachment.

Enter multiple conditions

If you enter multiple conditions, Microsoft 365 uses all the conditions together to determine when to apply the policy to communication items. When you set up multiple conditions, all conditions must be met for the policy to apply, unless you enter an exception. For example, you need a policy that applies if a message contains the word "trade", and is larger than 2 MB. However, if the message also contains the words "Approved by Contoso financial", the policy should not apply. Thus, in this case, the three conditions would be as follows:

- **Message contains any of these words**, with the keyword "trade"
- **Message size is larger than**, with the value 2 MB
- **Message contains none of these words**, with the keywords "Approved by Contoso financial team"

Review percentage

If you want to reduce the amount of content to review, you can specify a percentage of all the communications governed by a supervision policy. A real-time, random sample of content is selected from the total percentage of content that matches chosen policy conditions. If you want reviewers to review all items, you can enter **100%** in a supervision policy.

Monitor & manage

It is easy to monitor the results of your supervision policies and apply a resolution tag. You can quickly see:

- The status of reviewed items
- Users and groups under supervision
- Users and groups designated as reviewers

Supervision policy dashboard

Use the supervision policy dashboard to manage supervision policy results and to resolve outstanding items. This dashboard allows reviewers to view items that need to be reviewed, act on an item, and review the results of previously reviewed and resolved items for each supervision policy. You can access the supervision policy dashboard in the Compliance center at **Supervision** > *Your Custom Policy* > **Open**.

Dashboard Home

The dashboard **Home** page has several sections to help you quickly act on your supervision policies. Here you can:

- Quickly review the pending and resolved highlights for the week
- See a list of the supervised users and supervised groups for the selected policy
- See a list of the reviewers and review teams for the selected policy
- See which communication platforms have content under supervision for the policy

Review tab

The **Review** tab is where reviewers classify and resolve items identified by the selected policy. Here you can:

- Filter by pending, compliant, non-compliant, and questionable items.
- Tag a single item as compliant, non-compliant, or questionable. You can also record a comment with the item to help clarify the tagging action taken.
- Bulk tag multiple items as compliant, non-compliant, or questionable. You can also record a comment with multiple items to help clarify the tagging action taken.
- View the history of the tagging for a single item. Includes who resolved the item, the date and time of the action, the resolution tag, and any included comments.

- Reclassify previously reviewed items as compliant, non-compliant, or questionable. You can also record a comment with single or multiple items to help clarify the reclassification action taken.

Resolved Items tab

The **Resolved Items** tab is where reviewers can view all previously resolved items for the selected policy. Here you can:

- Quickly view and sort the subject, sender, and date of resolved items
- View the classification and comment history of any selected item

Reports

Use the supervision reports to see the review activity at the policy and reviewer level. For each policy, you can also view live statistics on the current state of review activity. You can use the supervision reports to:

- Verify that your policies are working as you intended.
- Find out how many communications need review.
- Find out how many communications aren't compliant and which ones are passing review. This information can help you decide whether to fine-tune your policies or change the number of reviewers.

View the Supervision report

1. Sign into the Compliance center with credentials for an admin account with permissions to view supervision reports.
2. Go to either **Reports** > **Dashboard** or **Supervision** to view the supervision reporting widget for a summary of current supervision policy activity.
3. Select the **Supervision** widget to open the detailed report page.

> **NOTE**
> If you aren't able to access the **Reports** page, check that you're a member of the Supervisory Review role group, as described in Make supervision available in your organization. Inclusion in this role group lets you create and manage supervision polices and run the report.

How to use the report

This report lists each policy and the number of communications at each stage in the review process. Use the report to:

- View data for all or specific policies.
- View data grouped by tag type, reviewer, or message type.
- Export data to a CSV file based on activity date, policy, and by reviewer activity.
- Filter data based on activity date, tag type, reviewer, and message type.

Here's a breakdown of the values displayed the **Tag type** column.

TAG TYPE	WHAT IT MEANS
Not Reviewed	The number of emails not reviewed yet. These emails are awaiting review in the Microsoft 365 supervision dashboard.
Compliant	The number of emails reviewed and marked as compliant. These messages still need resolution.

TAG TYPE	WHAT IT MEANS
Questionable	The number of emails reviewed and marked questionable. Serves as a flag for other reviewers to help check whether an email needs investigation for compliance. These messages still need resolution.
Non-Compliant (Active)	The number of non-compliant emails that reviewers are currently investigating.
Non-Compliant (Resolved)	The number of non-compliant emails that reviewers investigated and resolved.
Hit Policy	The total number (daily) of messages from Exchange, Teams, and third-party data sources that matched one or more conditions defined in a supervision policy
In Purview	The total number (daily) of messages from Exchange, Teams, and third-party data sources scanned by a supervision policy
Resolved	The total number of messages from Exchange, Teams, and third-party data sources classified as **Resolved**

> **NOTE**
>
> Supervision policies must be provisioned before they appear in reports. If policies are deleted, historical data is still shown. However, they're indicated as a "Non-existent policy" and the **Export** function isn't available.

Audit

In some instances, you must provide information to regulatory or compliance auditors to prove supervision of employee activities and communications. This information may be a summary of all supervisory activities associated with a defined policy or anytime a supervision policy changes. Supervision policies have built-in audit trails for complete readiness for internal or external audits. Detailed audit histories of every action monitored by your supervision policies provide proof of supervisory procedures.

View audit activities in the unified audit log or with the Search-UnifiedAuditLog PowerShell cmdlet.

For example, the following example returns the activities for the all the supervisory review activities (policies and rules) and lists detailed information for each:

```
Search-UnifiedAuditLog -StartDate 3/1/2019 -EndDate ([System.DateTime]::Now) -RecordType DataGovernance -
ResultSize 5000 | Where-Object {$_.Operations -like "*SupervisoryReview*"}  | fl
CreationDate,Operations,UserIds,AuditData
```

This example returns the update activities for your communication compliance policies:

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -Operations
SupervisionPolicyCreated,SupervisionPolicyUpdated,SupervisionPolicyDeletedAuditData
```

In addition to information provided in the supervision reports and logs, you can also use the Get-SupervisoryReviewActivity PowerShell cmdlet to return a complete detailed listing of all supervision policy activities.

Ready to get started?

To configure supervision policies for your organization, see Configure supervision policies.

Configure supervision policies in Office 365

11/2/2020 • 8 minutes to read • Edit Online

IMPORTANT

Following the release of communication compliance in Microsoft 365 Compliance in February 2020, Supervision in Office 365 is being retired. Supervision policies will no longer be available for creation, and policies will eventually be removed, after an extended period of read only access.

If you use Supervision, be aware that:

- Beginning June 15th, 2020, tenants will not have the ability to create new Supervision policies.
- Beginning August 31st, 2020, existing policies will stop capturing new messages.
- Beginning October 26th, 2020, existing policies will be deleted.

We actively encourage customers who are currently exploring or using Supervision in Office 365 to use the new communication compliance solution to address your communications monitoring or regulatory requirements with a much richer set of intelligent capabilities.

Use supervision policies to capture employee communications for examination by internal or external reviewers. For more information about how supervision policies can help you monitor communications in your organization, see Supervision policies in Office 365.

NOTE

Users monitored by supervision policies must have a Microsoft 365 E5 Compliance license, an Office 365 Enterprise E3 license with the Advanced Compliance add-on, or be included in an Office 365 Enterprise E5 subscription, or be included in a Microsoft 365 E5 subscription. If you don't have an existing Enterprise E5 plan and want to try supervision, you can sign up for a trial of Office 365 Enterprise E5.

Follow these steps to set up and use supervision in your organization:

- **Step 1 (optional)**: Set up groups for supervision

  Before you start using supervision policies, determine who needs communications reviewed and who performs reviews. If you want to get started with just a few users to see how supervision works, you can skip setting up groups for now.

- **Step 2 (required)**: Make supervision available in your organization

  Add yourself to the Supervisory Review role group so you can set up policies. Anyone who has this role assigned can access the **Supervision** page in the Security & Compliance Center. If reviewable email is hosted on Exchange Online, each reviewer must have remote PowerShell access to Exchange Online.

- **Step 3 (optional)**: Create custom sensitive information types and custom keyword dictionaries

  If you need a custom sensitive info type or a custom keyword dictionary for your supervision policy, you need to create it before starting the supervision wizard.

- **Step 4 (required)**: Set up a supervision policy

  You create supervision policies in the Security & Compliance Center. These policies define which communications are subject to review in your organization and specifies who performs reviews.

Communications include email and Microsoft Teams communications, and 3rd-party platform communications (such as Facebook, Twitter, etc.). Supervision policies created in organizations are not supported in communication supervision in Microsoft 365 subscriptions.

- **Step 5 (optional)**: Test your communication supervision policy

  Test your supervision policy to make sure it functions as desired. It is important to ensure that your compliance strategy is meeting your standards.

Step 1: Set up groups for supervision (optional)

When you create a supervision policy, you define who has their communications scanned and who performs reviews. In the policy, you'll use email addresses to identify individuals or groups of people. To simplify your setup, you can create groups for people who have their communication scanned and groups for people who review those communications. If you're using groups, you may need several. For example, you want to monitor communications between two distinct groups of people or if you want to specify a group that isn't going to be supervised.

Use the following chart to help you configure groups in your organization for communication supervision policies:

POLICY MEMBER	SUPPORTED GROUPS	UNSUPPORTED GROUPS
Supervised users Non-supervised users	Distribution groups Microsoft 365 groups	Dynamic distribution groups
Reviewers	Mail-enabled security groups	Distribution groups Dynamic distribution groups

When you select a Microsoft 365 group for supervised users, the policy monitors the content of the shared mailbox and the Microsoft Teams channels associated with the group. When you select a distribution list, the policy monitors individual user mailboxes.

To manage supervised users in large enterprise organizations, you may need to monitor all users across large groups. You can use PowerShell to configure a distribution group for a global supervision policy for the assigned group. This enables you to monitor thousands of users with a single policy and keep the supervision policy updated as new employees join your organization.

1. Create a dedicated distribution group for your global supervision policy with the following properties: Make sure that this distribution group isn't used for other purposes or other Office 365 services.

   - **MemberDepartRestriction = Closed**. Ensures that users cannot remove themselves from the distribution group.
   - **MemberJoinRestriction = Closed**. Ensures that users cannot add themselves to the distribution group.
   - **ModerationEnabled = True**. Ensures that all messages sent to this group are subject to approval and that the group is not being used to communicate outside of the supervision policy configuration.

   ```
   New-DistributionGroup -Name <your group name> -Alias <your group alias> -MemberDepartRestriction
   'Closed' -MemberJoinRestriction 'Closed' -ModerationEnabled $true
   ```

2. Select an unused Exchange custom attribute to track users added to the supervision policy in your organization.

3. Run the following PowerShell script on a recurring schedule to add users to the supervision policy:

```
$Mbx = (Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited -Filter {CustomAttribute9
-eq $Null})
$i = 0
ForEach ($M in $Mbx)
{
  Write-Host "Adding" $M.DisplayName
  Add-DistributionGroupMember -Identity <your group name> -Member $M.DistinguishedName -ErrorAction
SilentlyContinue
  Set-Mailbox -Identity $M.Alias -<your custom attribute name> SRAdded
  $i++
}
Write-Host $i "Mailboxes added to supervisory review distribution group."
```

For more information about setting up groups, see:

- Create and manage distribution groups
- Manage mail-enabled security groups
- Overview of Microsoft 365 Groups

Step 2: Make supervision available in your organization (required)

To make **Supervision** available as a menu option in Security & Compliance Center, you must be assigned the Supervisory Review Administrator role.

To do this, you can either add yourself as a member of the Supervisory Review role group, or you can create a role group.

Add members to the Supervisory Review role group

1. Sign into https://protection.office.com using credentials for an admin account in your organization.
2. In the Security & Compliance Center, go to **Permissions**.
3. Select the **Supervisory Review** role group and then click the Edit icon.
4. In the **Members** section, add the people who you want to manage communication supervision for your organization.

Create a new role group

1. Sign into https://protection.office.com/permissions using credentials for an admin account in your organization.
2. In the Security & Compliance Center, go to **Permissions** and then click Add (+).
3. In the **Roles** section, click Add (+) and scroll down to **Supervisory Review Administrator**. Add this role to the role group.
4. In the **Members** section, add the people who you want to manage communication supervision for your organization.

For more information about role groups and permissions, see Permissions in the Compliance Center.

Enable remote PowerShell access for reviewers (if email is hosted on Exchange Online)

1. Follow the guidance in Enable or disable access to Exchange Online PowerShell.

Step 3: Create custom sensitive information types and custom keyword dictionaries (optional)

In order to pick from existing custom sensitive information types or custom keyword dictionaries in the

supervision policy wizard, you first need to create these items if needed.

Create custom keyword dictionary/lexicon (optional)

Use a text editor (like Notepad), to create a file that includes the keyword terms you'd like to monitor in a supervision policy. Make sure that each term is on a separate line and save the file in the **Unicode/UTF-16 (Little Endian)** format.

Create custom sensitive information types

1. Create a new sensitive information type and add your custom dictionary in the Security & Compliance Center. Navigate to **Classifications** > **Sensitive info types** and follow the steps in the **New sensitive info type wizard**. Here you will:

   - Define a name and description for the sensitive info type
   - Define the proximity, confidence level, and primary pattern elements
   - Import your custom dictionary as a requirement for the matching element
   - Review your selections and create the sensitive info type

   For more detailed information, see Create a custom sensitive information type and Create a keyword dictionary

   After the custom dictionary/lexicon is created, you can view the configured keywords with the Get-DlpKeywordDictionary cmdlet or add and remove terms using the Set-DlpKeywordDictionary cmdlet.

Step 4: Set up a supervision policy (required)

1. Sign into https://protection.office.com using credentials for an admin account in your organization.
2. In the Security & Compliance Center, select **Supervision**.
3. Select **Create** and follow the wizard to set up the policy configuration. Using the wizard, you will:

   - Give the policy a name and description.
   - Choose the users or groups to supervise, including choosing users or groups you'd like to exclude.
   - Define the supervision policy conditions. You can choose from message address, keyword, file types, and size match conditions.
   - Choose if you'd like to include sensitive information types. This is where you can select default and custom sensitive info types.
   - Choose if you'd like to enable the offensive language model. This detects inappropriate language sent or received in the body of email messages.
   - Define the percentage of communications to review.
   - Choose the reviewers for the policy. Reviewers can be individual users or mail-enabled security groups. All reviewers must have mailboxes hosted on Exchange Online.
   - Review your policy selections and create the policy.

Step 5: Test your supervision policy (optional)

After you create a communication supervision policy, it's a good idea to test to make sure that the conditions you defined are being properly enforced by the policy. You may also want to test your data loss prevention (DLP) policies if your supervision policies include sensitive information types. Follow these steps to test your supervision policy:

1. Open an email client or Microsoft Teams logged in as a supervised user defined in the policy you want to test.
2. Send an email or Microsoft Teams chat that meets the criteria you've defined in the supervision policy. This can be a keyword, attachment size, domain, etc. Make sure that you determine if your configured

conditional settings in the policy are too restrictive or too lenient.

> **NOTE**
>
> Emails subject to defined policies are processed in near real-time and can be tested immediately after the policy is configured. Chats in Microsoft Teams can take up to 24 hours to fully process in a policy.

3. Log into Microsoft 365 as a reviewer designated in the communication supervision policy. Navigate to **Supervision** > *Your Custom Policy* > **Open** to view the report for the policy.

Insider risk management in Microsoft 365

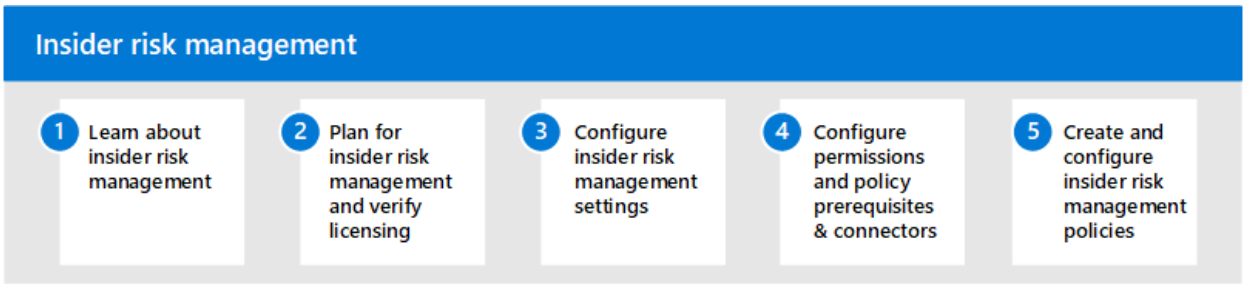
2/18/2021 • 2 minutes to read • Edit Online

Increasingly, employees have more access to create, manage, and share data across a broad spectrum of platforms and services. In most cases, organizations have limited resources and tools to identify and mitigate organization-wide risks while also meeting compliance requirements and employee privacy standards. These risks may include data theft by departing employees and data leaks of information outside your organization by accidental oversharing or malicious intent.

Insider risk management in Microsoft 365 uses the full breadth of service and 3rd-party indicators to help you quickly identify, triage, and act on risky user activity. By using logs from Microsoft 365 and Microsoft Graph, insider risk management allows you to define specific policies to identify risk indicators and to take action to mitigate these risks.

Configure insider risk management for Microsoft 365

Use the following steps to configure insider risk management for your organization:



1. Learn about insider risk management in Microsoft 365
2. Plan for insider risk management and verify licensing
3. Configure insider risk management settings
4. Configure permissions and policy prerequisites & connectors
5. Create and configure insider risk management policies

More information about insider risk management

- Manage insider risk policies
- Investigate insider risk alerts
- Act on insider risk cases

Learn about insider risk management in Microsoft 365

2/18/2021 • 10 minutes to read • Edit Online

Insider risk management is a compliance solution in Microsoft 365 that helps minimize internal risks by enabling you to detect, investigate, and act on malicious and inadvertent activities in your organization. Insider risk policies allow you to define the types of risks to identify and detect in your organization, including acting on cases and escalating cases to Microsoft Advanced eDiscovery if needed. Risk analysts in your organization can quickly take appropriate actions to make sure users are compliant with your organization's compliance standards.

Watch the video below to learn how insider risk management can help your organization prevent, detect, and contain risks while prioritizing your organization values, culture, and user experience:

Modern risk pain points

Managing and minimizing risk in your organization starts with understanding the types of risks found in the modern workplace. Some risks are driven by external events and factors that are outside of direct control. Other risks are driven by internal events and user activities that can be minimized and avoided. Some examples are risks from illegal, inappropriate, unauthorized, or unethical behavior and actions by users in your organization. These behaviors include a broad range of internal risks from users:

- Leaks of sensitive data and data spillage
- Confidentiality violations
- Intellectual property (IP) theft
- Fraud
- Insider trading
- Regulatory compliance violations

Users in the modern workplace have access to create, manage, and share data across a broad spectrum of platforms and services. In most cases, organizations have limited resources and tools to identify and mitigate organization-wide risks while also meeting user privacy standards.

Insider risk management uses the full breadth of service and 3rd-party indicators to help you quickly identify, triage, and act on risk activity. By using logs from Microsoft 365 and Microsoft Graph, insider risk management allows you to define specific policies to identify risk indicators. These policies allow you to identify risky activities and to act to mitigate these risks.

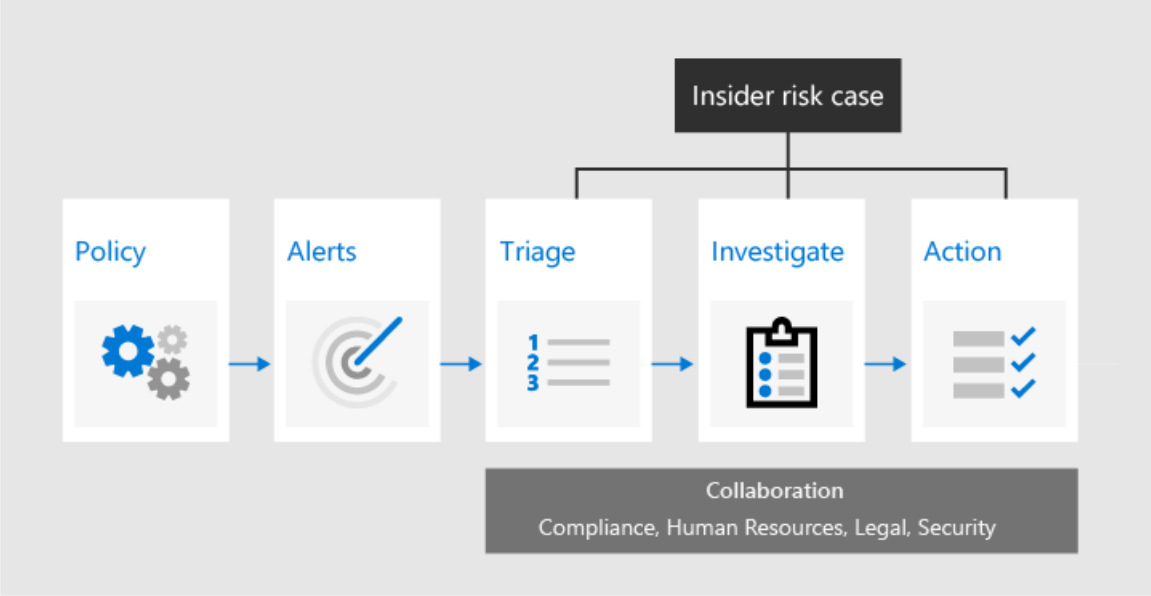
Insider risk management is centered around the following principles:

- **Transparency**: Balance user privacy versus organization risk with privacy-by-design architecture.
- **Configurable**: Configurable policies based on industry, geographical, and business groups.
- **Integrated**: Integrated workflow across Microsoft 365 compliance solutions.
- **Actionable**: Provides insights to enable user notifications, data investigations, and user investigations.

Workflow

The insider risk management workflow helps you identify, investigate, and take action to address internal risks in your organization. With focused policy templates, comprehensive activity signaling across the Microsoft 365 service, and alert and case management tools, you can use actionable insights to quickly identify and act on risky behavior.

Identifying and resolving internal risk activities and compliance issues with insider risk management in Microsoft 365 uses the following workflow:

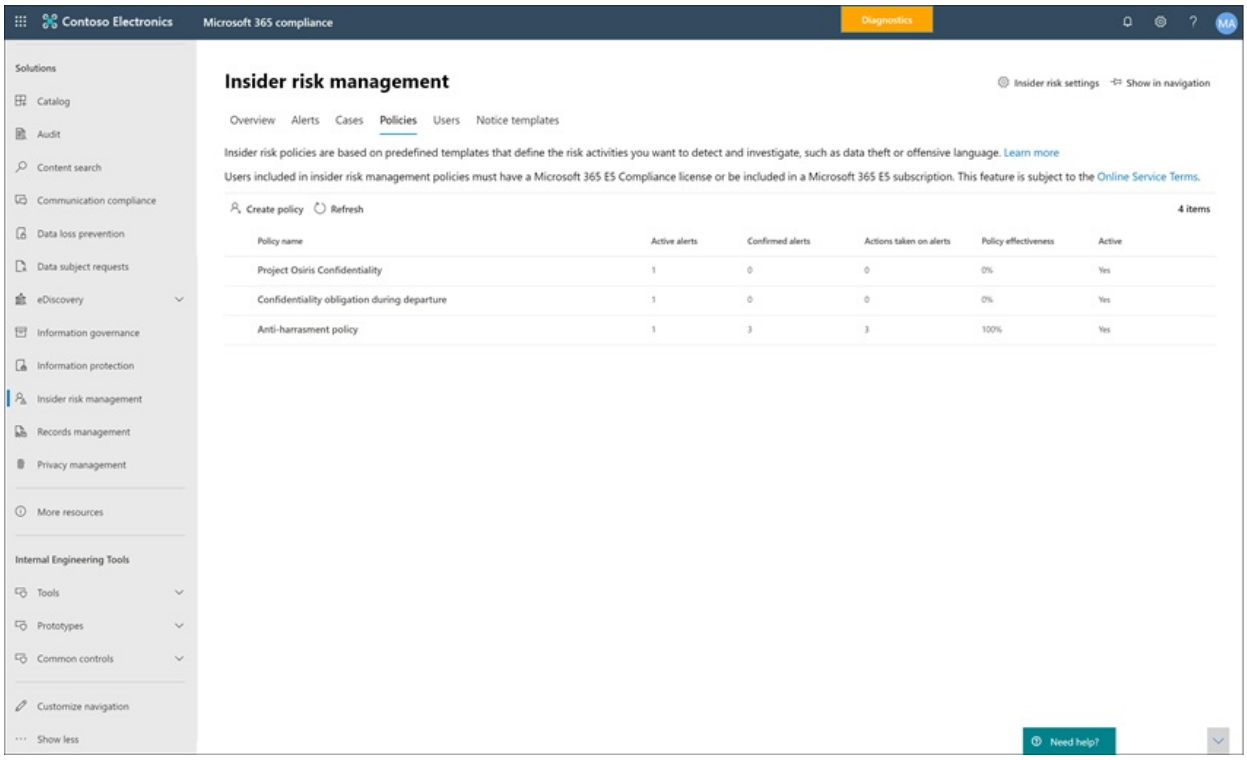


Policies

Insider risk management policies are created using pre-defined templates and policy conditions that define what triggering events and risk indicators are examined in your organization. These conditions include how risk indicators are used for alerts, what users are included in the policy, which services are prioritized, and the monitoring time period.

You can select from the following[policy templates to quickly get started with insider risk management:

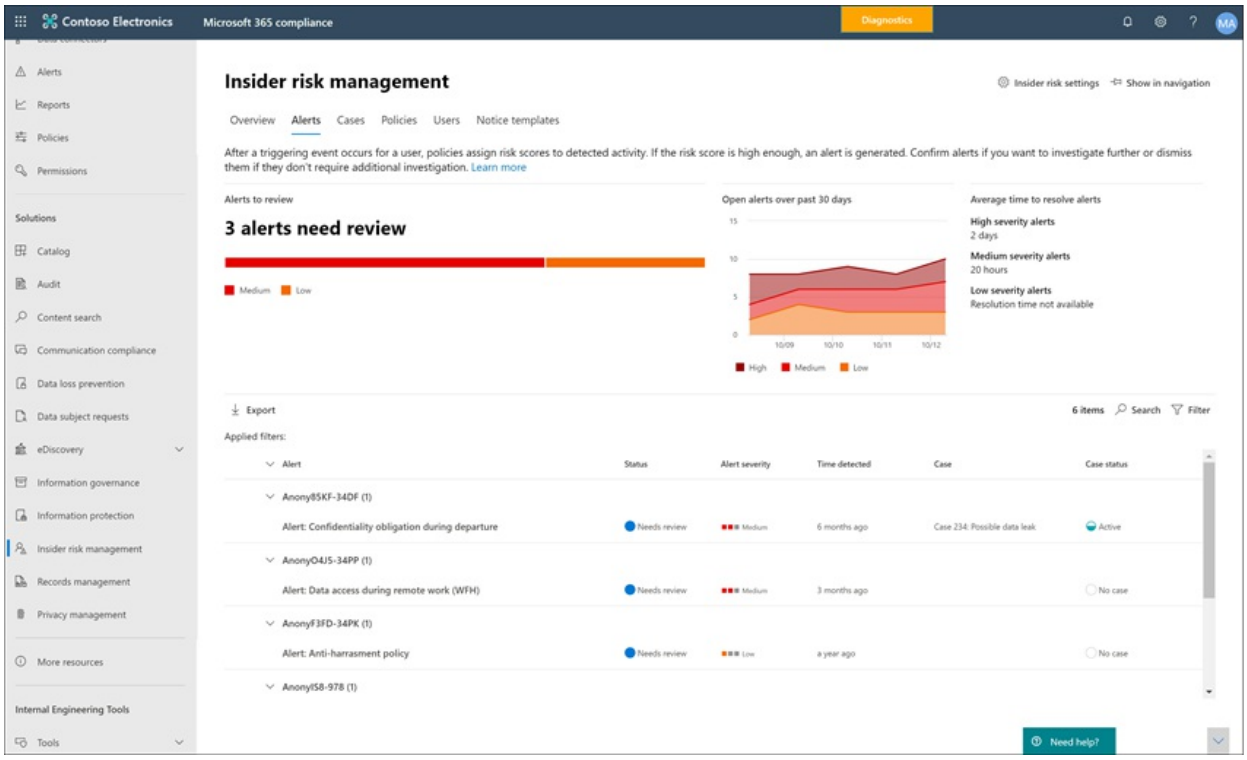
- Data theft by departing users
- General data leaks
- Data leaks by priority users (preview)
- Data leaks by disgruntled users (preview)
- General security policy violations (preview)
- Security policy violations by departing users (preview)
- Security policy violations by priority users (preview)
- Security policy violations by disgruntled users (preview)



Alerts

Alerts are automatically generated by risk indicators that match policy conditions and are displayed in the Alerts dashboard. This dashboard enables a quick view of all alerts needing review, open alerts over time, and alert statistics for your organization. All policy alerts are displayed with the following information to help you quickly identify the status of existing alerts and new alerts that need action:

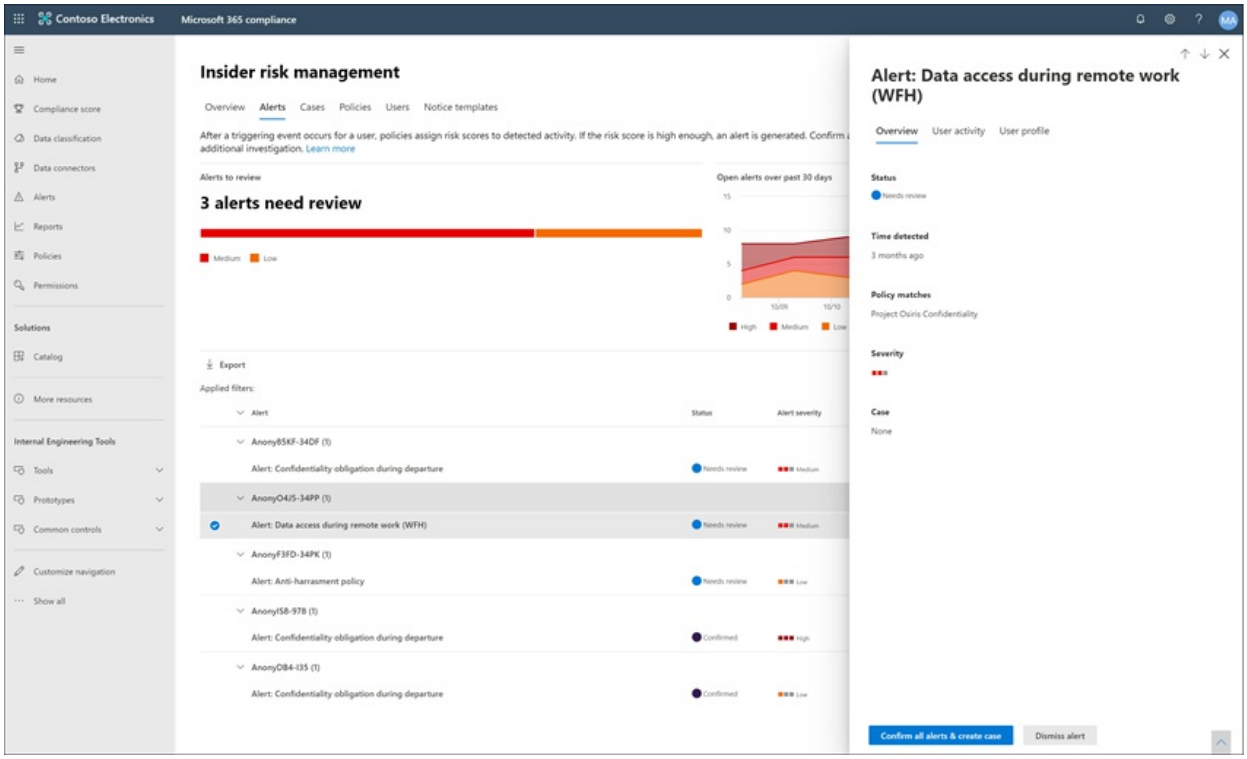
- Status
- Severity
- Time detected
- Case
- Case status



Triage

New user activities that need investigation automatically generate alerts that are assigned a *Needs review* status. Reviewers can quickly identify and review, evaluate, and triage these alerts.

Alerts are resolved by opening a new case, assigning the alert to an existing case, or dismissing the alert. Using alert filters, it's easy to quickly identify alerts by status, severity, or time detected. As part of the triage process, reviewers can view alert details for the activities identified by the policy, view user activity associated with the policy match, see the severity of the alert, and review user profile information.

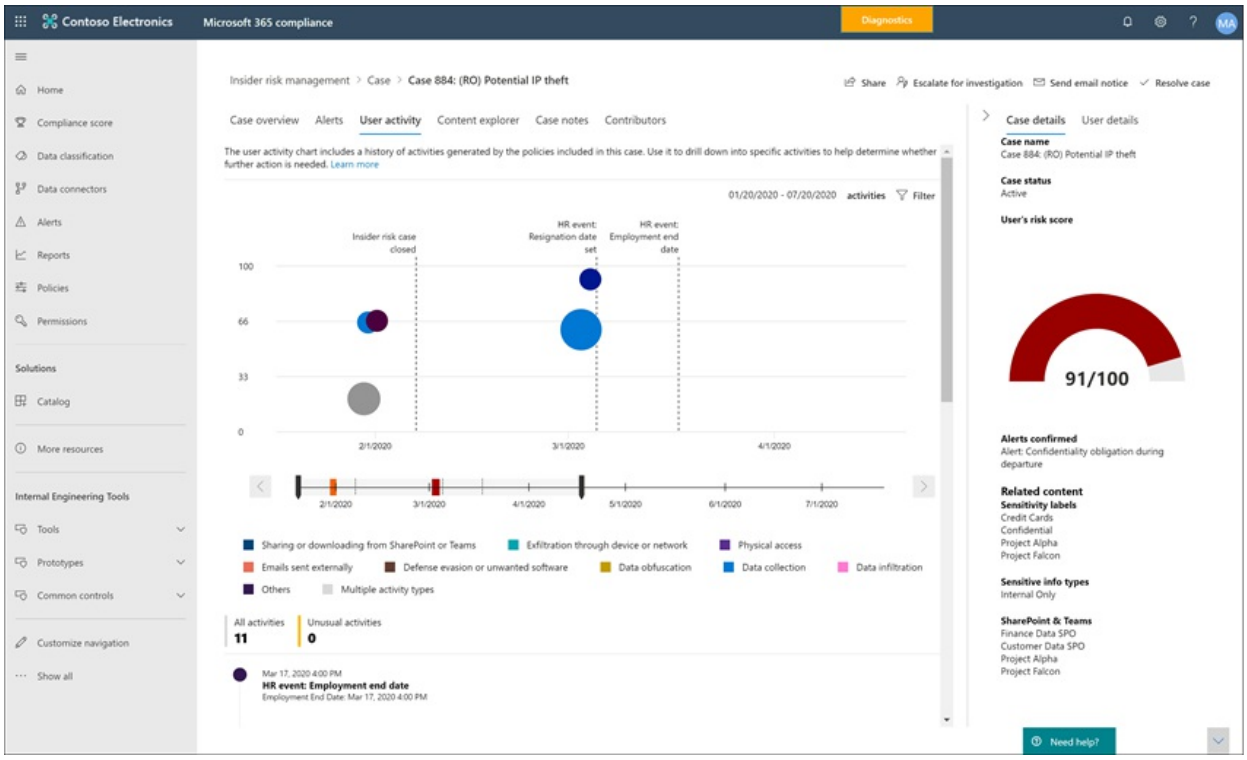


Investigate

Cases are created for alerts that require deeper review and investigation of the activity details and circumstances around the policy match. The **Case dashboard** provides an all-up view of all active cases, open cases over time, and case statistics for your organization. Reviewers can quickly filter cases by status, the date the case was opened, and the date the case was last updated.

Selecting a case on the case dashboard opens the case for investigation and review. This step is the heart of the insider risk management workflow. This area is where risk activities, policy conditions, alerts details, and user details are synthesized into an integrated view for reviewers. The primary investigation tools in this area are:

- **User activity**: User activity is automatically displayed in an interactive chart that plots activities over time and by risk level for current or past risk activities. Reviewers can quickly filter and view the entire risk history for the user and drill into specific activities for more details.
- **Content Explorer**: All data files and email messages associated with alert activities are automatically captured and displayed in the Content Explorer. Reviewers can filter and view files and messages by data source, file type, tags, conversation, and many more attributes.
- **Case notes**: Reviewers can provide notes for a case in the Case Notes section. This list consolidates all notes in a central view and include reviewer and date submitted information.



Action

After cases are investigated, reviewers can quickly act to resolve the case or collaborate with other risk stakeholders in your organization. If users accidentally or inadvertently violate policy conditions, a simple reminder notice can be sent to the user from notice templates you can customize for your organization. These notices may serve as simple reminders or may direct the user to refresher training or guidance to help prevent future risky behavior. For more information, see Insider risk management notice templates.

In the more serious situations, you may need to share the insider risk management case information with other reviewers or services in your organization. Insider risk management is tightly integrated with other Microsoft 365 compliance solutions to help you with end-to-end risk resolution.

- **Advanced eDiscovery**: Escalating a case for investigation allows you to transfer data and management of the case to Advanced eDiscovery in Microsoft 365. Advanced eDiscovery provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. It allows legal teams to manage the entire legal hold notification workflow. To learn more about Advanced eDiscovery cases, see Overview of Advanced eDiscovery in Microsoft 365.
- **ServiceNow (preview)**: ServiceNow is a popular cloud computing platform that helps organizations manage digital workflows for enterprise operations. Insider risk management supports sharing case alerts with your ServiceNow service and allows you to create incidents and change requests related to individual insider risk cases. To learn more about sharing alert information with ServiceNow, see Share a case with ServiceNow.
- **Office 365 Management APIs integration (preview)**: Insider risk management supports exporting alert information to security information and event management (SIEM) services via the Office 365 Management APIs. Having access to alert information in the platform the best fits your organization's risk processes gives you more flexibility in how to act on risk activities. To learn more about exporting alert information with Office 365 Management APIs, see Export alerts.

> **NOTE**
>
> Thank you for your feedback and support during the preview of the ServiceNow connector. We've decided to end the preview of ServiceNow connector and discontinue support in insider risk management on November 30, 2020. We are actively evaluating alternative methods to provide customers with ServiceNow integration in insider risk management.

Scenarios

Insider risk management can help you detect, investigate, and take action to mitigate internal risks in your organization in several common scenarios:

Data theft by departing users

When users leave an organization, either voluntarily or as the result of termination, there is often legitimate concerns that company, customer, and user data are at risk. Users may innocently assume that project data isn't proprietary, or they may be tempted to take company data for personal gain and in violation of company policy and legal standards. Insider risk management policies that use the Data theft by departing users policy template automatically detect activities typically associated with this type of theft. With this policy, you'll automatically receive alerts for suspicious activities associated with data theft by departing users so you can take appropriate investigative actions. Configuring a Microsoft 365 HR connector for your organization is required for this policy template.

Intentional or unintentional leak of sensitive or confidential information

In most cases, users try their best to properly handle sensitive or confidential information. But occasionally users may make mistakes and information is accidentally shared outside your organization or in violation of your information protection policies. In other circumstances, users may intentionally leak or share sensitive and confidential information with malicious intent and for potential personal gain. Insider risk management policies created using the following Data leaks policy templates automatically detect activities typically associated with sharing sensitive or confidential information:

- General data leaks
- Data leaks by priority users (preview)
- Data leaks by disgruntled users (preview)

Intentional or unintentional security policy violations (preview)

Users typically have a large degree of control when managing their devices in the modern workplace. This may include permissions to install or uninstall applications needed in the performance of their duties or the ability to temporarily disable device security features. Whether this activity is inadvertent, accidental, or malicious, this conduct can pose risk to your organization and is important to identify and act to minimize. To help identity these risky security activities, the following insider risk management security policy violation templates scores security risk indicators and uses Microsoft Defender for Endpoint alerts to provide insights for security-related activities:

- General security policy violations (preview)
- Security policy violations by departing users (preview)
- Security policy violations by priority users (preview)
- Security policy violations by disgruntled users (preview)

Policies for users based on position, access level, or risk history (preview)

Users in your organization may have different levels of risk depending on their position, level of access to sensitive information, or risk history. This may include members of your organization's executive leadership team, IT administrators that have extensive data and network access privileges, or users with a past history of risky activities. In these circumstances, closer inspection and more aggressive risk scoring are important to help surface alerts for investigation and quick action. To help identify risky activities for these types of users, you can create priority user groups and create policies from the following policy templates:

- Security policy violations by priority users (preview)

- Data leaks by priority users (preview)

Actions and behaviors by disgruntled users (preview)

Employment stresses events can impact user behavior in several ways that relate to insider risks. These stressors may be a poor performance review, a position demotion, or the user being placement on a performance review plan. Though most users do not respond maliciously to these events, the stress of these actions may result in some users to take actions they may not normally consider during normal circumstances. To help identity these types risky activities, the following insider risk management policy templates use the Microsoft 365 HR connector and starts scoring risk indicators relating to behaviors that may occur near employment stressor events:

- Data leaks by disgruntled users (preview)
- Security policy violations by disgruntled users (preview)

Ready to get started?

- See Plan for insider risk management for how to prepare to enable insider risk management policies in your organization.
- See Get started with insider risk management settings to configure global settings for insider risk policies.
- See Get started with insider risk management to configure prerequisites, create policies, and start receiving alerts.

Plan for insider risk management

2/18/2021 • 6 minutes to read • Edit Online

Before getting started with insider risk management in your organization, there are important planning activities and considerations that should be reviewed by your information technology and compliance management teams. Thoroughly understanding and planning for deployment in the following areas will help ensure that your implementation and use of insider risk management features goes smoothly and is aligned with the best practices for the solution.

Work with stakeholders in your organization

Identify the appropriate stakeholders in your organization to collaborate for taking actions on insider risk management alerts and cases. Some recommended stakeholders to consider including in initial planning and the end-to-end insider risk management workflow are people from the following areas of your organization:

- Information technology
- Compliance
- Privacy
- Security
- Human resources
- Legal

Determine any regional compliance requirements

Different geographic and organizational areas may have compliance and privacy requirements that are different from other areas of your organization. Work with the stakeholders in these areas to ensure they understand the compliance and privacy controls in insider risk management and how they should be used across different areas of your organization. In some scenarios, compliance and privacy requirements might require policies that designate or restrict some stakeholders from investigations and cases based on the case for a user or regulatory or policy requirements for the area.

If you have requirements for specific stakeholders to be involved in case investigations that involve users in certain regions, roles, or divisions, you may want to implement separate (even if identical) insider risk management policies targeting the different regions and populations. This configuration will make it easier for the right stakeholders to triage and manage cases that are relevant to their roles and regions. Additionally, you may want to consider creating processes and policies for regions where investigators and reviewers speak the same language as the users to help streamline the escalation process for insider risk management alerts and cases.

Plan for the review and investigation workflow

Select dedicated stakeholders to monitor and review the alerts and cases on a regular cadence in the Microsoft 365 compliance center. Make sure understand how you will assign different stakeholders to the different role groups available in insider risk management.

Depending on the structure of your compliance management team, you have options to assign users to specific role groups to manage different sets of insider risk management features. To view the **Permissions** tab in the Office 365 Security & Compliance Center and manage role groups, you need to be assigned to the *Organization Management* role group or need to be assigned the *Role Management* role. Choose from these role group options when configuring insider risk management:

ROLE GROUP	ROLE PERMISSIONS
Insider Risk Management	Use this role group to manage insider risk management for your organization in a single group. By adding all user accounts for designated administrators, analysts, and investigators, you can configure insider risk management permissions in a single group. This role group contains all the insider risk management permission roles. This configuration is the easiest way to quickly get started with insider risk management and is a good fit for organizations that do not need separate permissions defined for separate groups of users.
Insider Risk Management Admin	Use this role group to initially configure insider risk management and later to segregate insider risk administrators into a defined group. Users in this role group can create, read, update, and delete insider risk management policies, and global settings.
Insider Risk Management Analysts	Use this group to assign permissions to users that will act as insider risk case analysts. Users in this role group can access to all insider risk management alerts, cases, and notices templates. They cannot access the insider risk Content Explorer.
Insider Risk Management Investigators	Use this group to assign permissions to users that will act as insider risk data investigators. Users in this role group can access to all insider risk management alerts, cases, notices templates, and the Content Explorer for all cases.

Understand requirements and dependencies

Depending on how you plan to implement insider risk management policies, you need to have the proper Microsoft 365 licensing subscriptions and understand and plan for some solution prerequisites.

Licensing: Insider risk management is available as part of wide selection of Microsoft 365 licensing subscriptions. For details, see the Getting started with insider risk management article.

If you don't have an existing Microsoft 365 Enterprise E5 plan and want to try insider risk management, you can add Microsoft 365 to your existing subscription or sign up for a trial of Microsoft 365 Enterprise E5.

Policy template requirements: Depending on the policy template you choose, there are requirements that you need to understand and plan for prior to configuring insider risk management in your organization:

- When using the **Data theft by departing users** template, you must configure a Microsoft 365 HR connector to periodically import resignation and termination date information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.
- When using **Data leaks** templates, you must configure at least one Data Loss Prevention (DLP) policy to define sensitive information in your organization and to receive insider risk alerts for High Severity DLP policy alerts. See the Create, test, and tune a DLP policy article for step-by-step guidance to configure DLP policies for your organization.
- When using **Security policy violation** templates, you must enable Microsoft Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. See the Configure advanced features in Microsoft Defender article for step-by-step guidance to enable Defender for Endpoint integration with insider risk management.
- When using **Disgruntled user** templates, you must configure a Microsoft 365 HR connector to periodically

import performance or demotion status information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.

Test with a small group of users in a production environment

Before enabling the solution broadly in your production environment, you may consider testing the policies with a small set of production users while conducting for the necessary compliance, privacy, and legal reviews in your organization. Evaluating insider risk management in a test environment would require that you generate simulated user actions and other signals to create alerts for triage and cases for processing. This approach isn't practical for most organizations, so testing insider risk management with a small group of users in a production environment is preferred.

Keep the anonymization feature in policy settings enabled to anonymize user display names in the insider risk management console during this testing to maintain privacy within the tool. This setting helps protect the privacy of users that have policy matches and can help promote objectivity in data investigation and analysis reviews for insider risk alerts.

If you don't see any alerts immediately after configuring an insider risk management policy, it may mean the minimum risk threshold has not been met yet. A good way to check if the policy is triggered and working as expected is to see if the user is in-scope for the policy on the **Users** page.

Resources for stakeholders

Share insider risk management documentation with the stakeholders in your organization that are included in your management and remediation workflow:

- Create and manage insider risk policies
- Investigate insider risk alerts
- Take action on insider risk cases
- Review case data with the insider risk Content Explorer
- Create insider risk notice templates

Ready to get started?

Ready to configure insider risk management for your organization? Review the following articles:

- Get started with insider risk management settings to configure global policy settings.
- Get started with insider risk management to configure prerequisites, create policies, and start receiving alerts.

Get started with insider risk management settings

2/18/2021 • 39 minutes to read • Edit Online

Insider risk management settings apply to all insider risk management policies, regardless of the template you chose when creating a policy. Settings are configured using the **Insider risk settings** control located at the top of all insider risk management tabs. These settings control policy components for the following areas:

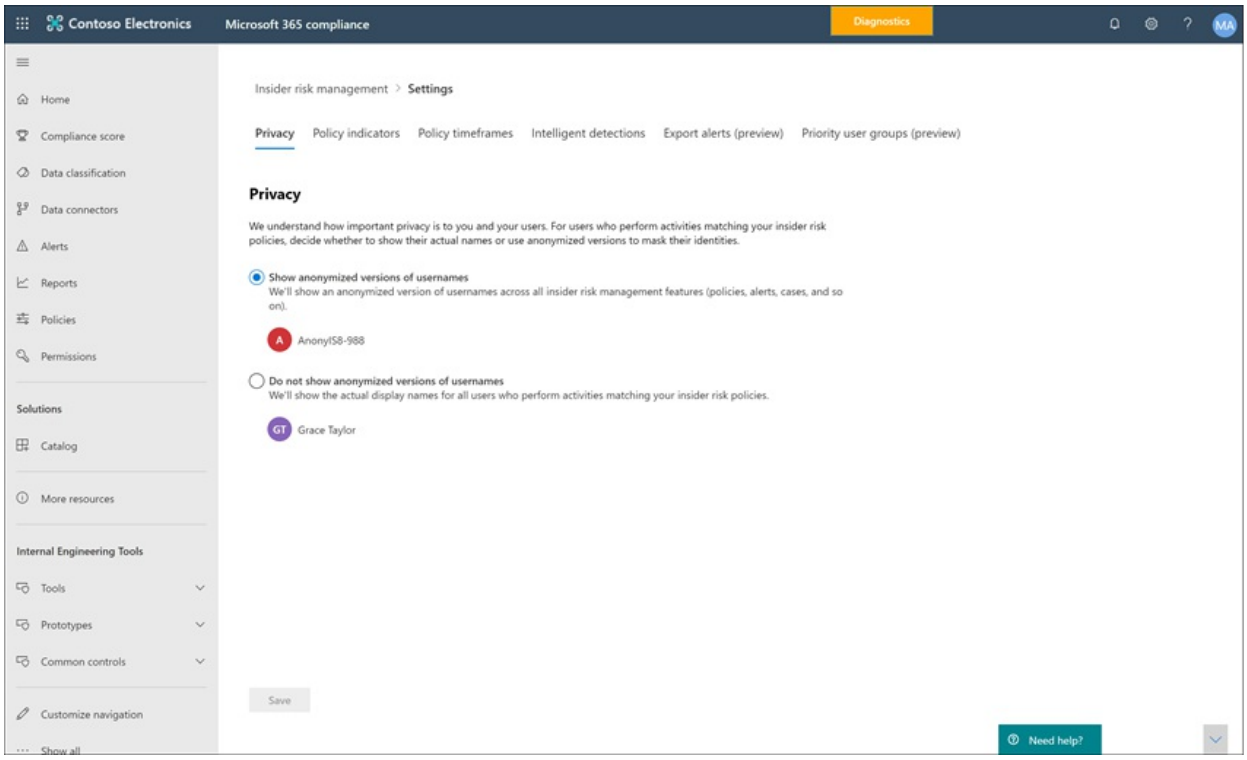
- Privacy
- Indicators
- Policy timelines
- Intelligent detections
- Export alerts (preview)
- Priority user groups (preview)
- Priority physical assets (preview)
- Power Automate flows (preview)
- Microsoft Teams (preview)

Before you get started and create insider risk management policies, it's important to understand these settings and choose setting levels best for the compliance needs for your organization.

Privacy

Protecting the privacy of users that have policy matches is important and can help promote objectivity in data investigation and analysis reviews for insider risk alerts. For users with an insider risk policy match, you can choose one of the following settings:

- **Show anonymized versions of usernames**: Names of users are anonymized to prevent admins, data investigators, and reviewers from seeing who is associated with policy alerts. For example, a user 'Grace Taylor' would appear with a randomized pseudonym such as 'AnonIS8-988' in all areas of the insider risk management experience. Choosing this setting anonymizes all users with current and past policy matches and applies to all policies. User profile information in the insider risk alert and case details will not be available when this option is chosen. However, usernames are displayed when adding new users to existing policies or when assigning users to new policies. If you choose to turn off this setting, usernames will be displayed for all users that have current or past policy matches.
- **Do not show anonymized versions of usernames**: Usernames are displayed for all current and past policy matches for alerts and cases. User profile information (the name, title, alias, and organization or department) is displayed for the user for all insider risk management alerts and cases.



Indicators

Insider risk policy templates define the type of risk activities that you want to detect and investigate. Each policy template is based on specific indicators that correspond to specific triggers and risk activities. All indicators are disabled by default, and you must select one or more policy indicators before configuring an insider risk management policy.

Alerts are triggered by policies when users perform activities related to policy indicators that meet a required threshold. Insider risk management uses two types of indicators:

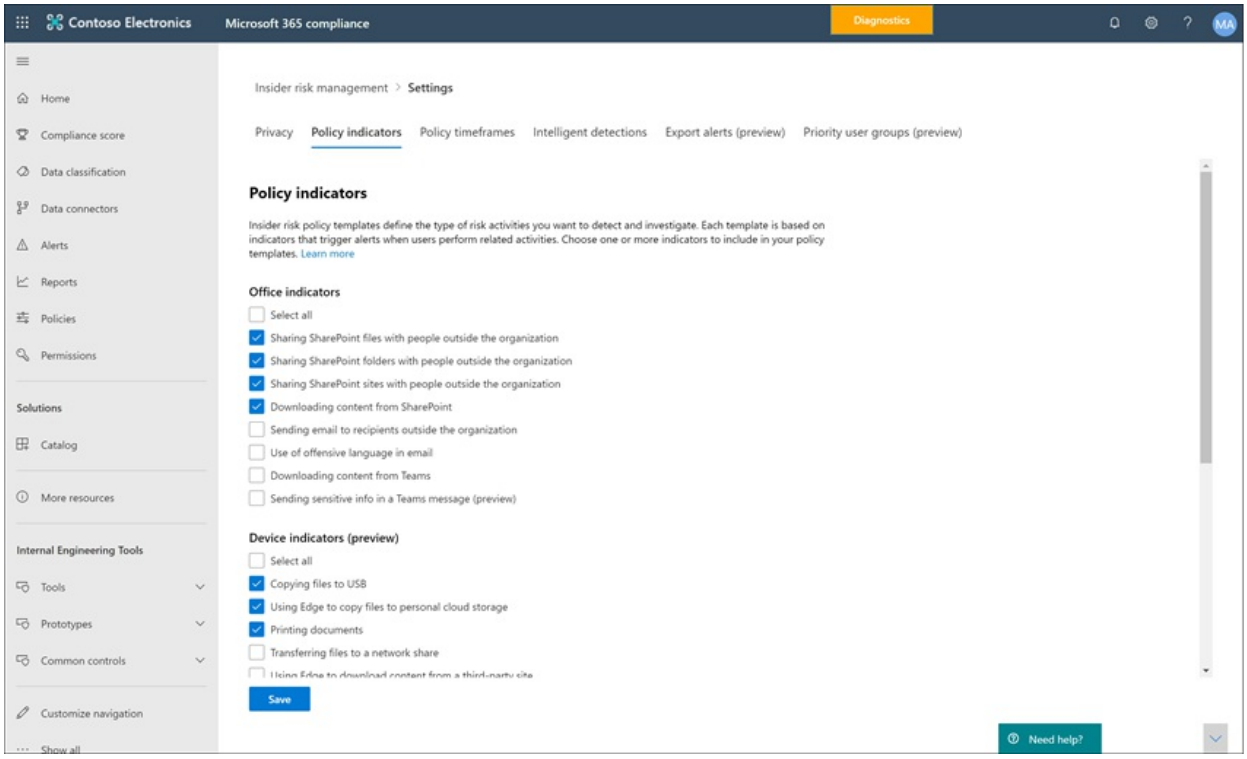
- **Triggering events**: Events that determine if a user is active for an insider risk management policy. If a user is added to an insider risk management policy does not have a triggering event, the user activity is not evaluated by the policy. For example, User A is added to a policy created from the *Data theft by departing users* policy template and the policy and Microsoft 365 HR connector are properly configured. Until User A has a termination date reported by the HR connector, User A activities aren't evaluated by this insider risk management policy for risk. Another example of a triggering event is if a user has a *High* severity DLP policy alert when using *Data leaks* policies.
- **Policy indicators**: Indicators included in insider risk management policies used to determine a risk score for an in-scope user. These policy indicators are only activated after a triggering event occurs for a user. Some examples of policy indicators are when a user copies data to personal cloud storage services or portable storage devices, or if a user shares internal files and folders with unauthorized external parties.

Policy indicators are segmented into the following areas. You can choose the indicators to activate and customize indicator event limits for each indicator level when creating an insider risk policy:

- **Office indicators**: These include policy indicators for SharePoint sites, Teams, and email messaging.
- **Device indicators**: These include policy indicators for activity such as sharing files over the network or with devices. Indicators include activity involving Microsoft Office files, .CSV files, and .PDF files. If you select **Device indicators**, activity is processed only for devices with Windows 10 Build 1809 or higher. For more information on configuring devices for integration with insider risk, see the following Enable device indicators and onboard devices section.
- **Security policy violation indicator**: These include indicators from Microsoft Defender for Endpoint related to unapproved or malicious software installation or bypassing security controls. To receive alerts in

insider risk management, you must have an active Defender for Endpoint license and insider risk integration enabled. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Microsoft Defender for Endpoint.

- **Risk score boosters**: These include raising the risk score for unusual activities or past policy violations. Enabling risk score boosters increase risk scores and the likelihood of alerts for these types of activities. Risk score boosters can only be selected if one or more indicators are selected.



In some cases, you may want to limit the insider risk policy indicators that are applied to insider risk policies in your organization. You can turn off the policy indicators for specific areas by disabling them from all insider risk policies. Triggering events cannot be modified for insider risk policy templates.

To define the insider risk policy indicators that are enabled in all insider risk policies, navigate to **Insider risk settings** > **Indicators** and select one or more policy indicators. The indicators selected on the Indicators settings page cannot be individually configured when creating or editing an insider risk policy in the policy wizard.

> **NOTE**
>
> It may take several hours for new manually-added users to appear in the **Users dashboard**. Activities for the previous 90 days for these users may take up to 24 hours to display. To view activities for manually added users, select the user on the **Users dashboard** and open the **User activity** tab on the details pane.

Enable device indicators and onboard devices

To enable the monitoring of risk activities on devices and include policy indicators for these activities, your devices must meet the following requirements and you must complete the following onboarding steps.

Step 1: Prepare your endpoints

Make sure that the Windows 10 devices that you plan on reporting in insider risk management meet these requirements.

1. Must be running Windows 10 x64 build 1809 or later and must have installed the Windows 10 update (OS Build 17763.1075) from February 20, 2020.
2. All devices must be Azure Active Directory (AAD) joined, or Hybrid Azure AD joined.
3. Install Microsoft Chromium Edge browser on the endpoint device to monitor actions for the cloud upload

activity. See, Download the new Microsoft Edge based on Chromium.

Step 2: Onboarding devices

You must enable device monitoring and onboard your endpoints before you can monitor for insider risk management activities on a device. Both of these actions are done in the Microsoft 365 Compliance portal.

When you want to onboard devices that haven't been onboarded yet, you'll download the appropriate script and deploy as outlined in the following steps.

If you already have devices onboarded into Microsoft Defender for Endpoint, they will already appear in the managed devices list. Follow Step 3: If you have devices onboarded into Microsoft Defender for Endpoint in the next section.

In this deployment scenario, you'll onboard devices that have not been onboarded yet, and you just want to monitor insider risk activities on Windows 10 devices.

1. Open the Microsoft compliance center.
2. Open the Compliance Center settings page and choose **Onboard devices**.

   > **NOTE**
   > While it usually takes about 60 seconds for device onboarding to be enabled, please allow up to 30 minutes before engaging with Microsoft support.

3. Choose **Device management** to open the **Devices** list. The list will be empty until you onboard devices.
4. Choose **Onboarding** to begin the onboarding process.
5. Choose the way you want to deploy to these more devices from the **Deployment method** list and then **download package**.
6. Follow the appropriate procedures in Onboarding tools and methods for Windows 10 machines. This link takes you to a landing page where you can access Microsoft Defender for Endpoint procedures that match the deployment package you selected in step 5:

   - Onboard Windows 10 machines using Group Policy
   - Onboard Windows machines using Microsoft Endpoint Configuration Manager
   - Onboard Windows 10 machines using Mobile Device Management tools
   - Onboard Windows 10 machines using a local script
   - Onboard non-persistent virtual desktop infrastructure (VDI) machines.

Once done and endpoint is onboarded, it should be visible in the devices list and the endpoint will start reporting audit activity logs to insider risk management.

> **NOTE**
> This experience is under license enforcement. Without the required license, data will not be visible or accessible.

Step 3: If you have devices onboarded into Microsoft Defender for Endpoint

If Microsoft Defender for Endpoint is already deployed and there are endpoints reporting in, all these endpoints will appear in the managed devices list. You can continue to onboard new devices into insider risk management to expand coverage by using the Step 2: Onboarding devices section.

1. Open the Microsoft compliance center.
2. Open the Compliance Center settings page and choose **Enable device monitoring**.

3. Choose **Device management** to open the **Devices** list. You should see the list of devices that are already reporting in to Microsoft Defender for Endpoint.
4. Choose **Onboarding** if you need to onboard more devices.
5. Choose the way you want to deploy to these more devices from the **Deployment method** list and then **Download package**.
6. Follow the appropriate procedures in Onboarding tools and methods for Windows 10 machines. This link takes you to a landing page where you can access Microsoft Defender for Endpoint procedures that match the deployment package you selected in step 5:
   - Onboard Windows 10 machines using Group Policy
   - Onboard Windows machines using Microsoft Endpoint Configuration Manager
   - Onboard Windows 10 machines using Mobile Device Management tools
   - Onboard Windows 10 machines using a local script
   - Onboard non-persistent virtual desktop infrastructure (VDI) machines.

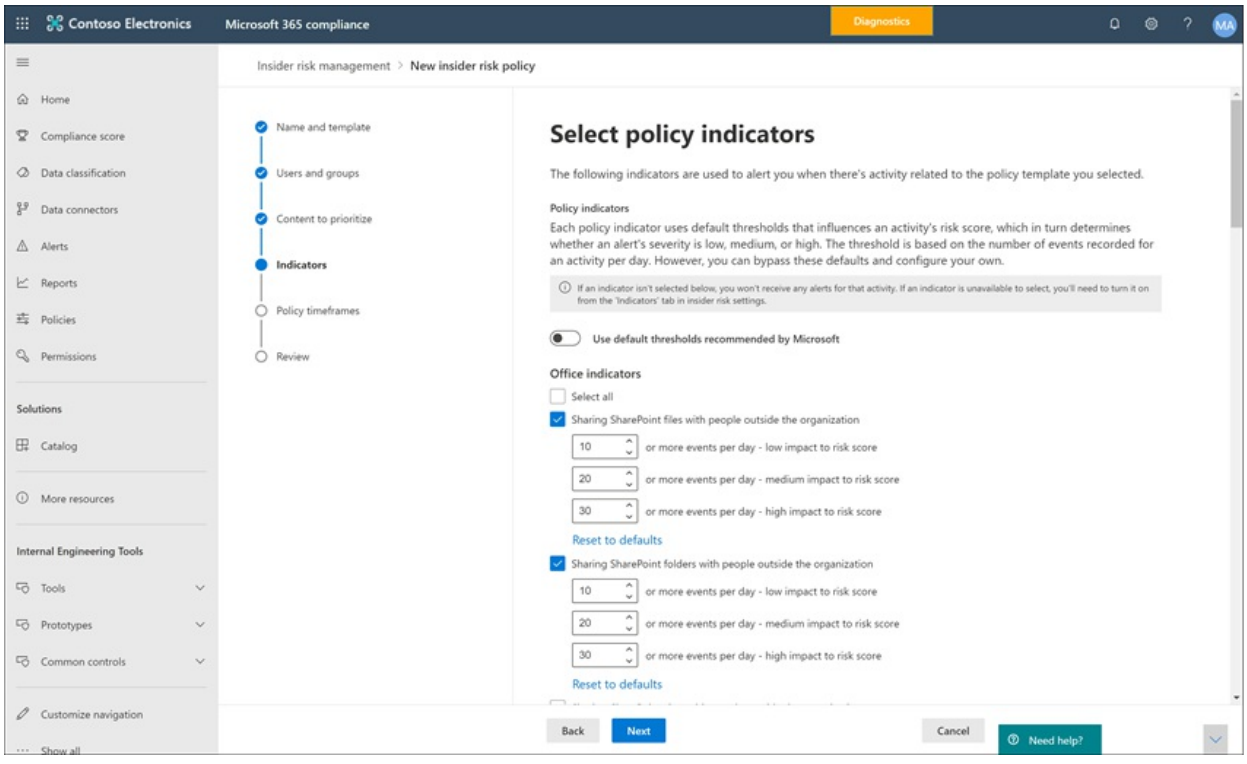
Once done and endpoint is onboarded, it should be visible under the **Devices** table and the endpoint will start reporting audit activity logs to insider risk management.

> **NOTE**
> This experience is under license enforcement. Without the required license, data will not be visible or accessible.

Indicator level settings (preview)

When creating a policy in the policy wizard, you can configure how the daily number of risk events should influence the risk score for insider risk alerts. These indicator settings help you control how the number of occurrences of risk events in your organization should affect the risk score, and consequently the associated alert severity, for these events. If you prefer, you can also choose to keep the default event threshold levels recommended by Microsoft for all enabled indicators.

For example, you decide to enable SharePoint indicators in the insider risk policy settings and to set custom thresholds for SharePoint events when configuring indicators for a new insider risk *Data leaks* policy. While in the insider risk policy wizard, you configure three different daily event levels for each SharePoint indicator to influence the risk score for alerts associated with these events.



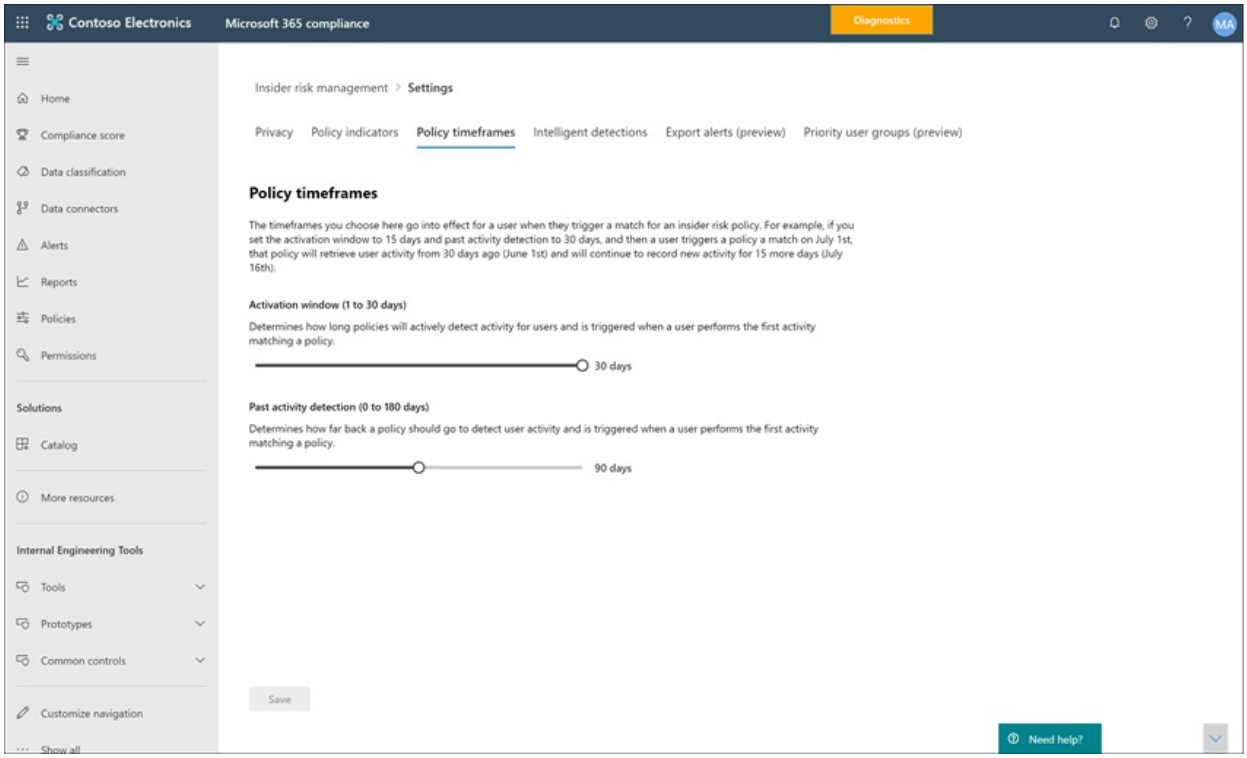
For the first daily event level, you set the threshold at *10 or more events per day* for a lower impact to the risk score for the events, *20 or more events per day* for a medium impact to the risk score for the events, and *30 or more events per day* a higher impact to the risk score for the events. These settings effectively mean:

- If there are 1-9 SharePoint events that take place after triggering event, risk scores are minimally impacted and would tend not to generate an alert.
- If there are 10-19 SharePoint events that take place after a triggering event, the risk score is inherently lower and alert severity levels would tend to be at a low level.
- If there are 20-29 SharePoint events that take place after a triggering, the risk score is inherently higher and alert severity levels would tend to be at a medium level.
- If there are 30 or more SharePoint events that take place after a triggering, the risk score is inherently higher and alert severity levels would tend to be at a high level.

Policy timeframes

Policy timeframes allow you to define past and future review periods that are triggered after policy matches based on events and activities for the insider risk management policy templates. Depending on the policy template you choose, the following policy timeframes are available:

- **Activation window**: Available for all policy templates, the *Activation window* is the defined number of days that the window activates **after** a triggering event. The window activates for 1 to 30 days after a triggering event occurs for any user assigned to the policy. For example, you've configured an insider risk management policy and set the *Activation window* to 30 days. Several months have passed since you configured the policy and a triggering event occurs for one of the users included in the policy. The triggering event activates the *Activation window* and the policy is active for that user for 30 days after the triggering event occurred.
- **Past activity detection**: Available for all policy templates, the *Past activity detection* is the defined number of days that the window activates **before** a triggering event. The window activates for 0 to 180 days before a triggering event occurs for any user assigned to the policy. For example, you've configured an insider risk management policy and set the *Past activity detection* to 90 days. Several months have passed since you configured the policy and a triggering event occurs for one of the users included in the policy. The triggering event activates the *Past activity detection* and the policy gathers historic activities for that user for 90 days prior to the triggering event.



Intelligent detections

Intelligent detection settings help refine how the detections of risky activities are processed for alerts. In certain circumstances, you may need to define files types to ignore or you want to enforce a detection level for files to help define a minimum bar for alerts. Use these settings to control overall alert volume, file type exclusions, and file volume limits.

Anomaly detections

Anomalous detections include settings for file type exclusions and file volume limits.

- **File type exclusions**: To exclude specific file types from all insider risk management policy matching, enter file type extensions separated by commas. For example, to exclude certain types of music files from policy matches you may enter *aac,mp3,wav,wma* in the **File type exclusions** field. Files with these extensions would be ignored by all insider risk management policies.
- **File volume cut-off limit**: To define a minimum file level before activity alerts are reported in insider risk policies, enter the number of files. For example, you would enter '10' if you do not want to generate insider risk alerts when a user downloads 10 files or less, even if the policies consider this activity an anomaly.

Alert volume

User activities detected by insider risk policies are assigned a specific risk score, which in turn determines the alert severity (low, medium, high). By default, we'll generate a certain amount of low, medium, and high severity alerts, but you can increase or decrease the volume to suit your needs. To adjust the volume of alerts for all insider risk management policies, choose one of the following settings:

- **Fewer alerts**: You'll see all high severity alerts, fewer medium severity alerts, and no low severity ones. This setting level means you might miss some true positives.
- **Default volume**: You'll see all high severity alerts and a balanced amount of medium and low severity alerts.
- **More alerts**: You'll see all medium and high severity alerts and most low severity alerts. This setting level might result in more false positives.

Microsoft Defender for Endpoint (preview)

Microsoft Defender for Endpoint is an enterprise endpoint security platform designed to help enterprise networks prevent, detect, investigate, and respond to advanced threats. To have better visibility of security violation in your organization, you can import and filter Defender for Endpoint alerts for activities used in policies created from insider risk management security violation policy templates.

Depending on the types of signals you are interested in, you can choose to import alerts to insider risk management based on the Defender for Endpoint alert triage status. You can define one or more of the following alert triage statuses in the global settings to import:

- Unknown
- New
- In progress
- Resolved

Alerts from Defender for Endpoint are imported daily. Depending on the triage status you choose, you may see multiple user activities for the same alert as the triage status changes in Defender for Endpoint.

For example, if you select *New*, *In progress*, and *Resolved* for this setting, when a Microsoft Defender for Endpoint alert is generated and the status is *New*, an initial alert activity is imported for the user in insider risk. When the Defender for Endpoint triage status changes to *In progress*, a second activity for this alert is imported for the user in insider risk. When the final Defender for Endpoint triage status of *Resolved* is set, a third activity for this alert is imported for the user in insider risk. This functionality allows investigators to follow the progression of the Defender for Endpoint alerts and choose the level of visibility that their investigation

requires.

> **IMPORTANT**
> You'll need to have Microsoft Defender for Endpoint configured in your organization and enable Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Defender for Endpoint.

Domains (preview)

Domain settings help you define risk levels for communications to specific domains. These communications include sharing files, email messages, or downloading content. By specifying domains in these settings, you can increase or decrease the risk scoring for activity that takes place with these domains. For example, to specify contoso.com and sales.wingtiptoys.com as allowed domains, you will enter 'contoso.com sales.wingtiptoys.com' in the **Allowed domains** field.

For each of the following domain settings, you can enter up to 500 domains:

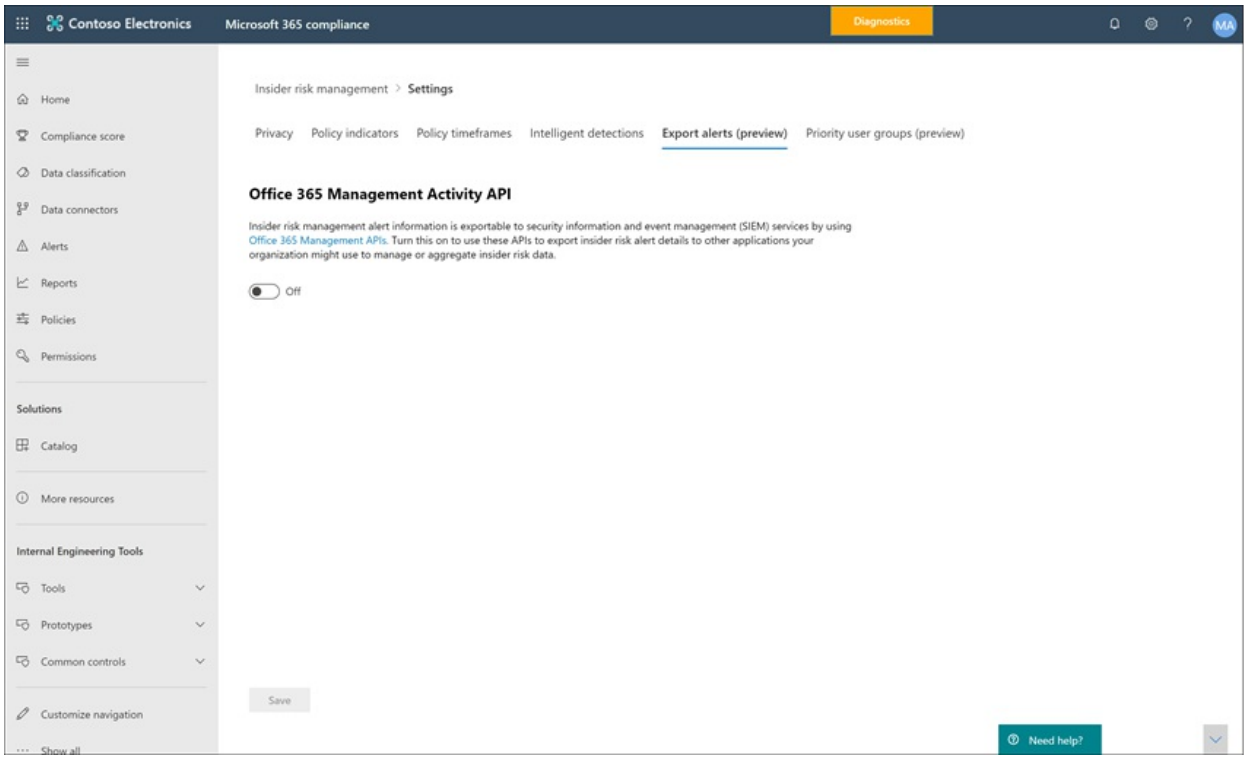
- **Unallowed domains:** By specifying unallowed domains, activity that takes place with these domains will have *higher* risk scores.
- **Allowed domains:** By specifying allowed domains in settings, activity that takes place with these domains will have *lower* risk scores and is treated similarly to how internal organization activity is treated. For example, email activities to these domains are analyzed similarly to how internal email activity is analyzed.
- **Third party domains:** Third party domains are domains used for business purposes at your organization and sensitive content may be stored across these locations. By specifying a third party domain, you can receive alerts for any risky activity on these domains.

Export alerts (preview)

Insider risk management alert information is exportable to security information and event management (SIEM) services via the Office 365 Management Activity API schema. You can use the Office 365 Management Activity APIs to export alert information to other applications your organization may use to manage or aggregate insider risk information.

To use the APIs to review insider risk alert information:

1. Enable Office 365 Management Activity API support in **Insider risk management** > **Settings** > **Export**. By default, this setting is disabled for your Microsoft 365 organization.
2. Filter the common Office 365 audit activities by *SecurityComplianceAlerts*.
3. Filter *SecurityComplianceAlerts* by the *InsiderRiskManagement* category.



Alert information contains information from the security and compliance alert schema and the Office 365 Management Activity API common schema.

The following fields and values are exported for insider risk management alerts for the Security & Compliance alert schema:

ALERT PARAMETER	DESCRIPTION
AlertType	Type of the alert is *Custom*.
AlertId	The GUID of the alert. Insider risk management alerts are mutable. As alert status changes, a new log with the same AlertID is generated. This AlertID can be used to correlate updates for an alert.
Category	The category of the alert is *InsiderRiskManagement*. This category can be used to distinguish from these alerts from other Security & Compliance alerts.
Comments	Default comments for the alert. Values are *New Alert* (logged when an alert is created) and *Alert Updated* (logged when there is an update to an alert). Use the AlertID to correlate updates for an alert.
Data	The data for the alert, includes the unique user ID, user principal name, and date and time (UTC) when user was triggered into a policy.
Name	Policy name for insider risk management policy that generated the alert.
PolicyId	The GUID of the insider risk management policy that triggered the alert.
Severity	The severity of the alert. Values are *High*, *Medium*, or *Low*.

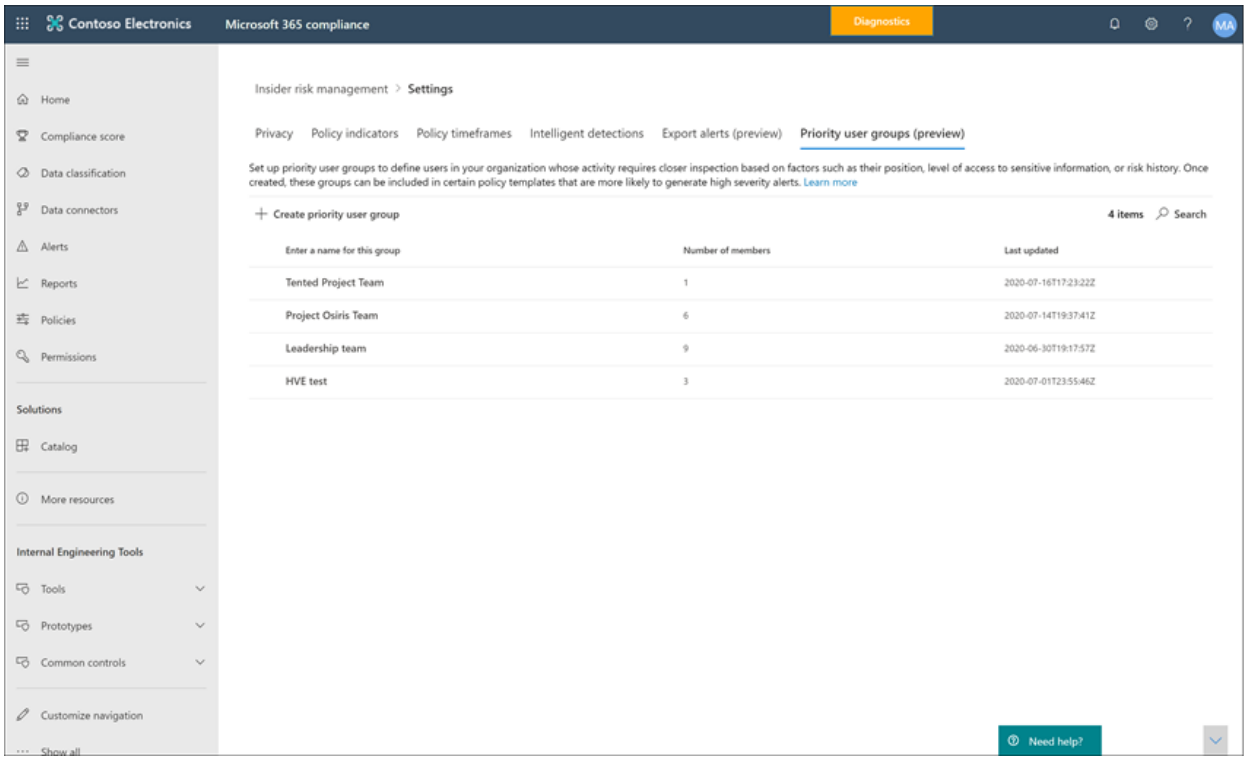
ALERT PARAMETER	DESCRIPTION
Source	The source of the alert. The value is *Office 365 Security & Compliance*.
Status	The status of the alert. Values are *Active* (*Needs Review* in insider risk), *Investigating* (*Confirmed* in insider risk), *Resolved* (*Resolved* in insider risk), *Dismissed* (*Dismissed* in insider risk).
Version	The version of the security and compliance alert schema.

The following fields and values are exported for insider risk management alerts for the Office 365 Management Activity API common schema.

- UserId
- Id
- RecordType
- CreationTime
- Operation
- OrganizationId
- UserType
- UserKey

Priority user groups (preview)

Users in your organization may have different levels of risk depending on their position, level of access to sensitive information, or risk history. Prioritizing the examination and scoring of the activities of these users can help alert you to potential risks that may have higher consequences for your organization. Priority user groups in insider risk management help define the users in your organization that need closer inspection and more sensitive risk scoring. Coupled with the *Security policy violations by priority users* and *Data leaks by priority users* policy templates, users added to a priority user group have an increased likelihood of insider risk alerts and alerts with higher severity levels.



For example, you need to protect against data leaks for a highly confidential project where users have access to sensitive information. You choose to create *Confidential Project Users* priority user group for users in your organization that work on this project. Using the policy wizard and the *Data leaks by priority users* policy template, you create a new policy and assign the *Confidential Project Users* priority users group to the policy. Activities examined by the policy for members of the *Confidential Project Users* priority user group are more sensitive to risk and activities by these users will be more likely to generate an alert and have alerts with higher severity levels.

Create a priority user group

To create a new priority user group, you'll use setting controls in the **Insider risk management** solution in the Microsoft 365 compliance center. To create a priority user group, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group.

Complete the following steps to create a priority user group:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings**.
2. Select the **Priority user groups** tab
3. On the **Priority user groups** tab, select **Create priority user group** to start the group creation wizard.
4. On the **Define group** page, complete the following fields:
   - **Name (required)**: Enter a friendly name for the priority user group. You can't change the name of the priority user group after you complete the wizard.
   - **Description (optional)**: Enter a description for the priority user group.
5. Select **Next** to continue.
6. On the **Choose members** page, select **Choose members** to search and select which mail-enabled user accounts are included in the group or select the **Select all** checkbox to add all users in your organization to the group. Select **Add** to continue or **Cancel** to close without adding any users to the group.
7. Select **Next** to continue.
8. On the **Review** page, review the settings you've chosen for the priority user group. Select **Edit** to change any of the group values or select **Submit** to create and activate the priority user group.
9. On the confirmation page, select **Done** to exit the wizard.

Update a priority user group

To update an existing priority user group, you'll use setting controls in the **Insider risk management** solution in the Microsoft 365 compliance center. To update a priority user group, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group.

Complete the following steps to edit a priority user group:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings**.
2. Select the **Priority user groups** tab
3. Select the priority user group you want to edit and select **Edit group**.
4. On the **Define group** page, update the Description field if needed. You can't update the name of the priority user group. Select **Next** to continue.
5. On the **Choose members** page, add new members to the group using the **Choose members** control. To remove a user from the group, select the 'X' next to the user you wish to remove. Select **Next** to continue.
6. On the **Review** page, review the update settings you've chosen for the priority user group. Select **Edit** to change any of the group values or select **Submit** to update the priority user group.
7. On the confirmation page, select **Done** to exit the wizard.

Delete a priority user group

To delete an existing priority user group, you'll use setting controls in the **Insider risk management** solution in the Microsoft 365 compliance center. To delete a priority user group, you must be a member of the *Insider*

Risk Management or *Insider Risk Management Admin* role group.

> **IMPORTANT**
> Deleting a priority user group will remove it from any active policy to which it is assigned. If you delete a priority user group that is assigned to an active policy, the policy will not contain any in-scope users and will effectively be idle and will not create alerts.

Complete the following steps to delete a priority user group:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings**.
2. Select the **Priority user groups** tab
3. Select the priority user group you want to edit and select **Delete** from the dashboard menu.
4. On the **Delete** dialog, select **Yes** to delete the priority user group or select **Cancel** to return to the dashboard.

Priority physical assets (preview)

Identifying access to priority physical assets and correlating access activity to user events is an important component of your compliance infrastructure. These physical assets represent priority locations in your organization, such as company buildings, data centers, or server rooms. Insider risk activities may be associated with users working unusual hours, attempting to access these unauthorized sensitive or secure areas, and requests for access to high-level areas without legitimate needs.

With priority physical assets enabled and the Physical badging data connector configured, insider risk management integrates signals from your physical control and access systems with other user risk activities. By examining patterns of behavior across physical access systems and correlating these activities with other insider risk events, insider risk management can help compliance investigators and analysts make more informed response decisions for alerts. Access to priority physical assets are scored and identified in insights differently from access to non-priority assets.

For example, your organization has a badging system for users that monitors and approves physical access to normal working and sensitive project areas. You have several users working on a sensitive project and these users will return to other areas of your organization when the project is completed. As the sensitive project nears completion, you want to make sure that the project work remains confidential and that access to the project areas is tightly controlled.

You choose to enable the Physical badging data connector in Microsoft 365 to import access information from your physical badging system and specify priority physical assets in insider risk management. By importing information from your badging system and correlating physical access information with other risk activities identified in insider risk management, you notice that one of the users on the project is accessing the project offices after normal working hours and is also exporting large amounts of data to a personal cloud storage service from their normal work area. This physical access activity associated with the online activity may point to possible data theft and compliance investigators and analysts can take appropriate actions as dictated by the circumstances for this user.

Configure priority physical assets

To configure priority physical assets, you'll configure the Physical badging connector and use setting controls in the **Insider risk management** solution in the Microsoft 365 compliance center. To configure priority physical assets, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin role group*.

Complete the following steps to configure priority physical assets:

1. Follow the configuration steps for insider risk management in the Getting started with insider risk management article. In Step 3, make sure you configure the Physical badging connector.

> **IMPORTANT**
> For insider risk management policies to use and correlate signal data related to departing and terminated users with event data from your physical control and access platforms, you must also configure the Microsoft 365 HR connector. If you enable the Physical badging connector without enabling the Microsoft 365 HR connector, insider risk management policies will only process events for physical access activities for users in your organization.

2. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Priority physical assets**.
3. On the **Priority physical assets** page, you can either manually add the physical asset IDs you want to monitor for the asset events imported by the Physical badging connector or import a .CSV file of all physical assets IDs imported by the Physical badging connector: a) To manually add physical assets IDs, choose **Add priority physical assets**, enter a physical asset ID, then select **Add**. Enter other physical asset IDs and then select **Add priority physical assets** to save all the assets entered. b) To add a list of physical asset IDs from a .CSV file, choose **Import priority physical assets**. From the file explorer dialog, select the .CSV file you wish to import, then select **Open**. The physical asset IDs from the .CSV files are added to the list.
4. Navigate to the **Policy indicators** tab in Settings.
5. On the **Policy indicators** page, navigate to the **Physical access indicators** section and select the checkbox for **Physical access after termination or failed access to sensitive asset**.
6. Select **Save** to configure and exit.

Delete a priority physical asset

To delete an existing priority physical asset, you'll use setting controls in the Insider risk management solution in the Microsoft 365 compliance center. To delete a priority physical asset, you must be a member of the Insider Risk Management or Insider Risk Management Admin role group.

> **IMPORTANT**
> Deleting a priority physical asset removes it from examination by any active policy to which it was previously included. Alerts generated by activities associated with the priority physical asset aren't deleted.

Complete the following steps to delete a priority physical asset:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Priority physical assets**.
2. On the **Priority physical assets** page, select the asset you want to delete.
3. Select **Delete** on the action menu to delete the asset.

Power Automate flows (preview)

Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or created manually, you can automate common tasks associated with these applications and services. When you enable Power Automate flows for insider risk management, you can automate important tasks for cases and users. You can configure Power Automate flows to retrieve user, alert, and case information and share this information with stakeholders and other applications, as well as automate actions in insider risk management, such as posting to case notes. Power Automate flows are applicable for cases and any user in scope for a policy.

Customers with Microsoft 365 subscriptions that include insider risk management do not need additional Power

Automate licenses to use the recommended insider risk management Power Automate templates. These templates can be customized to support your organization and cover core insider risk management scenarios. If you choose to use premium Power Automate features in these templates, create a custom template using the Microsoft 365 compliance connector, or use Power Automate templates for other compliance areas in Microsoft 365, you may need more Power Automate licenses.

The following Power Automate templates are provided to customers to support process automation for insider risk management users and cases:

- **Notify users when they're added to an insider risk policy**: This template is for organizations that have internal policies, privacy, or regulatory requirements that users must be notified when they are subject to insider risk management policies. When this flow is configured and selected for a user in the users page, users and their managers are sent an email message when the user is added to an insider risk management policy. This template also supports updating a SharePoint list hosted on a SharePoint site to help track notification message details like date/time and the message recipient. If you've chosen to anonymize users in **Privacy settings**, flows created from this template will not function as intended so that user privacy is maintained. Power Automate flows using this template are available on the **Users dashboard**.

- **Request information from HR or business about a user in an insider risk case**: When acting on a case, insider risk analysts and investigators may need to consult with HR or other stakeholders to understand the context of the case activities. When this flow is configured and selected for a case, analysts and investigators send an email message to HR and business stakeholders configured for this flow. Each recipient is sent a message with pre-configured or customizable response options. When recipients select a response option, the response is recorded as a case note and includes recipient and date/time information. If you've chosen to anonymize users in **Privacy settings**, flows created from this template will not function as intended so that user privacy is maintained. Power Automate flows using this template are available on the **Cases dashboard**.

- **Notify manager when a user has an insider risk alert**: Some organizations may need to have immediate management notification when a user has an insider risk management alert. When this flow is configured and selected, the manager for the case user is sent an email message with the following information about all case alerts:

  - Applicable policy for the alert
  - Date/Time of the alert
  - Severity level of the alert

  The flow automatically updates the case notes that the message was sent and that the flow was activated. If you've chosen to anonymize users in **Privacy settings**, flows created from this template will not function as intended so that user privacy is maintained. Power Automate flows using this template are available on the **Cases dashboard**.

- **Add calendar reminder to follow up on an insider risk case**: This template allows risk investigators and analysts to add calendar reminders for cases to their Office 365 Outlook calendar. This flow eliminates the need for users to exit or switch out of the insider risk management workflow when processing cases and triaging alerts. When this flow is configured and selected, a reminder is added to Office 365 Outlook calendar for the user running the flow. Power Automate flows using this template are available on the **Cases dashboard**.

- **Create record for insider risk case in ServiceNow**: This template is for organizations that want to use their ServiceNow solution to track insider risk management cases. When in a case, insider risk analysts and investigators can create a record for the case in ServiceNow. You can customize this template to populate selected fields in ServiceNow based on your organization's requirements. Power Automate flows using this template are available on the **Cases dashboard**. For more information on available ServiceNow fields, see the ServiceNow Connector reference article.

Create a Power Automate flow from insider risk management template

To create a Power Automate flow from a recommended insider risk management template, you'll use the settings controls in the **Insider risk management** solution in the Microsoft 365 compliance center or the **Manage Power Automate flows** option from the **Automate** control when working directly in the **Cases** or **Users dashboards**.

To create a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group. To create a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one insider risk management role group.

Complete the following steps to create a Power Automate flow from a recommended insider risk management template:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Power Automate flows**. You can also access from the **Cases** or **Users dashboards** pages by choosing **Automate** > **Manage Power Automate flows**.
2. On the **Power Automate flows** page, select a recommended template from the **Insider risk management templates you may like** section on the page.
3. The flow lists the embedded connections needed for the flow and will note if the connection statuses are available. If needed, update any connections that aren't displayed as available. Select **Continue**.
4. By default, the recommended flows are pre-configured with the recommended insider risk management and Microsoft 365 service data fields required to complete the assigned task for the flow. If needed, customize the flow components by using the **Show advanced options** control and configuring the available properties for the flow component.
5. If needed, add any other steps to the flow by selecting the **New step** button. In most cases, this should not be needed for the recommended default templates.
6. Select **Save draft** to save the flow for further configuration or select **Save** to complete the configuration for the flow.
7. Select **Close** to return to the **Power Automate flow** page. The new template will be listed as a flow on the **My flows** tabs and is automatically available from the **Automate** dropdown control when working with insider risk management cases for the user creating the flow.

> **IMPORTANT**
> If other users in your organization need access to the flow, the flow must be shared.

Create a custom Power Automate flow for insider risk management

Some processes and workflows for your organization may be outside of the recommended insider risk management flow templates and you may have the need to create custom Power Automate flows for insider risk management areas. Power Automate flows are flexible and support extensive customization, but there are steps that need to be taken to integrate with insider risk management features.

Complete the following steps to create a custom Power Automate template for insider risk management:

1. **Check your Power Automate flow license**: To create customized Power Automate flows that use insider risk management triggers, you'll need a Power Automate license. The recommended insider risk management flow templates do not require extra licensing and are included as part of your insider risk management license.
2. **Create an automated flow**: Create a flow that performs one or more tasks after it's triggered by an insider risk management event. For details on how to create an automated flow, see Create a flow in Power Automate.
3. **Select the Microsoft 365 compliance connector**: Search for and select the Microsoft 365 compliance connector. This connector enables insider risk management triggers and actions. For more information on

connectors, see the Connector reference overview article.

4. **Choose insider risk management triggers for your flow**: Insider risk management has two triggers available for custom Power Automate flows:
   - **For a selected insider risk management case**: Flows with this trigger can be selected from the insider risk management Cases dashboard page.
   - **For a selected insider risk management user**: Flows with this trigger can be selected from the insider risk management Users dashboard page.
5. Choose insider risk management actions for your flow: You can choose from several actions for insider risk management to include in your custom flow:
   - Get insider risk management alert
   - Get insider risk management case
   - Get insider risk management user
   - Get insider risk management alerts for a case
   - Add insider risk management case note

Share a Power Automate flow

By default, Power Automate flows created by a user are only available to that user. For other insider risk management users to have access and use a flow, the flow must be shared by the flow creator. To share a flow, you'll use the settings controls in the **Insider risk management solution** in the Microsoft 365 compliance center or the **Manage Power Automate flows** option from the Automate control when working directly in the **Cases** or **Users dashboard** pages. Once you have shared a flow, everyone who it has been shared with can access the flow in the **Automate** control dropdown in the **Case** and **User dashboards**.

To share a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group. To share a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one insider risk management role group.

Complete the following steps to share a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Power Automate flows**. You can also access from the **Cases** or **Users dashboards** pages by choosing **Automate** > **Manage Power Automate flows**.
2. On the **Power Automate flows** page, select the **My flows** or **Team flows** tab.
3. Select the flow to share, then select **Share** from the flow options menu.
4. On the flow sharing page, enter the name of the user or group you want to add as an owner for the flow.
5. On the **Connection Used** dialog, select **OK** to acknowledge that the added user or group will have full access to the flow.

Edit a Power Automate flow

To edit a flow, you'll use the settings controls in the **Insider risk management** solution in the Microsoft 365 compliance center or the **Manage Power Automate flows** option from the **Automate** control when working directly in the **Cases** or **Users dashboards**.

To edit a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group. To edit a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one insider risk management role group.

Complete the following steps to edit a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Power Automate flows**. You can also access from the **Cases** or **Users dashboards** pages by choosing **Automate** > **Manage Power Automate flows**.
2. On the **Power Automate flows** page, select a flow to edit and select **Edit** from the flow control menu.

3. Select the **ellipsis** > **Settings** to change a flow component setting or **ellipsis** > **Delete** to delete a flow component.
4. Select **Save** and then **Close** to complete editing the flow.

Delete a Power Automate flow

To delete a flow, you'll use the settings controls in the **Insider risk management** solution in the Microsoft 365 compliance center or the **Manage Power Automate flows** option from the **Automate** control when working directly in the **Cases** or **Users dashboards**. When a flow is deleted, it is removed as an option for all users.

To delete a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group. To delete a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one insider risk management role group.

Complete the following steps to delete a Power Automate flow:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** > **Power Automate flows**. You can also access from the **Cases** or **Users dashboards** pages by choosing **Automate** > **Manage Power Automate flows**.
2. On the **Power Automate flows** page, select a flow to delete and select **Delete** from the flow control menu.
3. On the deletion confirmation dialog, select **Delete** to remove the flow or select **Cancel** to exit the deletion action.

Microsoft Teams (preview)

Compliance analysts and investigators can easily use Microsoft Teams for collaboration on insider risk management cases. They can coordinate and communicate with other stakeholders in Microsoft Teams to:

- Coordinate and review response activities for cases in private Teams channels
- Securely share and store files and evidence related to individual cases
- Track and review response activities by analysts and investigators

After Microsoft Teams is enabled for insider risk management, a dedicated Microsoft Teams team is created every time an alert is confirmed and a case is created. By default, the team automatically includes all members of the *Insider Risk Management*, *Insider Risk Management Analysts*, and *Insider Risk Management Investigators* role groups (up to 100 initial users). Additional organization contributors may be added to the team after it is created and as appropriate. For existing cases created before enabling Microsoft Teams, analysts and investigators can choose to create a new Microsoft Teams team when working in a case if needed. Once you resolve the associated case in insider risk management, the team is automatically archived (moved to hidden and read-only).

For more information on how to use teams and channels in Microsoft Teams, see Overview of teams and channels in Microsoft Teams.

Enabling Microsoft Teams support for cases is quick and easy to configure. To enable Microsoft Teams for insider risk management, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** > **Insider risk settings**.
2. Select the **Microsoft Teams** tab.
3. Enable Microsoft Teams integration for insider risk management.
4. Select **Save** to configure and exit.

Create a Microsoft Teams team for existing cases

If you enable Microsoft Teams support for insider risk management after you have existing cases, you'll need to manually create a team for each case as needed. After enabling Microsoft Teams support in insider risk management settings, new cases will automatically create a new Microsoft Teams team.

Users need permission to create Microsoft 365 groups in your organization to create a Microsoft Teams team from a case. For more information about managing permissions for Microsoft 365 Groups, see Manage who can create Microsoft 365 Groups.

To create a team for a case, you'll use the Create Microsoft Team control when working directly in an existing case. Complete the following steps to create a new team:

1. In the Microsoft 365 compliance center, go to **Insider risk management** > **Cases** and select an existing case.
2. On the case action menu, select **Create Microsoft Team**.
3. In the **Team name** field, enter a name for the new Microsoft Teams team.
4. Select **Create Microsoft team** and then select **Close**.

Depending on the number of users assigned to insider risk management role groups, it may take 15 minutes for all investigators and analysts to be added to the Microsoft Teams team for a case.

Get started with insider risk management

2/18/2021 • 14 minutes to read • Edit Online

Use insider risk management policies to identify risky activities and management tools to act on risk alerts in your organization. Complete the following steps to set up prerequisites and configure an insider risk management policy.

> **IMPORTANT**
>
> The Microsoft 365 insider risk management solution provides a tenant level option to help customers facilitate internal governance at the user level. Tenant level administrators can set up permissions to provide access to this solution for members of your organization and set up data connectors in the Microsoft 365 compliance center to import relevant data to support user level identification of potentially risky activity. Customers acknowledge insights related to the individual user's behavior, character, or performance materially related to employment can be calculated by the administrator and made available to others in the organization. In addition, customers acknowledge that they must conduct their own full investigation related to the individual user's behavior, character, or performance materially related to employment, and not just rely on insights from the insider risk management service. Customers are solely responsible for using the Microsoft 365 insider risk management service, and any associated feature or service in compliance with all applicable laws, including laws relating to individual user identification and any remediation actions.

For more information about how insider risk policies can help you manage risk in your organization, see Insider risk management in Microsoft 365.

Subscriptions and licensing

Before you get started with insider risk management, you should confirm your Microsoft 365 subscription and any add-ons. To access and use insider risk management, your organization must have one of the following subscriptions or add-ons:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Compliance add-on
- Microsoft 365 E3 subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Compliance add-on
- Microsoft 365 A3 subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Microsoft 365 G5 subscription (paid or trial version)
- Microsoft 365 G3 subscription + the Microsoft 365 G5 Compliance add-on
- Microsoft 365 G3 subscription + the Microsoft 365 G5 Insider Risk Management add-on
- Office 365 E3 subscription + Enterprise Mobility and Security E3 + the Microsoft 365 E5 Compliance add-on

Users included in insider risk management policies must be assigned one of the licenses above.

If you don't have an existing Microsoft 365 Enterprise E5 plan and want to try insider risk management, you can add Microsoft 365 to your existing subscription or sign up for a trial of Microsoft 365 Enterprise E5.

Step 1: Enable permissions for insider risk management

IMPORTANT

After configuring your role groups, it may take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

There are four roles groups used to configure permissions to manage insider risk management features. To continue with these configuration steps, your tenant administrators must first assign you to the **Insider Risk Management** or **Insider Risk Management Admin** role group. To access and manage insider risk management features after initial configuration, users must be a member of at least one insider risk management role group.

Depending on the structure of your compliance management team, you have options to assign users to specific role groups to manage different sets of insider risk management features. To view the **Permissions** tab in the Office 365 Security & Compliance Center and manage role groups, you need to be assigned to the *Organization Management* role group or need to be assigned the *Role Management* role. Choose from these role group options when configuring insider risk management:

ROLE GROUP	ROLE PERMISSIONS
Insider Risk Management	Use this role group to manage insider risk management for your organization in a single group. By adding all user accounts for designated administrators, analysts, and investigators, you can configure insider risk management permissions in a single group. This role group contains all the insider risk management permission roles. This configuration is the easiest way to quickly get started with insider risk management and is a good fit for organizations that do not need separate permissions defined for separate groups of users.
Insider Risk Management Admin	Use this role group to initially configure insider risk management and later to segregate insider risk administrators into a defined group. Users in this role group can create, read, update, and delete insider risk management policies, and global settings.
Insider Risk Management Analysts	Use this group to assign permissions to users that will act as insider risk case analysts. Users in this role group can access all insider risk management alerts, cases, and notices templates. They cannot access the insider risk Content Explorer.
Insider Risk Management Investigators	Use this group to assign permissions to users that will act as insider risk data investigators. Users in this role group can access all insider risk management alerts, cases, notices templates, and the Content Explorer.

NOTE

These role groups are currently not supported on Privileged Identity Management (PIM). To learn more about PIM, see Assign Azure AD roles in Privileged Identity Management.

Add users to an insider risk management role group

Complete the following steps to add users to an insider risk management role group:

1. Sign into https://protection.office.com/permissions using credentials for an admin account in your

Microsoft 365 organization.

2. In the Security & Compliance Center, go to **Permissions**. Select the link to view and manage roles in Office 365.
3. Select the insider risk management role group you want to add users to, then select **Edit role group**.
4. Select **Choose members** from the left navigation pane, then select **Edit**.
5. Select **Add** and then select the checkbox for all users you want to add to the role group.
6. Select **Add**, then select **Done**.
7. Select **Save** to add the users to the role group. Select **Close** to complete the steps.

Step 2: Enable the audit log

Insider risk management uses audit logs for user insights and activities configured in policies. The audit logs are a summary of all activities associated with an insider risk management policy or anytime a policy is changed.

For step-by-step instructions to turn on auditing, see Turn audit log search on or off. After you turn on auditing, a message is displayed that says the audit log is being prepared and that you can run a search in a couple of hours after the preparation is complete. You only have to do this action once. For more information about the using the audit log, see Search the audit log.

Step 3: Configure prerequisites for templates

Most insider risk management templates have prerequisites that must be configured for policy indicators to generate relevant activity alerts. Configure the appropriate prerequisites depending on the policies you plan to configure for your organization.

Configure Microsoft 365 HR connector

Insider risk management supports importing user and log data imported from 3rd-party risk management and human resources platforms. The Microsoft 365 Human Resources (HR) data connector allows you to pull in human resources data from CSV files, including user termination dates, last employment dates, performance improvement plan notifications, performance review actions, and job level change status. This data helps drive alert indicators in insider risk management policies and is an important part of configuring full risk management coverage in your organization. If you configure more than one HR connector for your organization, insider risk management will automatically pull indicators from all HR connectors.

The Microsoft 365 HR connector is required when using the following policy templates:

- Departing user data theft
- Security policy violations by departing users
- Security policy violations by disgruntled users
- Data leaks by disgruntled users

See the Set up a connector to import HR data article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization. After you've configured the HR connector, return to these configuration steps.

Configure Data Loss Prevention (DLP) policies

Insider risk management supports using DLP policies to help identify the intentional or accidental exposure of sensitive information to unwanted parties for High severity level DLP alerts. When configuring an insider risk management policy with any of the **Data leaks** templates, you must assign a specific DLP policy to the policy.

DLP policies help identify users to activate risk scoring in insider risk management for high severity DLP alerts

for sensitive information and are an important part of configuring full risk management coverage in your organization. For more information about insider risk management and DLP policy integration and planning considerations, see Insider risk management policies.

> **IMPORTANT**
>
> Make sure you've completed the following:
>
> - You understand and properly configure the in-scope users in both the DLP and insider risk management policies to produce the policy coverage you expect.
> - Make sure the **Incident reports** setting in the DLP policy for insider risk management used with these templates are configured for *High* severity level alerts. Insider risk management alerts won't be generated from DLP policies with the **Incident reports** field set at *Low* or *Medium*.

A DLP policy is required when using the following policy templates:

- General data leaks
- Data leaks by priority users

See the Create, test, and tune a DLP policy article for step-by-step guidance to configure DLP policies for your organization. After you've configured a DLP policy, return to these configuration steps.

Configure priority user groups

Insider risk management includes support for assigning priority user groups to policies to help identity unique risk activities for user with critical positions, high levels of data and network access, or a past history of risk behavior. Creating a priority user group and assigning users to the group help scope policies to the unique circumstances presented by these users.

A priority user group is required when using the following policy templates:

- Security policy violations by priority users
- Data leaks by priority users

See the Getting started with insider risk management settings article for step-by-step guidance to create a priority user group. After you've configured a priority user group, return to these configuration steps.

Configure Physical badging connector (optional)

Insider risk management supports importing user and log data imported from physical control and access platforms. The Physical badging connector allows you to pull in access data from JSON files, including user IDs, access point IDs, access time and dates, and access status. This data helps drive alert indicators in insider risk management policies and is an important part of configuring full risk management coverage in your organization. If you configure more than one Physical badging connector for your organization, insider risk management automatically pulls indicators from all Physical badging connectors. Information from the Physical badging connector supplements other insider risk signals when using all insider risk policy templates.

> **IMPORTANT**
>
> For insider risk management policies to use and correlate signal data related to departing and terminated users with event data from your physical control and access platforms, you must also configure the Microsoft 365 HR connector. If you enable the Physical badging connector without enabling the Microsoft 365 HR connector, insider risk management policies will only process events for unauthorized physical access for users in your organization.

See the Set up a connector to import physical badging data article for step-by-step guidance to configure the Physical badging connector for your organization. After you've configured the connector, return to these configuration steps.

Step 4: Configure insider risk settings

Insider risk settings apply to all insider risk management policies, regardless of the template you chose when creating a policy. Settings are configured using the **Insider risk settings** control located at the top of all insider risk management tabs. These settings control privacy, indicators, monitoring windows, and intelligent detections.

Before configuring a policy, define the following insider risk settings:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select **Insider risk settings** from the top-right corner of any page.
2. On the **Privacy** page, select a privacy setting for displaying usernames for policy alerts.
3. On the **Indicators** page, select the alert indicators you want to apply to all insider risk policies.

   > **IMPORTANT**
   > In order to receive alerts for risky activity defined in your policies, you must select one or more indicators.

4. On the **Policy timeframes** page, select the policy timeframes to go into effect for a user when they trigger a match for an insider risk policy.
5. On the **Intelligent detections** page, configure the following settings for insider risk policies:
   - Anomaly detections
   - Alert volume level
   - Microsoft Defender for Endpoint alert status
   - Domain settings
6. On the **Export alerts** page, enable export of insider risk alert information using the Office 365 Management APIs if needed.
7. On the **Priority user groups** page, create a priority user group and add users if not created in **Step 3**.
8. On the **Power Automate flows** page, configure a flow from insider risk flow templates or create a new flow. See the Getting started with insider risk management settings article for step-by-step guidance.
9. On the **Priority assets page**, configure priority assets to use data from your physical control and access platform imported by the Physical badging connector. See the Getting started with insider risk management settings article for step-by-step guidance.
10. On the **Microsoft Teams** page, enable Microsoft Teams integration with insider risk management to automatically create a team for case or user collaboration. See the Getting started with insider risk management settings article for step-by-step guidance.
11. Select **Save** to enable these settings for your insider risk policies.

Step 5: Create an insider risk management policy

Insider risk management policies include assigned users and define which types of risk indicators are configured for alerts. Before activities can trigger alerts, a policy must be configured.

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Policies** tab.
2. Select **Create policy** to open the policy wizard.
3. On the **New insider risk policy** page, complete the following fields:
   - **Name (required)**: Enter a friendly name for the policy.

- **Description (optional)**: Enter a description for the policy.
- **Choose policy template (required)**: Select one of the policy templates to define the types of risk indicators are monitored by the policy.

> **IMPORTANT**
> Most policy templates have prerequisites that must be configured for the policy to generate relevant alerts. If you haven't configured the applicable policy prerequisites, see **Step 3** above.

4. Select **Next** to continue.
5. On the **Users** page, select **Add user or group** or **Choose Priority user groups** to define which users or priority user groups are included in the policy, depending on the policy template you've selected. Select **All users and mail-enabled groups** checkbox if applicable (if you haven't selected a priority user-based template). Select **Next** to continue.
6. On the **Specify what content to prioritize (optional)** page, you can assign the sources to prioritize for increased risk scores. However, some activities won't generate an alert at all unless the related content contains built-in or custom sensitive info types or was specified as a priority on this page:
   - **SharePoint sites**: Select **Add SharePoint site** and select the SharePoint organizations you want to prioritize. For example, *"group1@contoso.sharepoint.com/sites/group1"*.
   - **Sensitive info type**: Select **Add sensitive info type** and select the sensitivity types you want to prioritize. For example, *"U.S. Bank Account Number"* and *"Credit Card Number"*.
   - **Sensitivity labels**: Select **Add sensitivity label** and select the labels you want to prioritize. For example, *"Confidential"* and *"Secret"*.
7. Select **Next** to continue.
8. On the **Select policy indicators** page, you'll see the indicators that you've defined as available on the **Insider risk settings** > **Indicators** page. If you selected a *Data leaks* template at the beginning of the wizard, you must select a DLP policy from the **DLP policy** dropdown list to enable triggering indicators for the policy. Select the indicators you want to apply to the policy. If you prefer not to use the default policy threshold settings for these indicators, disable the **Use default thresholds recommended by Microsoft** and enter the threshold values for each selected indicator. If you've selected at least one *Office* or *Device* indicator, select the **Risk score boosters** as appropriate. Risk score boosters are only applicable for selected indicators.

   > **IMPORTANT**
   > If indicators on this page can't be selected, you'll need to select the indicators you want to enable for all policies on the **Insider risk management** > **Settings** > **Policy indicators** page.

9. Select **Next** to continue.
10. On the **Policy timeframes** page, you'll see the activation window conditions for the policy that on the **Insider risk settings** > **Policy timeframes** page.
11. Select **Next** to continue.
12. On the **Review** page, review the settings you've chosen for the policy. Select **Edit** to change any of the policy values or select **Submit** to create and activate the policy.

Next steps

After you've completed these steps to create your first insider risk management policy, you'll start to receive

alerts from activity indicators after about 24 hours. Configure additional policies as needed using the guidance in Step 4 of this article or the steps in Create a new insider risk policy.

To learn more about investigating insider risk alerts and the **Alerts dashboard**, see Insider risk management alerts.

Insider risk management policies

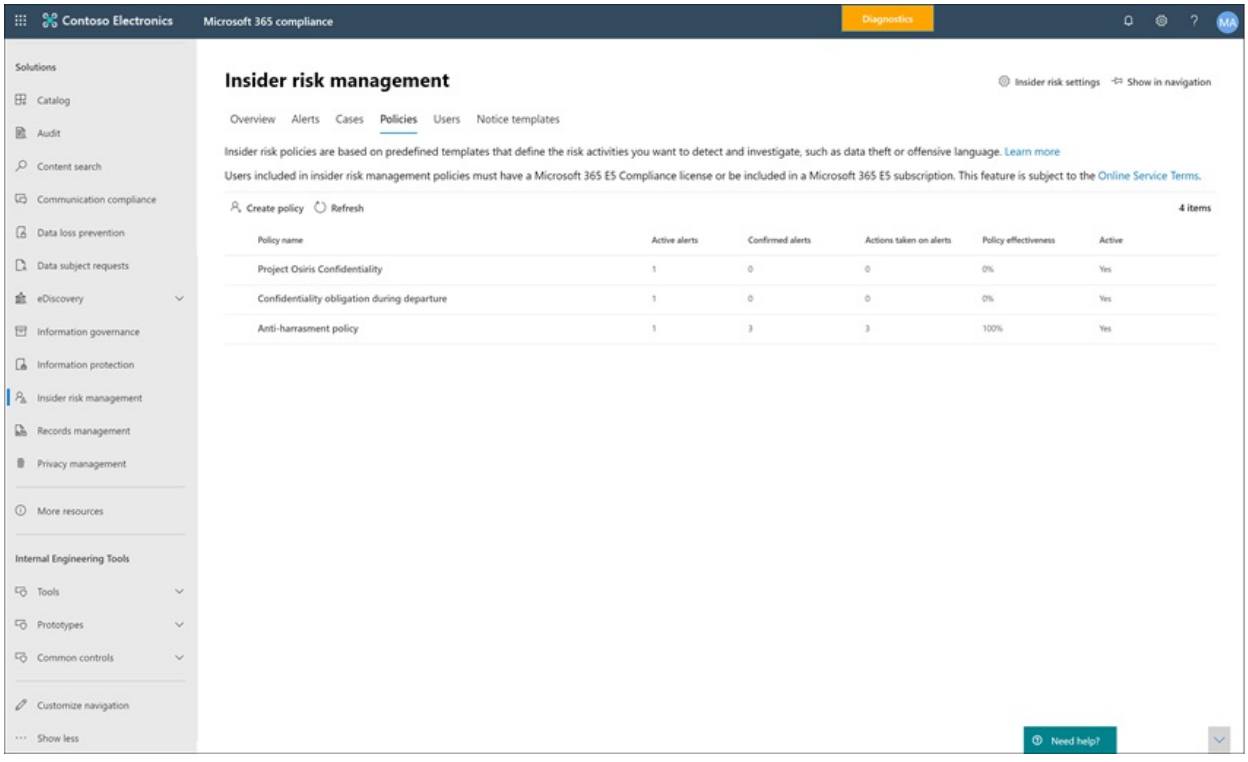
2/18/2021 • 19 minutes to read • Edit Online

Insider risk management policies determine which users are in-scope and which types of risk indicators are configured for alerts. You can quickly create a policy that applies to all users in your organization or define individual users or groups for management in a policy. Policies support content priorities to focus policy conditions on multiple or specific Microsoft Teams, SharePoint sites, data sensitivity types, and data labels. Using templates, you can select specific risk indicators and customize event thresholds for policy indicators, effectively customizing risk scores and level and frequency of alerts. Additionally, risk score boosters and anomaly detections help identify user activity that is of higher importance or more unusual. Policies windows allow you to define the time frame to apply the policy to alert activities and are used to determine the duration of the policy once activated.

Policy dashboard

The **Policy dashboard** allows you to quickly see the policies in your organization and the current status of alerts associated with each policy.

- **Policy name**: The name assigned to the policy in the policy wizard.
- **Active alerts**: The number of active alerts for each policy.
- **Confirmed alerts**: The total number of alerts the resulted in cases from the policy in the last 365 days.
- **Actions taken on alerts**: The total number of alerts that were confirmed or dismissed for the last 365 days.
- **Policy effectiveness**: The percentage determined by total confirmed alerts divided by total actions taken on alerts (which is the sum of alerts that were confirmed or dismissed over the past year).
- **Active**: The status of the case, either *Yes* or *No*.



Policy templates

Insider risk management templates are pre-defined policy conditions that define the types of risk indicators and

risk scoring model used by the policy. Each policy must have a template assigned in the policy creation wizard before the policy is created. Insider risk management supports up to five policies for each policy template. When you create a new insider risk policy with the policy wizard, you'll choose from one of the following policy templates:

Data theft by departing users

When users leave your organization, there are specific risk indicators typically associated with data theft by departing users. This policy template uses indicators for risk scoring and focuses detection and alerts to this risk area. Data theft for departing users may include downloading files from SharePoint Online, printing files, and copying data to personal cloud messaging and storage services near their employment resignation and end dates. This template starts scoring for risk indicators relating to these activities and how they correlate with user employment status.

> **IMPORTANT**
> When using this template, you must configure a Microsoft 365 HR connector to periodically import resignation and termination date information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.

General data leaks

Protecting data and preventing data leaks is a constant challenge for most organizations, particularly with the rapid grow of new data created by users, devices, and services. Users are empowered to create, store, and share information across services and devices that make managing data leaks increasingly more complex and difficult. Data leaks can include accidental oversharing of information outside your organization or data theft with malicious intent. In conjunction with an assigned Data Loss Prevention (DLP) policy, this template starts scoring real-time detections of suspicious SharePoint Online data downloads, file and folder sharing, printing files, and copying data to personal cloud messaging and storage services.

When using a **Data leaks** template, you must assign a DLP policy to trigger indicators in the insider risk policy for high severity alerts in your organization. Whenever a high severity alert is generated by a DLP policy rule is added to the Office 365 audit log, insider risk policies created with this template automatically examine the high severity DLP alert. If the alert contains an in-scope user defined in the insider risk policy, the alert is processed by the insider risk policy as a new alert and assigned an insider risk severity and risk score. This policy allows you to evaluate this alert in context with other activities included in the case.

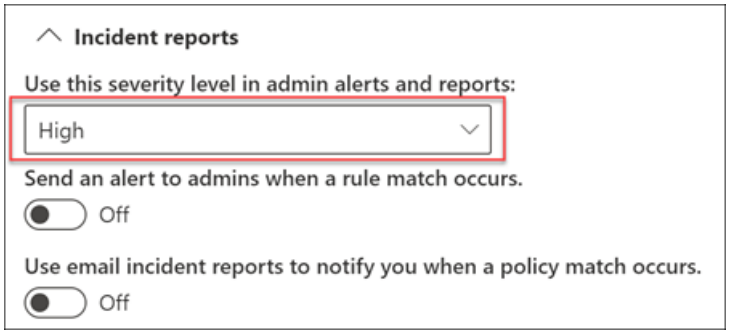
Data leaks policy guidelines

When creating or modifying DLP policies for use with insider risk management policies, consider the following guidelines:

- Prioritize data exfiltration events and be selective when assigning **Incident reports** settings to *High* when configuring rules in your DLP policies. For example, emailing sensitive documents to a known competitor should be a *High* alert level exfiltration event. Over-assigning the *High* level in the **Incident reports** settings in other DLP policy rules can increase the noise in the insider risk management alert workflow and make it more difficult for your data investigators and analysts to properly evaluate these alerts. For example, assigning *High* alert levels to access denial activities in DLP policies makes it more challenging to evaluate truly risky user behavior and activities.
- Make sure you understand and properly configure the in-scope users in both the DLP and insider risk management policies. Only users defined as in-scope for insider risk management policies using the **Data leaks** template will have high severity DLP policy alerts processed. Additionally, only users defined as in-scope in a rule for a high severity DLP alert will be examined by the insider risk management policy for consideration. It is important that you don't unknowingly configure in-scope users in both your DLP and insider risk policies in a conflicting manner.

For example, if your DLP policy rules are scoped to only users on the Sales Team and the insider risk policy created from the **Data leaks** template has defined all users as in-scope, the insider risk policy will only actually process high severity DLP alerts for the users on the Sales Team. The insider risk policy won't receive any high priority DLP alerts for users to process that aren't defined in the DLP rules in this example. Conversely, if your insider risk management policy created from **Data leaks** templates is scoped to only users on the Sales Team and the assigned DLP policy is scoped to all users, the insider risk policy will only process high severity DLP alerts for members of the Sales Team. The insider risk management policy will ignore high severity DLP alerts for all users not on the Sales Team.

- Make sure the **Incident reports** rule setting in the DLP policy used for this insider risk management template is configured for *High* severity level alerts. The *High* severity level is the triggering events and insider risk management alerts won't be generated from rules in DLP policies with the **Incident reports** field set at *Low* or *Medium*.



> **NOTE**
> When creating a new DLP policy using the built-in templates, you'll need to select the **Create or customize advanced DLP rules** option to configure the **Incident reports** setting for the *High* severity level.

Each insider risk management policy created from the **Data leaks** template can only have one DLP policy assigned. Consider creating a dedicated DLP policy that combines the different activities you want to detect and act as triggering events for insider risk policies that use the **Data leaks** template.

See the Create, test, and tune a DLP policy article for step-by-step guidance to configure DLP policies for your organization.

Data leaks by priority users (preview)

Protecting data and preventing data leaks for users in your organization may depend on their position, level of access to sensitive information, or risk history. Data leaks can include accidental oversharing of highly sensitive information outside your organization or data theft with malicious intent. In conjunction with an assigned Data Loss Prevention (DLP) policy, this template starts scoring real-time detections of suspicious activity and result in an increased likelihood of insider risk alerts and alerts with higher severity levels. Priority users are defined in priority user groups configured in the insider risk management settings area.

As with the **General data leaks template**, you must assign a DLP policy to trigger indicators in the insider risk policy for high severity alerts in your organization. Follow the Data leaks policy guidelines above when creating a policy using this template. Additionally, you will need to assign priority user groups created in **Insider risk management** > **Settings** > **Priority user groups** to the policy.

Data leaks by disgruntled users (preview)

When users experience employment stressors, they may become disgruntled which may increase the chances of insider risk activity. This template starts scoring user activity when an indicator associated with disgruntlement is identified. Examples include performance improvement notifications, poor performance reviews, or changes to job level status. Data leaks for disgruntled users may include downloading files from SharePoint Online and copying data to personal cloud messaging and storage services near employment stressor events.

When using this template, you must also configure a Microsoft 365 HR connector to periodically import performance improvement notifications, poor performance review status, or job level change information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.

General security policy violations (preview)

In many organizations, users have permissions to install software on their devices or to modify device settings to help with their tasks. Either inadvertently or with malicious intent, users may install malware or disable important security features that help protect information on their device or on your network resources. This policy template uses security alerts from Microsoft Defender for Endpoint to start scoring these activities and focus detection and alerts to this risk area. Use this template to provide insights for security policy violations in scenarios when users may have a history of security policy violations that may be an indicator of insider risk.

You'll need to have Microsoft Defender for Endpoint configured in your organization and enable Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Defender for Endpoint.

Security policy violations by departing users (preview)

Departing users, whether leaving on positive or negative terms, may be higher risks for security policy violations. To help protect against inadvertent or malicious security violations for departing users, this policy template uses Defender for Endpoint alerts to provide insights into security-related activities. These activities include the user installing malware or other potentially harmful applications and disabling security features on their devices. Policy indicators are activated after users have a resignation or termination date imported from the Microsoft 365 HR Connector as a triggering event.

When using this template, you must configure a Microsoft 365 HR connector to periodically import resignation and termination date information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.

You'll need to have Microsoft Defender for Endpoint configured in your organization and enable Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Defender for Endpoint.

Security policy violations by priority users (preview)

Protecting against security violations for users in your organization may depend on their position, level of access to sensitive information, or risk history. Because security violations by priority users may have an outsized impact on your organization's critical areas, this policy template starts scoring on these indicators and uses Microsoft Defender for Endpoint alerts to provide insights into security-related activities for these users. These may include the priority users installing malware or other potentially harmful applications and disabling security features on their devices. Priority users are defined in priority user groups configured in the insider risk management settings area.

You'll need to have Microsoft Defender for Endpoint configured in your organization and enable Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Defender for Endpoint. Additionally, you will need to assign priority user groups created in **Insider risk management** > **Settings** > **Priority user groups** to the policy.

Security policy violations by disgruntled users (preview)

Users that experience employment stressors may be at a higher risk for inadvertent or malicious security policy violations. These stressors may include the user being placed on a performance improvement plan, poor performance review status, or being demoted from their current position. This policy template starts risk scoring based these indicators and activities associated with these events for these users.

When using this template, you must also configure a Microsoft 365 HR connector to periodically import performance improvement notifications, poor performance review status, or job level change information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector for your organization.

You'll also need to have Microsoft Defender for Endpoint configured in your organization and enable Defender for Endpoint for insider risk management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for insider risk management integration, see Configure advanced features in Defender for Endpoint.

Policy template prerequisites and triggering events

Depending on the template you choose for an insider risk management policy, the triggering events and policy prerequisites vary. Triggering events are prerequisites that determine if a user is active for an insider risk management policy. If a user is added to an insider risk management policy but does not have a triggering event, the user activity is not evaluated by the policy unless they are manually added in the Users dashboard. Policy prerequisites are required items so that the policy receives the signals or activities necessary to evaluate risk.

The following table lists the triggering events and prerequisites for policies created from each insider risk management policy template:

POLICY TEMPLATE	TRIGGERING EVENTS FOR POLICIES	PREREQUISITES
Data theft by departing users	Resignation or termination date indicator from HR connector	Microsoft 365 HR connector configured for termination and resignation date indicators
General data leaks	Data leak policy activity that creates a High severity alert	DLP policy configured for High severity alerts
Data leaks by priority users	Data leak policy activity that creates a High severity alert	DLP policy configured for High severity alerts Priority user groups configured in insider risk settings
Data leaks by disgruntled users	Performance improvement, poor performance, or job level change indicators from HR connector	Microsoft 365 HR connector configured for disgruntlement indicators
General security policy violations	Defensive evasion of security controls or unwanted software detected by Microsoft Defender for Endpoint	Active Microsoft Defender for Endpoint subscription Microsoft Defender for Endpoint integration with Microsoft 365 compliance center configured
Security policy violations by departing users	Resignation or termination date indicators from HR connector	Microsoft 365 HR connector configured for termination and resignation date indicators Active Microsoft Defender for Endpoint subscription Microsoft Defender for Endpoint integration with Microsoft 365 compliance center configured

POLICY TEMPLATE	TRIGGERING EVENTS FOR POLICIES	PREREQUISITES
Security policy violations by priority users	Defensive evasion of security controls or unwanted software detected by Microsoft Defender for Endpoint	Active Microsoft Defender for Endpoint subscription Microsoft Defender for Endpoint integration with Microsoft 365 compliance center configured Priority user groups configured in insider risk settings
Security policy violations by disgruntled user	Performance improvement, poor performance, or job level change indicators from HR connector	Microsoft 365 HR connector configured for disgruntlement indicators Active Microsoft Defender for Endpoint subscription Microsoft Defender for Endpoint integration with Microsoft 365 compliance center configured

Prioritize content in policies

Insider risk management policies support specifying a higher priority for content depending where it is stored or how it is classified. Specifying content as a priority increases the risk score for any associated activity, which in turn increases the chance of generating a high severity alert. However, some activities won't generate an alert at all unless the related content contains built-in or custom sensitive info types or was specified as a priority in the policy.

For example, your organization has a dedicated SharePoint site for a highly confidential project. Data leaks for information in this SharePoint site could compromise the project and would have a significant impact on its success. By prioritizing this SharePoint site in a Data leaks policy, risk scores for qualifying activities are automatically increased. This prioritization increases the likelihood that these activities generate an insider risk alert and raises the severity level for the alert.

When you create an insider risk management policy in the policy wizard, you can choose from the following priorities:

- **SharePoint sites**: Any activity associated with all file types in defined SharePoint sites is assigned a higher risk score.
- **Sensitive information types**: Any activity associated with content that contains sensitive information types are assigned a higher risk score.
- **Sensitivity labels**: Any activity associated with content that has specific sensitivity labels applied are assigned a higher risk score.

Create a new policy

To create a new insider risk management policy, you'll use the policy wizard in **Insider risk management** solution in the Microsoft 365 compliance center.

Complete the following steps to create a new policy:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Policies** tab.
2. Select **Create policy** to open the policy wizard

3. On the **New insider risk policy** page, complete the following fields:

   - **Name (required)**: Enter a friendly name for the policy.
   - **Description (optional)**: Enter a description for the policy.
   - **Choose policy template (required)**: Select one of the policy templates to define the types of risk indicators are monitored by the policy.

   > **IMPORTANT**
   > Most policy templates have prerequisites that must be configured for the policy to generate relevant alerts. If you haven't configured the applicable policy prerequisites, see Get started with insider risk management.

4. Select **Next** to continue.

5. On the **Users** page, select **Add user or group** or **Choose Priority user groups** to define which users or priority user groups are included in the policy, depending on the policy template you've selected. Select **All users and mail-enabled groups** checkbox if applicable (if you haven't selected a priority user-based template). Select **Next** to continue.

6. On the **Specify what content to prioritize (optional)** page, you can assign the sources to prioritize for increased risk scores. However, some activities won't generate an alert at all unless the related content contains built-in or custom sensitive info types or was specified as a priority on this page:

   - **SharePoint sites**: Select **Add SharePoint site** and select the SharePoint organizations you want to prioritize. For example, *"group1@contoso.sharepoint.com/sites/group1"*.
   - **Sensitive info type**: Select **Add sensitive info type** and select the sensitivity types you want to prioritize. For example, *"U.S. Bank Account Number"* and *"Credit Card Number"*.
   - **Sensitivity labels**: Select **Add sensitivity label** and select the labels you want to prioritize. For example, *"Confidential"* and *"Secret"*.

7. Select **Next** to continue.

8. On the **Select policy indicators** page, you'll see the indicators that you've defined as available on the **Insider risk settings** > **Indicators** page. If you selected a *Data leaks* template at the beginning of the wizard, you must select a DLP policy from the **DLP policy** dropdown list to enable triggering indicators for the policy. Select the indicators you want to apply to the policy. If you prefer not to use the default policy threshold settings for these indicators, disable the **Use default thresholds recommended by Microsoft** and enter the threshold values for each selected indicator. If you've selected at least one *Office* or *Device* indicator, select the **Risk score boosters** as appropriate. Risk score boosters are only applicable for selected indicators.

   > **IMPORTANT**
   > If indicators on this page can't be selected, you'll need to select the indicators you want to enable for all policies on the **Insider risk management** > **Settings** > **Policy indicators** page.

9. Select **Next** to continue.

10. On the **Policy timeframes** page, you'll see the activation window conditions for the policy that on the **Insider risk settings** > **Policy timeframes** page.

11. Select **Next** to continue.

12. On the **Review** page, review the settings you've chosen for the policy. Select **Edit** to change any of the policy values or select **Submit** to create and activate the policy.

Update a policy

To update an existing insider risk management policy, you'll use the policy wizard in **Insider risk management** solution in the Microsoft 365 compliance center.

Complete the following steps to manage an existing policy:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Policies** tab.
2. On the policy dashboard, select the policy you want to manage.
3. On the policy details page, select **Edit policy**
4. In the policy wizard, you cannot edit the following fields:
   - **Name**: The friendly name for the policy
   - **Choose policy template**: The template used to define the types of risk indicators monitored by the policy.
5. Enter a new description for the policy in the **Description** field.
6. Select **Next** to continue.
7. On the **Users** page, select **Add user or group** or **Choose Priority user groups** to define which users or priority user groups are included in the policy, depending on the policy template you've selected. Select **All users and mail-enabled groups** checkbox if applicable (if you haven't selected a priority user-based template). Select **Next** to continue.
8. On the **Specify what content to prioritize (optional)** page, you can assign the sources to prioritize for increased risk scores. However, some activities won't generate an alert at all unless the related content contains built-in or custom sensitive info types or was specified as a priority on this page:
   - **SharePoint sites**: Select **Add SharePoint site** and select the SharePoint organizations you want to prioritize. For example, *"group1@contoso.sharepoint.com/sites/group1"*.
   - **Sensitive info type**: Select **Add sensitive info type** and select the sensitivity types you want to prioritize. For example, *"U.S. Bank Account Number"* and *"Credit Card Number"*.
   - **Sensitivity labels**: Select **Add sensitivity label** and select the labels you want to prioritize. For example, *"Confidential"* and *"Secret"*.
9. Select **Next** to continue.
10. On the **Select policy indicators** page, you'll see the indicators that you've defined as available on the **Insider risk settings** > **Indicators** page. If you selected a *Data leaks* template at the beginning of the wizard, you must select a DLP policy from the **DLP policy** dropdown list to enable triggering indicators for the policy. Select the indicators you want to apply to the policy. If you prefer not to use the default policy threshold settings for these indicators, disable the **Use default thresholds recommended by Microsoft** and enter the threshold values for each selected indicator. If you've selected at least one *Office* or *Device* indicator, select the **Risk score boosters** as appropriate. Risk score boosters are only applicable for selected indicators.

    > **IMPORTANT**
    > If indicators on this page can't be selected, you'll need to select the indicators you want to enable for all policies on the **Insider risk management** > **Settings** > **Policy indicators** page.

11. Select **Next** to continue.
12. On the **Policy timeframes** page, you'll see the activation window conditions for the policy that on the **Insider risk settings** > **Policy timeframes** page.

13. Select **Next** to continue.
14. On the **Review** page, review the settings you've updated for the policy. Select **Edit** to change any of the policy values or select **Submit** to update and activate the policy.

Delete a policy

> **NOTE**
> Deleting a policy does not delete active or archived alerts generated from the policy.

To delete an existing insider risk management policy, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Policies** tab.
2. On the policy dashboard, select the policy you want to delete.
3. Select **Delete** on the dashboard toolbar.
4. On the **Delete** dialog, Select **Yes** to delete the policy, or select **Cancel** to close the dialog.

Insider risk management alerts

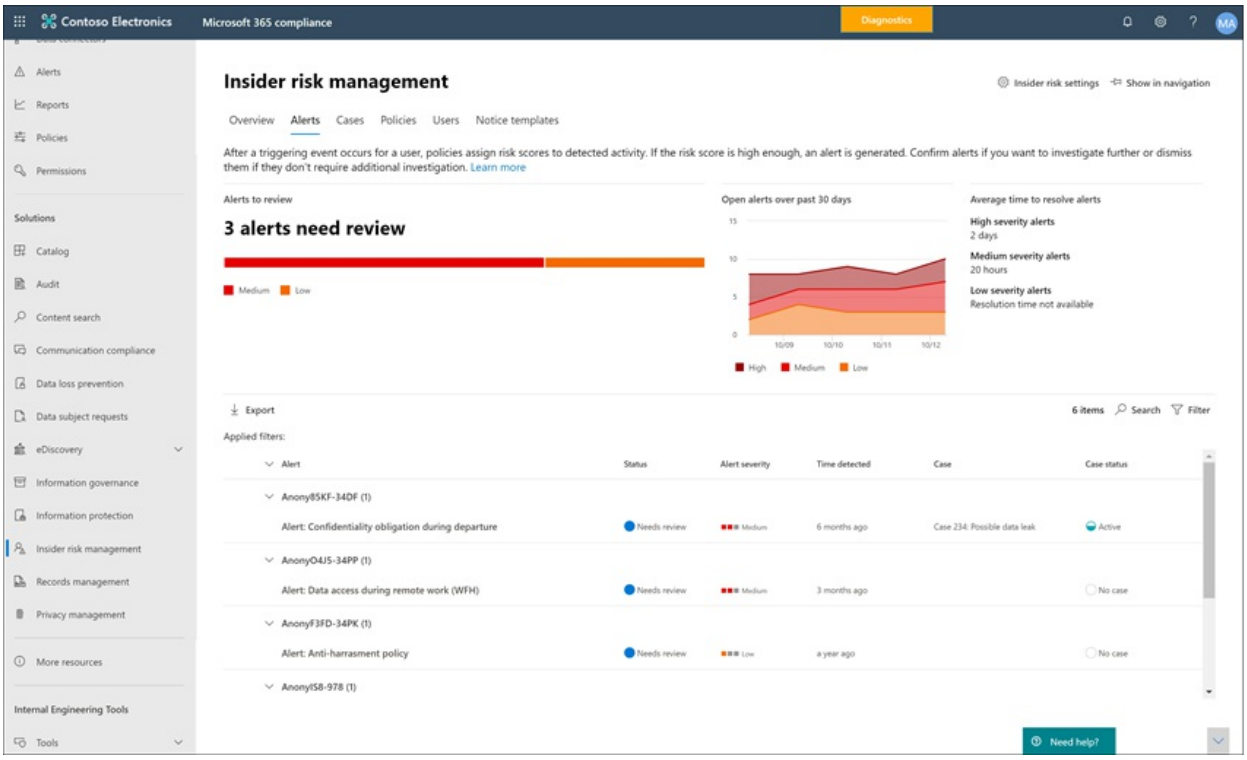
11/2/2020 • 7 minutes to read • Edit Online

Insider risk management alerts are automatically generated by risk indicators defined in insider risk management policies. These alerts give compliance analysts and investigators an all-up view of the current risk status and allow your organization to triage and take actions for discovered risks. By default, policies generate a certain amount of low, medium, and high severity alerts, but you can increase or decrease the alert volume to suit your needs. Additionally, you can configure the alert threshold for policy indicators when creating a new policy with the policy wizard.

Alert dashboard

The insider risk **Alert dashboard** allows you to view and act on alerts generated by insider risk policies. Each report widget displays information for last 30 days.

- **Alerts to review**: The total number of alerts needing review and triage are listed, including a breakdown by alert severity.
- **Open alerts over past 30 days**: The total number of alerts created by policy matches over the last 30 days, sorted by high, medium, and low alert severity levels.
- **Average time to resolve alerts**: A summary of useful alert statistics:
  - Average time to resolve high severity alerts, listed in hours, days, or months.
  - Average time to resolve medium severity alerts, listed in hours, days, or months.
  - Average time to resolve low severity alerts, listed in hours, days, or months.



> **NOTE**
>
> Insider risk management uses built-in alert throttling to help protect and optimize your risk investigation and review experience. This throttling guards against issues that might result in an overload of policy alerts, such as misconfigured data connectors or DLP policies. As a result, there might be a delay in displaying new alerts for a user.

Alert status and severity

You can triage alerts into one of the following statuses:

- **Confirmed**: An alert confirmed and assigned to a new or existing case.
- **Dismissed**: An alert dismissed as benign in the triage process.
- **Needs review**: A new alert where triage actions have not yet been taken.
- **Resolved**: An alert that is part of a closed and resolved case.

Alert risk scores are automatically calculated from several risk activity indicators. These indicators include the type of risk activity, the number and frequency of the activity occurrence, the history of user risk activity, and the addition of activity risks that may boost the seriousness of the activity. The alert risk score drives the programmatic assignment of a risk severity level for each alert and cannot be customized. If alerts remain untriaged and risk activities continue to accrue to the alert, the risk severity level can increase. Risk analysts and investigators can use the alert risk severity to help triage alerts in accordance with your organization's risk policies and standards.

Alert risk severity levels are:

- **High severity**: The activities and indicators for the alert pose significant risk. The associated risk activities are serious, repetitive, and corelate strongly to other significant risk factors.
- **Medium severity**: The activities and indicators for the alert pose a moderate risk. The associated risk activities are moderate, frequent, and have some correlation to other risk factors.
- **Low severity**: The activities and indicators for the alert pose a minor risk. The associated risk activities are minor, more infrequent, and do not corelate to other significant risk factors.

Filter alerts on the Alert dashboard

Depending on the number and type of active insider risk management policies in your organization, reviewing a large queue of alerts can be challenging. Using alert filters can help analysts and investigators sort alerts by several attributes. To filter alerts on the **Alerts dashboard**, select the **Filter** control. You can filter alerts by one or more attributes:

- **Status**: Select one or more status values to filter the alert list. The options are *Confirmed*, *Dismissed*, *Needs review*, and *Resolved*.
- **Severity**: Select one or more alert risk severity levels to filter the alert list. The options are *High*, *Medium*, and *Low*.
- **Time detected**: Select the start and end dates for when the alert was created.
- **Policy**: Select one or more policies to filter the alerts generated by the selected policies.

Search alerts on the Alert dashboard

To search the alert name for a specific word, select the **Search** control and type the word to search. The search results display any policy alert containing the word defined in the search.

Triage alerts

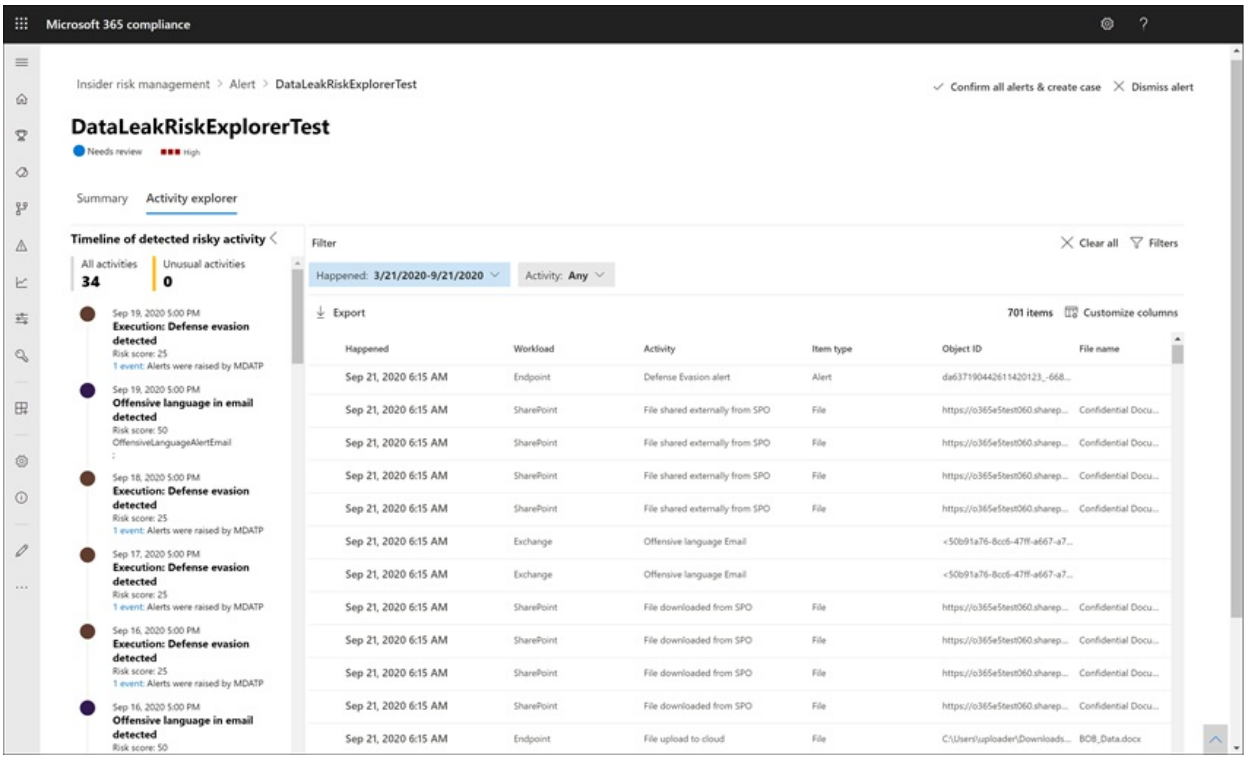
To triage an insider risk alert, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Alerts** tab.
2. On the **Alerts dashboard**, select the alert you want to triage.
3. On the **Alerts detail pane**, you can review the following tabs and triage the alert:
   - **Summary**: This tab contains general information about the alert and allows you to confirm the alert and create a new case or allows you to dismiss the alert. It includes the current status for the alert and the alert risk severity level, listed as *High*, *Medium*, or *Low*. The severity level may increase or decrease over time if the alert is not triaged.
     - **What happened**: Displays the top three risk activities and policy matches during the activity evaluation period, including the type of violation associated with the activity.
     - **User details**: Displays general information about the user assigned to the alert. If anonymization is enabled, the username, email address, alias, and organization fields are anonymized.
     - **Alert details**: Includes the length of time since the alert was generated, the policies that generated the alert are listed, and the case generated from the alert is listed. For new alerts, the **Case** field displays None.
     - **Content detected**: Includes content associated with the risk activities for the alert and summarizes activity events by key areas. Selecting an activity link opens the Activity explorer and displays additional details about the activity.
   - **User activity**: This tab displays the activity history for the user associated with the alert. This history includes other alerts and activities related to risk indicators defined in the template assigned to the policy for this alert. This history allows risk analysts and investigators to factor in any past risky behavior for the employee as part of the triage process.
   - **Actions**: The following actions are available for each alert:
     - **Open expanded view**: Opens the **Activity explorer** dashboard.
     - **Confirm and create case**: Use this action to confirm and create a new case for all the alerts associated with a user. This action automatically changes the alert status to *Confirmed*.
     - **Dismiss alert**: Use this action to dismiss the alert. This action changes the alert status to *Resolved*.

Activity explorer (preview)

> **NOTE**
> Activity explorer is available in the alert management area for users with triggering events after this feature is available in your organization.

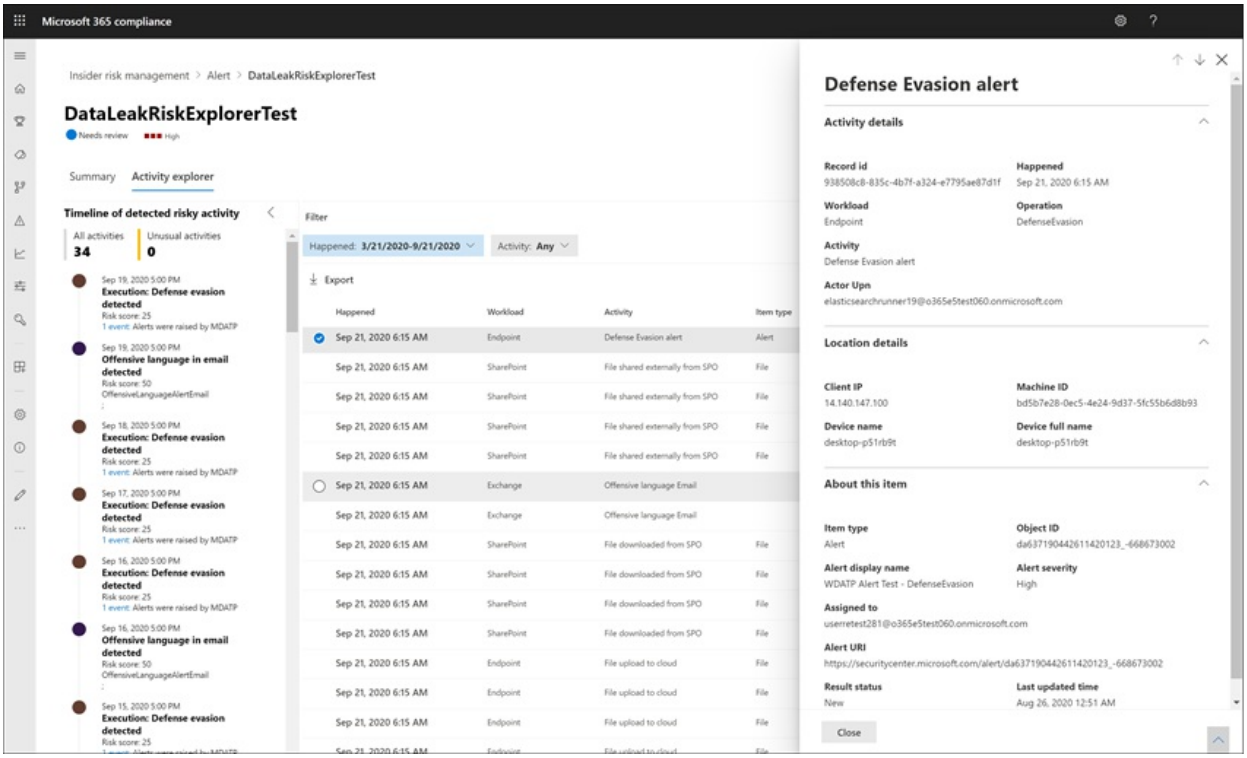
The Activity explorer provides risk investigators and analysts with a comprehensive analytic tool that provides detailed information about alerts. With the Activity explorer, reviewers can quickly review a timeline of detected risky activity and identify and filter all risk activities associated with alerts. To filter alerts on the Activity explorer, select the Filter control. You can filter alerts by one or more attributes listed in the details pane for the alert. Activity explorer also supports customizable columns to help investigators and analysts focus the dashboard on the information most important to them.



To use the **Activity explorer**, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Alerts** tab.
2. On the **Alerts dashboard**, select the alert you want to triage.
3. On the **Alerts detail pane**, select **Open expanded view**.
4. On the page for the selected alert, select the **Activity explorer** tab.

When reviewing activities in the Activity explorer, investigators and analysts can select a specific activity and open the activity details pane. The pane displays detailed information about the activity that investigators and analysts can use during the alert triage process. The detailed information may provide context for the alert and assist with identifying the full scope of the risk activity that triggered the alert.



Create a case for an alert

As alert is reviewed and triaged, you can create a new case to further investigate the risk activity. To create a case for an alert, follow these steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Alerts** tab.
2. On the **Alerts dashboard**, select the alert you want to confirm and create a new case for.
3. On the **Alerts details pane**, select **Actions** > **Confirm alerts & create case**.
4. On the **Confirm alert and create insider risk case** dialog, enter a name for the case, select users to add as contributors, and add comments as applicable. Comments are automatically added to the case as a case note.
5. Select **Create case** to create a new case or select **Cancel** to close the dialog without creating a case.

After the case is created, investigators and analysts can manage and act on the case. See the Insider risk management case article for more details.

Insider risk management cases

2/18/2021 • 16 minutes to read • Edit Online

Cases are the heart of insider risk management and allow you to deeply investigate and act on issues generated by risk indicators defined in your policies. Cases are manually created from alerts in situations where further action is needed to address a compliance-related issue for a user. Each case is scoped to a single user and multiple alerts for the user can be added to an existing case or to a new case.

After investigating the details of a case, you can take action by:

- sending the user a notice
- resolving the case as benign
- sharing the case with your ServiceNow instance or with an email recipient
- escalating the case for an Advanced eDiscovery investigation

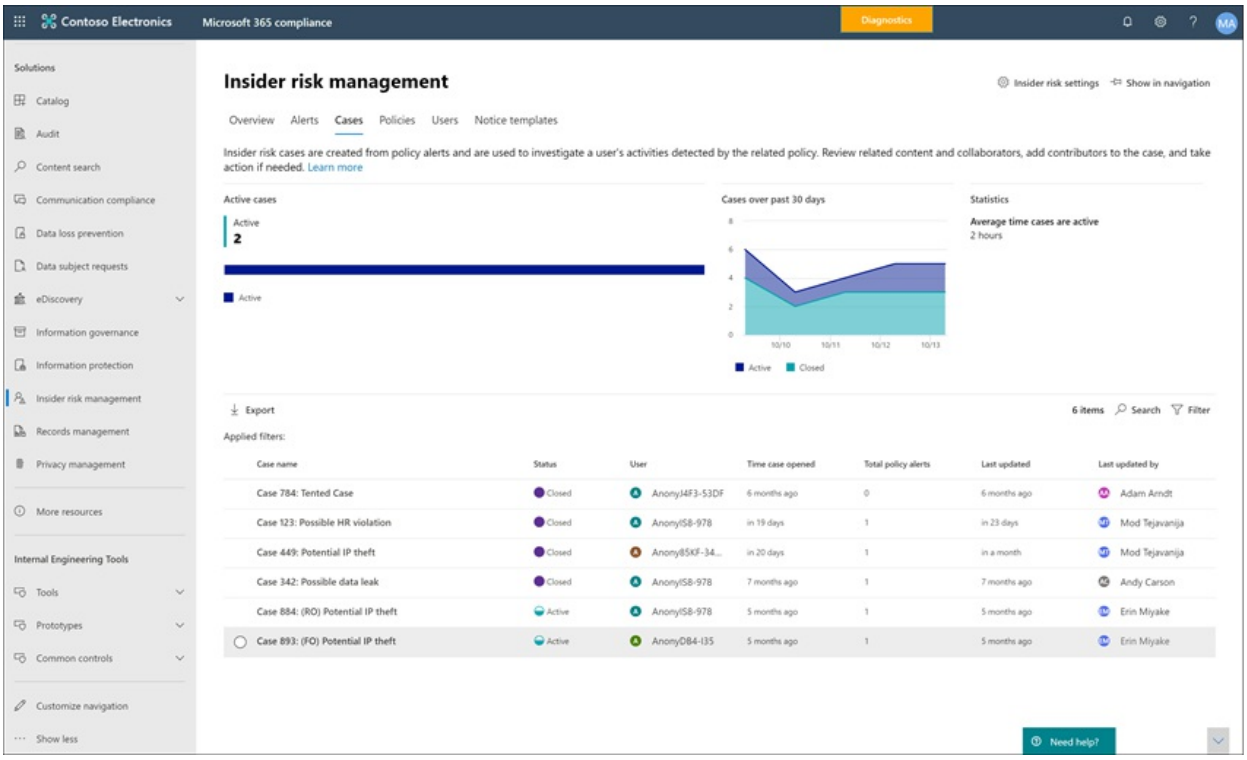
Cases dashboard

The insider risk management **Cases dashboard** allows you to view and act on cases. Each report widget on the dashboard displays information for last 30 days.

- **Active cases**: The total number of active cases under investigation.
- **Cases over past 30 days**: The total number of cases created, sorted by *Active* and *Closed* status.
- **Statistics**: Average time of active cases, listed in hours, days, or months.

The case queue lists all active and closed cases for your organization, in addition to the current status of the following case attributes:

- **Case name**: The name of the case, defined when an alert is confirmed and the case is created.
- **Status**: The status of the case, either *Active* or *Closed*.
- **User**: The user for the case. If anonymization for usernames is enabled, anonymized information is displayed.
- **Time case opened**: The time that has passed since the case was opened.
- **Total policy alerts**: The number of policy matches included in the case. This number may increase if new alerts are added to the case.
- **Last updated**: The time that has passed since there has been an added case note or change in the case state.
- **Last updated by**: The name of the insider risk management analyst or investigator that last updated the case.



Use the **Search** control to search case names for specific text and use the case filter to sort cases by the following attributes:

- Status
- Time case opened, start date, and end date
- Last updated, start date, and end date

Filter cases

Depending on the number and type of active insider risk management policies in your organization, reviewing a large queue of cases can be challenging. Using case filters can help analysts and investigators sort cases by several attributes. To filter alerts on the **Cases dashboard**, select the **Filter** control. You can filter cases by one or more attributes:

- **Status**: Select one or more status values to filter the case list. The options are *Active* and *Closed*.
- **Time case opened**: Select the start and end dates for when the case was opened.
- **Last updated**: Select the start and end dates for when the case was updated.

Investigate a case

Deeper investigation into insider risk management alerts is critical to taking proper corrective actions. Insider risk management cases are the central management tool to dive deeper into user risk activity history and alert details, and to explore the content and messages exposed to risks. Risk analysts and investigators also use cases to centralize review feedback and notes and to process case resolution.

Selecting a case opens the case management tools and allows analysts and investigators to dig into the details of cases.

Case overview

The **Case overview** tab summarizes the alert activity and risk level history for the case.

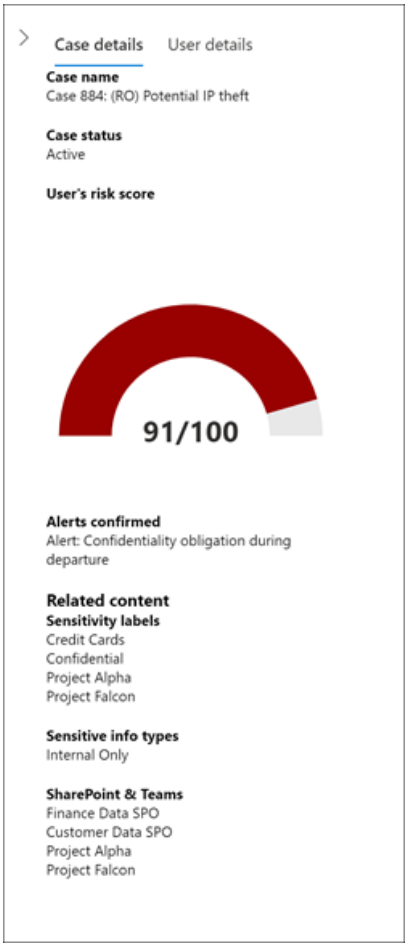
- The **Alerts** widget shows the policy matches for the case, including the status of the alert, the alert risk severity, and when the alert was detected.
- The **Risk level history** chart displays the user risk level over the last 30 days. The line chart allows analysts

and investigators to quickly see the trend in overall user risk over time.

- The **Risk activity content** widget summarizes the types of data and content contained in alerts added to the case. This widget gives an all-up view of the entire data and content set at risk in the case.

The **Case details** pane is available on all case management tabs and summarizes the case details for risk analysts and investigators. It includes the following areas:

- **Case name**: The name of the case, prefixed with an autogenerated case sequence number and the name of the risk associated with the policy template that the first confirmed alert matches.
- **Case status**: The current status of the case, either *Active* or *Closed*.
- **User's risk score**: The current calculated risk level of the user for the case. This score is calculated every 24 hours and uses the alert risk scores from all active alerts associated to the user.
- **Alerts confirmed**: List of alerts for the user confirmed for the case.
- **Related content**: List of content, sorted by content sources and types. For example, for case alert content in SharePoint Online, you may see folder or file names listed that are associated with the risk activity for alerts in the case.



Alerts

The **Alerts** tab summarizes the current alerts included in the case. New alerts may be added to an existing case and they will be added to the **Alert** queue as they are assigned. The following alert attributes are listed the queue:

- Status
- Severity
- Time detected

Select an alert from the queue to display the **Alert detail** page.

Use the search control to search alert names for specific text and use the alert filter to sort cases by the

following attributes:

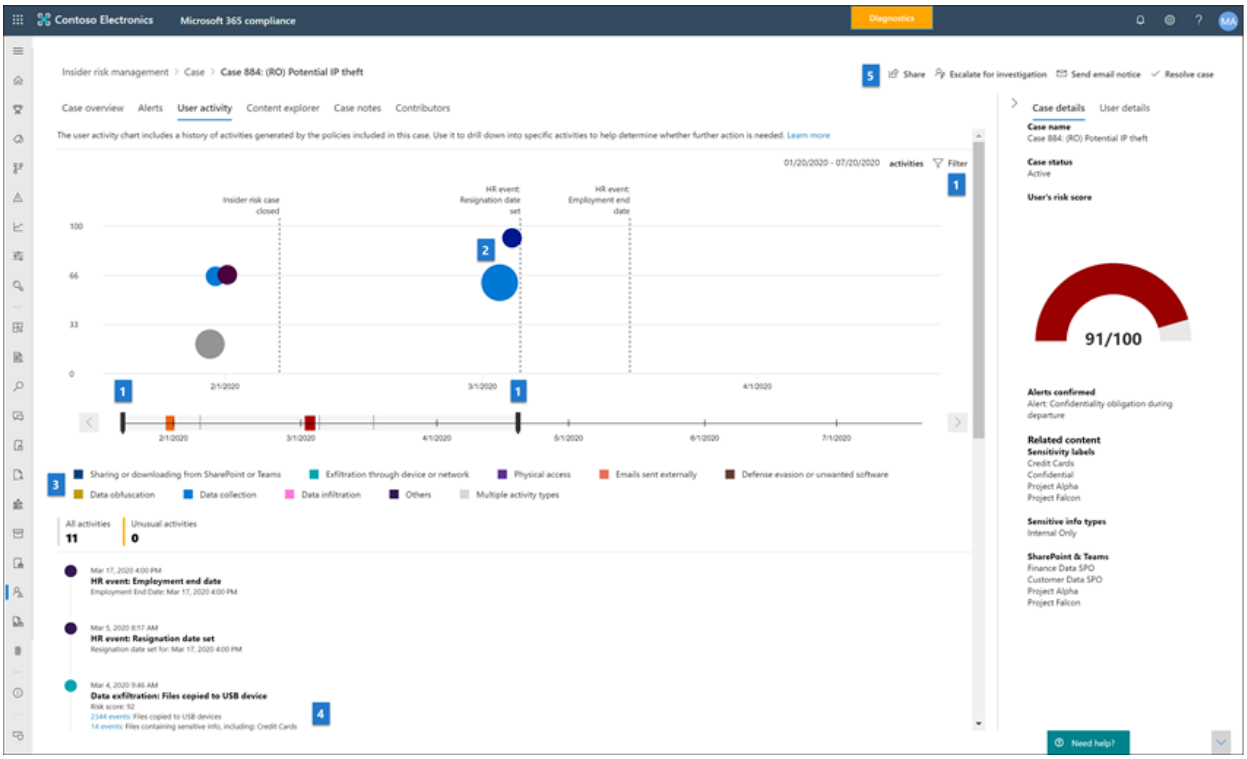
- Status
- Severity
- Time detected, start date, and end date

Use the filter control to filter alerts by several attributes, including:

- **Status**: Select one or more status values to filter the alert list. The options are *Confirmed*, *Dismissed*, *Needs review*, and *Resolved*.
- **Severity**: Select one or more alert risk severity levels to filter the alert list. The options are *High*, *Medium*, and *Low*.
- **Time detected**: Select the start and end dates for when the alert was created.
- **Policy**: Select one or more policies to filter the alerts generated by the selected policies.

User activity

The **User activity** tab is one of the most powerful tools for internal risk analysis and investigation for cases in the insider risk management solution. This tab is structured to enable quick review of a case, including a historical timeline of all alerts, all alerts details, the current risk score for the user in the case, and controls to take effective action to contain the risks in the case.



1. **Date and window time filters**: By default, the last six months of alerts confirmed in the case are displayed in the User activity chart. You can easily filter the chart view with either the slider controls at both ends of the chart window, or by defining specific start and end dates in the chart filter control.
2. **Risk alert activity and details**: Risk activities are visually displayed as colored bubbles in the User activity chart. Bubbles are created for different categories of risk and bubble size is proportional to the number of risk activities for the category. Select a bubble to display the details for each risk activity. Details include:
   - **Date** of the risk activity.
   - The **risk activity category**. For example, *Email(s) with attachments sent outside the organization* or *File(s) downloaded from SharePoint Online*.
   - **Risk score** for the alert. This score is the numerical score for the alert risk severity level.
   - Number of events associated with the alert. Links to each file or email associated with the risk activity is also available.

3. **Risk activity legend**: Across the bottom of the user activity chart, a color-coded legend helps you quickly determine risk category for each alert.
4. **Risk activity chronology**: The full chronology of all risk alerts associated with the case are listed, including all the details available in the corresponding alert bubble.
5. **Case actions**: Options for resolving the case are on the case action toolbar. You can resolve a case, send an email notice to the user, or escalate the case for a data or user investigation.

Activity explorer (preview)

> **IMPORTANT**
> The Activity explorer tab is available in the case management area for users with triggering events after this feature is available in your organization.

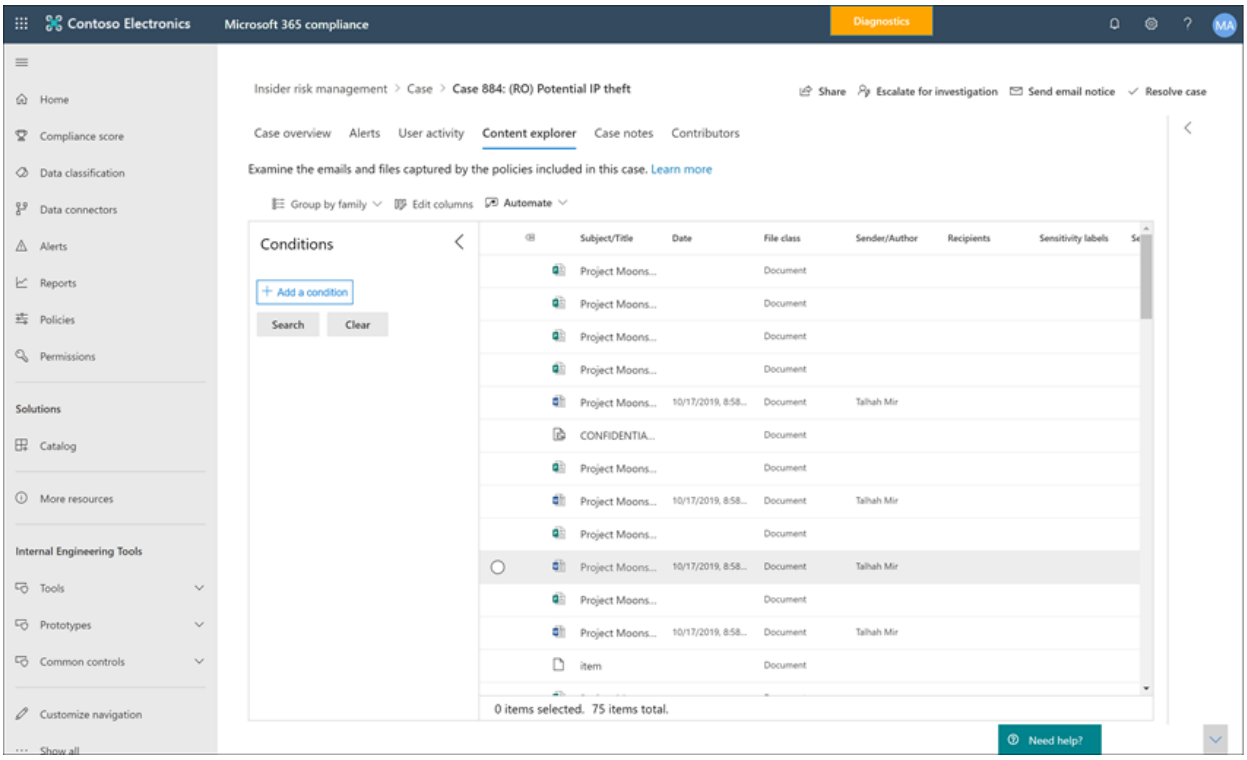
The **Activity explorer** tab allows risk analysts and investigators to review activity details associated with risk alerts. For example, as part of the case management actions, investigators and analysts may need to review all the risk activities associated with the case for more details. With the **Activity explorer**, reviewers can quickly review a timeline of detected risky activity and identify and filter all risk activities associated with alerts.

For more information about the Activity explorer, see the Insider risk management alerts article.

Content Explorer

The **Content Explorer** tab allows risk analysts and investigators to review copies of all individual files and email messages associated with risk alerts. For example, if an alert is created when a user downloads hundreds of files from SharePoint Online and the activity triggers a policy alert, all the downloaded files for the alert are captured and copied to the insider risk management case from original storage sources.

The Content Explorer is a powerful tool with basic and advanced search and filtering features. To learn more about using the Content Explorer, see Insider risk management Content Explorer.



Case notes

The **Case notes** tab in the case is where risk analysts and investigators share comments, feedback, and insights about their work for the case. Notes are permanent additions to a case and cannot be edited or deleted after the note is saved. When a case is created from an alert, the comments entered in the **Confirm alert and create**

insider risk case dialog are automatically added as a case note.

The case notes dashboard displays notes by the user that created the note and the time that has passed since the note was saved. To search the case note text field for a specific keyword, use the **Search** button on the case dashboard and enter a specific keyword.

To add a note to a case:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Cases** tab.
2. Select a case, then select the **Case notes** tab.
3. Select **Add case note**.
4. On the **Add case note** dialog, type your note for the case. Select **Save** to add the note to the case or select **Cancel** close without saving the note to the case.

Contributors

The **Contributors** tab in the case is where risk analysts and investigators can add other reviewers to the case. Be default, all users assigned the **Insider Risk Management Analysts** and **Insider Risk Management Investigators** roles are listed as contributors for each active and closed case. Only users assigned the **Insider Risk Management Investigators** role have permission to view files and messages in the Content Explorer.

Temporary access to a case can be granted by adding a user as a contributor. Contributors have all case management control on the specific case except:

- Permission to confirm or dismiss alerts
- Permission to edit the contributors for cases
- Permission to view files and messages in the Content Explorer

To add a contributor to a case:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Cases** tab.
2. Select a case, then select the **Contributors** tab.
3. Select **Add contributor**.
4. On the **Add contributor** dialog, start typing the name of the user you want to add and then select the user from the suggested user list. This list is generated from the Azure Active Directory of your tenant subscription.
5. Select **Add** to add the user as a contributor or select **Cancel** close the dialog without adding the user as a contributor.

Case actions

Risk analysts and investigators can take action on a case in one of several methods, depending on the severity of the case, the history of risk of the user, and the risk guidelines of your organization. In some situations, you may need to escalate a case to a user or data investigation to collaborate with other areas of your organization and to dive deeper into risk activities. Insider risk management is tightly integrated with other Microsoft 365 compliance solutions to help you with end-to-end resolution management.

Send email notice

In most cases, user actions that create insider risk alerts are inadvertent or accidental. Sending a reminder notice to the user via email is an effective method for documenting case review and action, and is a method to remind users of corporate policies or point them to refresher training. Notices are generated from notice templates that you create for your insider risk management infrastructure.

It's important to remember that sending an email notice to a user ***does not*** resolve the case as *Closed*. In some cases, you may want to leave a case open after sending a notice to a user to look for more risk activities without opening a new case. If you want to resolve a case after sending a notice, you must select the **Resolve case** as a

follow-on step after sending a notice.

To send a notice to the user assigned to a case:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Cases** tab.
2. Select a case, then select the **Send email notice** button on the case action toolbar.
3. On the **Send e-mail notice** dialog, select the **Choose a notice template** dropdown control to select the notice template for the notice. This selection pre-fills the other fields on the notice.
4. Review the notice fields and update as appropriate. The values entered here will override the values on the template.
5. Select **Send** to send the notice to the user or select **Cancel** close the dialog without sending the notice to the user. All sent notices are added to the case notes queue on the **Case notes** dashboard.

Escalate for investigation

Escalate the case for user investigation in situations where additional legal review is needed for the user's risk activity. This escalation opens a new Advanced eDiscovery case in your Microsoft 365 organization. Advanced eDiscovery provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external legal investigations. It also lets your legal team manage the entire legal hold notification workflow to communicate with custodians involved in a case. Assigning a reviewer as a custodian in an Advanced eDiscovery case created from an insider risk management case helps your legal team take appropriate action and manage content preservation. To learn more about Advanced eDiscovery cases, see Overview of Advanced eDiscovery in Microsoft 365.

To escalate a case to a user investigation:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Cases** tab.
2. Select a case, then select the **Escalate for investigation** button on the case action toolbar.
3. On the **Escalate for investigation** dialog, enter a name for the new user investigation. If needed, enter notes about the case and select **Escalate**.
4. Review the notice fields and update as appropriate. The values entered here will override the values on the template.
5. Select **Confirm** to create the user investigation case or select **Cancel** to close the dialog without creating a new user investigation case.

After the insider risk management case has been escalated to a new user investigation case, you can review the new case in the **eDiscovery** > **Advanced** area in the Microsoft 365 compliance center.

Run automated tasks with Power Automate flows for the case

Using recommended Power Automate flows, risk investigators and analysts can quickly take action to:

- Request information from HR or business about a user in an insider risk case
- Notify manager when a user has an insider risk alert
- Add calendar reminder to follow up on an insider risk case
- Create a record for an insider risk management case in ServiceNow

To run, manage, or create Power Automate flows for an insider risk management case:

1. Select **Automate** on the case action toolbar.
2. Choose the Power Automate flow to run, then select **Run flow**.
3. After the flow has completed, select **Done**.

To learn more about Power Automate flows for insider risk management, see Getting started with insider risk management settings.

View or create a Microsoft Teams team for the case

When Microsoft Teams integration for insider risk management is enabled in settings, a Microsoft Teams team is automatically created every time an alert is confirmed and a case is created. Risk investigators and analysts can quickly open Microsoft Teams and navigate directly to the team for a case by selecting **View Microsoft Teams team** on the case action toolbar.

For cases opened before enabling Microsoft Team integration, risk investigators and analysts can create a new Microsoft Teams team for a case by selecting **Create Microsoft Teams team** on the case action toolbar.

When a case is resolved, the associated Microsoft Team will be automatically archive (hidden and turned to read-only).

To learn more about Microsoft Teams for insider risk management, see Getting started with insider risk management settings.

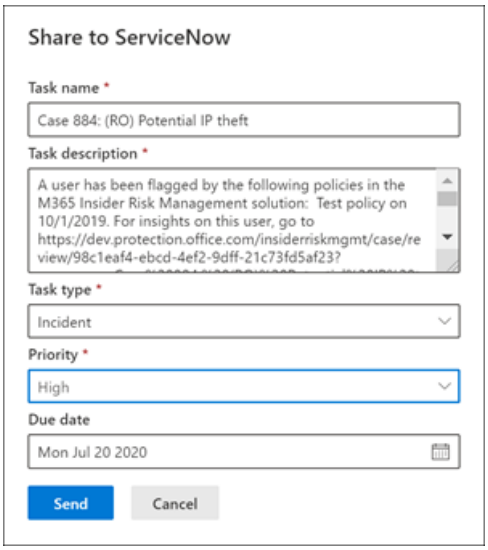
Share the case

Sharing an insider risk management case allows risk investigators and analysts to easily collaborate with other compliance stakeholders in your organization. You can quickly share a link to an insider risk management case with external stakeholders from the case management area. To access the insider risk management case from the link, stakeholders must be included in any of the insider risk management role groups.

> **NOTE**
> Thank you for your feedback and support during the preview of the ServiceNow connector. We've decided to end the preview of ServiceNow connector and discontinue support in insider risk management on November 30, 2020. We are actively evaluating alternative methods to provide customers with ServiceNow integration in insider risk management.

The following sharing options are available:

- **ServiceNow**: After configuring the Microsoft 365 ServiceNow connector for your Microsoft 365 organization, you can easily share a link to the case, open an incident, or request a change with your ServiceNow organization. To share the case with ServiceNow, select **Share** > **ServiceNow** from the case action. ServiceNow integration with insider risk management supports includes the following case information and actions:
  - **Task name**: The name for the new ServiceNow task.
  - **Task description**: The description for the new ServiceNow task. This editable description field automatically includes a link to the insider risk management case.
  - **Task type**: The task type for the new ServiceNow task, either *Incident* or *Change request*.
  - **Priority**: The priority for the new ServiceNow task, either *Planning*, *Low*, *Moderate*, *High*, or *Critical*.
  - **Due date**: The requested date for completing the ServiceNow task.



- **Email**: Shares a link to the insider risk management case in an email. You can choose any locally configured email client with this sharing option. To share the case link with email, select **Share** > **Email** from the case action toolbar.
- **Copy link**: Copies a link to the insider risk management case to your clipboard. To copy the case link to your clipboard, select **Share** > **Copy link** from the case action toolbar.

Resolve the case

After risk analysts and investigators have completed their review and investigation, a case can be resolved to act on all the alerts currently included in the case. Resolving a case adds a resolution classification, changes the case status to *Closed*, and the resolution action reasons are automatically added to the case notes queue on the **Case notes** dashboard. Cases are resolved as either:

- **Benign**: The classification for cases where policy match alerts are evaluated as low risk, non-serious, or false positive.
- **Confirmed policy violation**: The classification for cases where policy match alerts are evaluated as risky, serious, or the result of malicious intent.

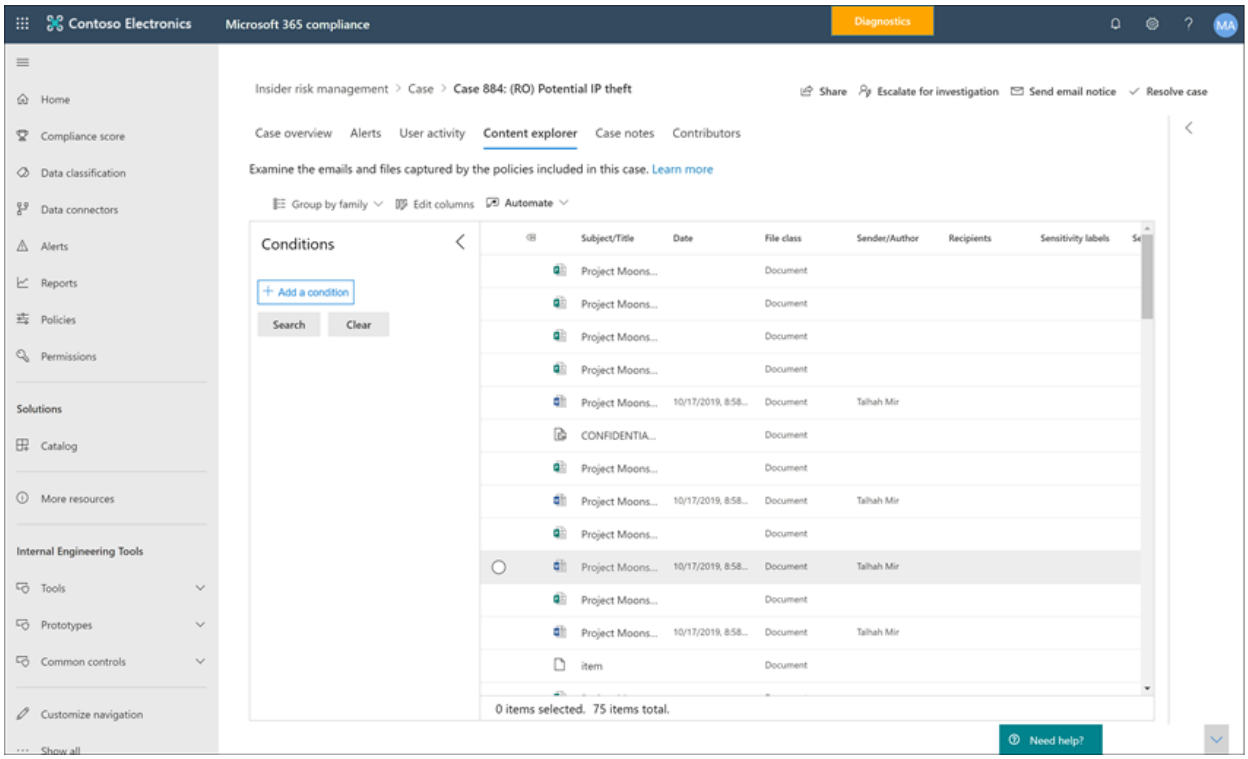
To resolve a case:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Cases** tab.
2. Select a case, then select the **Resolve case** button on the case action toolbar.
3. On the **Resolve case** dialog, select the **Resolve as** dropdown control to select the resolution classification for the case. The options are **Benign** or **Confirmed policy violation**.
4. On the **Resolve case** dialog, enter the reasons for the resolution classification in the **Action taken** text field.
5. Select **Resolve** to close the case or select **Cancel** close the dialog without resolving the case.

Insider risk management Content Explorer

2/18/2021 • 11 minutes to read • Edit Online

The insider risk management Content Explorer allows users assigned the *Insider Risk Management Investigators* role to examine the context and details of content associated with activity in alerts. For all alerts that are confirmed to a case, copies of data and message files are archived as a snapshot in time of the items, while maintaining the original files and messages in the storage sources. The copying of data and messages is transparent to the user associated with the alert and to the owner of the content. If the content includes Information Rights management permissions, these permissions are maintained for the copied content and users assigned the *Insider Risk Management Investigators* role will need these permissions and rights if they need to open and view the files. Each file and message are automatically assigned a unique file ID in the insider risk management case for management purposes. Documents associated with device indicator activities are not included in Content Explorer.



Column options

To make it easier for risk analysts and investigators to review captured data and messages and review the context to the case, several filtering and sorting tools are included in the Content Explorer. For basic sorting, the **Date** and **File class** columns support sorting using the column titles in the content queue pane. Other queue columns are available to add to the view to provide different pivots on the files and messages.

To add or remove column headings for the content queue, use the **Edit columns** control and select from the following column options. These columns map to the common, email, and document property conditions supported in the Content Explorer and listed later in this article.

COLUMN OPTION	DESCRIPTION

COLUMN OPTION	DESCRIPTION
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document will still retain the original author.
Bcc	Available for email messages, the users in the Bcc message field.
Cc	Available for email messages, the users in the Cc message field.
Compound path	Human readable path that describes the source of the item.
Conversation ID	Conversation Id from the message.
Conversation index	Conversation index from the message.
Created time	The time the file or email message was created.
Date	For email, the date a message was received by a recipient or sent by the sender. For documents, the date a document was last modified.
Dominant theme	Dominant theme as calculated for analytics.
Email set ID	Group ID for all messages in the same email set.
Family ID	Family Id groups together all items; for email, this column includes the message and all attachments; for documents, this column includes the document and any embedded items.
File class	For content from SharePoint and OneDrive: **Document**; for content from Exchange: **Email or **Attachment**.
File ID	Document identifier unique within the case.
File type icon	The extension of a file; for example, docx, one, pptx, or xlsx. This field is the same property as the FileExtension site property.
ID	The GUID identifier for the file.
Immutable ID	Immutable Id as stored in Office 365.
Inclusive type	Inclusive type calculated for analytics: **0** - not inclusive; **1** - inclusive; **2** - inclusive minus; **3** - inclusive copy.
Last modified	The date that a document was last changed.
Marked as representative	One document from each set of exact duplicates is marked as representatives.

COLUMN OPTION	DESCRIPTION
Message kind	The type of email message to search for. Possible values: contacts, docs, email, external data, faxes, im, journals, meetings, microsoft teams (returns items from chats, meetings, and calls in Microsoft Teams), notes, posts, rssfeeds, tasks, voicemail
Participants	List of all participants of a message; for example, Sender, To, Cc, Bcc.
Pivot ID	The ID of a pivot.
Received	The date that an email message was received by a recipient. This field is the same property as the Received email property.
Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc.
Representative ID	Numeric identifier of each set of exact duplicates.
Sender	The sender of an email message.
Sender/Author	For email, the person who sent a message. For documents, the person cited in the author field from Office documents. You can type more than one name, separated by commas. Two or more values are logically connected by the OR operator.
Sent	The date that an email message was sent by the sender. This field is the same property as the Sent email property.
Size	For both email and documents, the size of the item (in bytes).
Subject	The text in the subject line of an email message.
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. As previously explained, the Title property is metadata specified in Microsoft Office documents. You can type the name of more than one subject/title, separated by commas. Two or more values are logically connected by the OR operator.
Themes list	Themes list as calculated for analytics.
Title	The title of the document. The Title property is metadata that's specified in Office documents. It's different than the file name of the document.
To	The recipient of an email message in the To field.

Advanced search conditions

You can add search conditions to narrow the scope of a search and return a more refined set of results. Each

condition adds a clause to the search query that is created and run when you start the search. A condition is logically connected to the keyword query (specified in the keyword box) by a logical operator (which is represented as c:c) that is similar in functionality to the AND operator. That means that items have to satisfy both the keyword query and one or more conditions to be included in the search results. This functionality is how conditions help to narrow your results.

For advanced filter and search tools, expand the **Filter** pane on the left side of the content queue. Select the **Add a condition** button to open the condition list:

Operators used with conditions

OPERATOR	QUERY EQUIVALENT	DESCRIPTION
After	`property>date`	Used with date conditions. Returns items that were sent, received, or modified after the specified date.
Before	`property<date`	Used with date conditions. Returns items that were sent, received, or modified before the specified date.
Between	`date..date`	Use with date and size conditions. When used with a date condition, returns items there were sent, received, or modified within the specified date range. When used with a size condition, returns items whose size is within the specified range.
Contains all of	`(property:value) OR (property:value)`	Used with conditions for properties that specify a string value. Returns items that contain all of one or more specified string values.
Contains any of	`(property:value) OR (property:value)`	Used with conditions for properties that specify a string value. Returns items that contain any part of one or more specified string values.
Contains none of	`-property:value` `NOT property:value`	Used with conditions for properties that specify a string value. Returns items that don't contain any part of the specified string value.
Doesn't equal any of	`-property=value` `NOT property=value`	Used with conditions for properties that specify a string value. Returns items that don't contain the specific string.
Equals	`size=value`	Returns items that are equal to the specified size.[1]
Equals any of	`(property=value) OR (property=value)`	Used with conditions for properties that specify a string value. Returns items that are an exact match of one or more specified string values.

OPERATOR	QUERY EQUIVALENT	DESCRIPTION
Equals none of	`(property=value) OR (property=value)`	Used with conditions for properties that specify a string value. Returns items that do not match one or more specified string values.
Greater than	`size>value`	Returns items where the specified property is greater than the specified value.[1]
Greater or equal	`size>=value`	Returns items where the specified property is greater than or equal to the specified value.[1]
Less than	`size<value`	Returns items that are greater than or equal to the specific value.[1]
Less or equal	`size<=value`	Returns items that are greater than or equal to the specific value.[1]
Not equal	`size<>value`	Returns items that don't equal the specified size.[1]

NOTE

[1] This operator is available only for conditions that use the Size property.

Common property conditions

CONDITION OPTION	DESCRIPTION
Date	For email, the date a message was received by a recipient or sent by the sender. For documents, the date a document was last modified.
Sender/Author	For email, the person who sent a message. For documents, the person cited in the author field from Office documents. You can type more than one name, separated by commas. Two or more values are logically connected by the **OR** operator.
Size	For both email and documents, the size of the item (in bytes).
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. The Title property in documents is metadata specified in Microsoft Office documents. You can type the name of more than one subject/title, separated by commas. Two or more values are logically connected by the OR operator.

Email property conditions

The following table lists email message property conditions available the Content Explorer.

CONDITION OPTION	DESCRIPTION
Bcc	The Bcc field of an email message.
Cc	The Cc field of an email message.
Email security	Security setting of the message.
Email sensitivity	Sensitivity setting of the message.
Email set ID	Group ID for all messages in the same email set.
From	The sender of an email message.
Has attachment	Indicates whether a message has an attachment. Use the values **true** or **false**.
Importance	The importance of an email message, which a sender can specify when sending a message. By default, messages are sent with normal importance, unless the sender sets the importance as **high** or **low**.
Meeting end date	Meeting end date for meetings.
Meeting start date	Meeting start date for meetings.
Message kind	The type of email message to search for. Possible values: contacts, docs, email, external data, faxes, im, journals, meetings, microsoft teams (returns items from chats, meetings, and calls in Microsoft Teams), notes, posts, rssfeeds, tasks, voicemail
Participant domain	List of all domains of participants of a message.
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc.
Received	The date that an email message was received by a recipient.
Recipient domains	List of all domains of recipients of a message.
Sender	Sender (From) field for message types. Format is **DisplayName <SmtpAddress>**.
Sender domain	Domain of the sender.
Subject	The text in the subject line of an email message. **Note:** When you use the Subject property in a query, the search returns all messages in which the subject line contains the text you're searching for. In other words, the query doesn't return only those messages that have an exact match. For example, if you search for `subject:"Quarterly Financials"`, your results will include messages with the subject "Quarterly Financials 2018".

CONDITION OPTION	DESCRIPTION
To	The To field of an email message.
Unique in email set	False if there's a duplicate of the attachment in its email set.

Document property conditions

The following table lists documents property conditions available the Content Explorer. Many of these property conditions are shared with review sets included in Advanced eDiscovery cases.

CONDITION OPTION	DESCRIPTION
Attorney-client privilege score	Attorney-client privilege model content score.
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document will still retain the original author.
Compliance labels	Compliance labels applied in Office 365.
Compound path	Human readable path that describes the source of the item.
Conversation ID	Conversation Id from the message.
Created time	The time the file or email message was created.
Custodian	Name of the custodian the item was associated with.
Dominant theme	Dominant theme as calculated for analytics.
Family ID	Family Id groups together all items; for email, this field includes the message and all attachments; for documents, this field includes the document and any embedded items.
File class	For content from SharePoint and OneDrive: **Document**; for content from Exchange: **Email or **Attachment**.
File types	The extension of a file; for example, docx, one, pptx, or xlsx.
Has attorney participant	True when at least one of the participants is found in the attorney list; otherwise, the value is False.
Immutable ID	Immutable Id as stored in Office 365.
Inclusive type	Inclusive type calculated for analytics: **0** - not inclusive; **1** - inclusive; **2** - inclusive minus; **3** - inclusive copy.
Item class	Item class supplied by exchange server; for example, **IPM.Note**
Last modified	The date that a document was last changed.

CONDITION OPTION	DESCRIPTION
Load ID	Load Id, in which the item was loaded into a review set.
Location name	String that identifies the source of the item. For exchange, this field will be the SMTP address of the mailbox. For SharePoint and OneDrive, the URL to the site collection.
Marked as representative	One document from each set of exact duplicates is marked as representatives.
Native file extension	Native extension of the item.
Native file name	Native file name of the item.
NdEtSortExclAttach	Concatenation of email set and ND set for efficient sorting at review time; D is added as a prefix to ND sets and E is added to email sets.
Pivot ID	The ID of a pivot.
Potentially privileged	True if attorney-client privilege detection model considers the document potentially privileged.
Processing status	Processing status after the item was added to a review set.
Read percentile	Read percentile for the document based on Relevance.
Relevance score	Relevance score of a document based on Relevance.
Relevance tag	Relevance score of a document based on Relevance.
Representative ID	Numeric identifier of each set of exact duplicates.
Tags	Tags applied in a review set.
Themes list	Themes list as calculated for analytics.
Title	The title of the document. The Title property is metadata that's specified in Office documents. It's different than the file name of the document.
Was remediated	True if the item was remediated, otherwise False.
Word count	The number of words in a file.

Insider risk management Users dashboard

11/2/2020 • 8 minutes to read • Edit Online

The **Users dashboard** is an important tool in the insider risk management workflow and helps investigators and analysts have a more complete understanding of risk activities. This dashboard offers views and management features to meet administrative needs between the creating insider risk management policies and managing insider risk management cases.

After users are added to insider risk management policies, background processes are automatically evaluating user activities for triggering indicators. After triggering indicators are present, user activities are assigned risk scores. Some of these activities may result in an insider risk alert, but some activities may not meet a minimum risk score level and an insider risk alert won't be created. The **Users dashboard** allows you to view users with these types of indicators and risk scores, as well users that have active insider risk alerts.

Additionally, there may be scenarios where you need to add temporarily users to insider risk policies after an unusual event is reported outside of the insider risk management workflow. The **Users dashboard** allows you to manually add a user to an insider risk policy for a specific amount of time and bypass the requirement for a user to have a triggering indicator. These users are always displayed in the Users dashboard when actively assigned to a policy.

Learn more about how the Users dashboard displays users in the following scenarios:

- Dashboard users with active insider risk policy alerts
- Dashboard users with triggering indicators
- Dashboard users added temporarily to policies

Dashboard users with active insider risk policy alerts

The **Users dashboard** automatically displays all users with active insider risk policy alerts. These users with alerts have both a triggering indicator and an activity risk score that meets the requirements for creating an insider risk alert. Activities for these users are viewed by selecting the user in the **Users dashboard** and navigating to the **User activity** tab.

Dashboard users with triggering indicators

The **Users dashboard** automatically displays all users with triggering indicators, but that don't have an activity risk score that would create an insider risk alert. For example, a user with a reported resignation date is displayed because this event is a triggering indicator but isn't an activity that has a risk score. Activities for these users are viewed by selecting the user in the **Users dashboard** and navigating to the **User activity** tab.

Dashboard users added temporarily to policies

The **Users dashboard** allows you to temporarily add users to an existing insider risk management policy after an unusual event outside of the insider risk management workflow. Temporarily adding users is also a way to add users to an insider risk management policy for testing the policy, even if a required connector isn't configured.

When a user is manually added to a policy, the user activities for the previous 90 days are scored and added to the **User activity** timeline. For example, you have a user not currently in-scope in an insider risk policy and the user has data leak activities reported to the legal department in your organization. The legal department recommends that you configure new short-term monitoring requirements for the user. You can temporarily

assign the user to your *Data leaks* policy for a designated length of time (activation window). All users added temporarily are displayed in the **Users dashboard** because triggering indicator requirements are waived.

> **NOTE**
>
> It may take several hours for new manually-added users to appear in the **Users dashboard**. Activities for the previous 90 days for these users may take up to 24 hours to display. To view activities for manually added users, select the user on the **Users dashboard** and open the **User activity** tab on the details pane.

The user is automatically removed from the insider policy and the **Users dashboard** when the time defined in the **Activation window** expires if:

- the user doesn't have any triggering indicators or insider risk policy alerts, and
- if the manually defined **Activation window** duration is longer than the global policy **Activation window** duration.

The **Activation window** setting with the longest duration always overrides the **Activation window** setting with a shorter duration. For example, you've configured the **Activation window** on the global **Policy timeframes** tab in the insider risk management global settings for 15 days, which is automatically applied to all your insider risk policies.

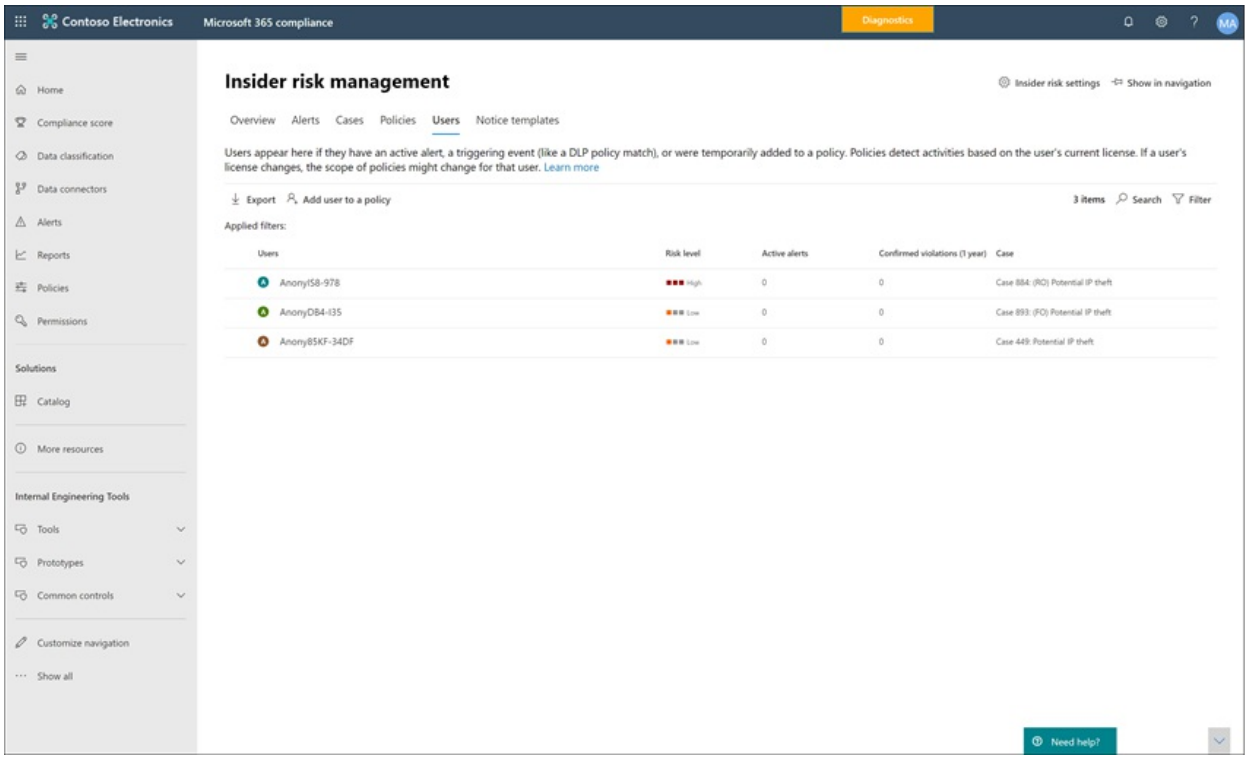
You temporarily add a user to your *Data leaks* insider risk policy and define 30 days as the **Activation window** for this user. The global **Activation window** setting of 15 days is overridden by defining the **Activation window** setting of 30 days for the temporarily added user. The temporarily added user will remain in the **Users dashboard** and be in-scope for the policy for 30 days.

In the opposite scenario where the global **Activation window** setting is longer than the **Activation window** setting defined for a temporarily added user, the global **Activation window** setting would override the **Activation window** setting for the temporarily added user. The temporarily added user will remain in the **Users dashboard** and be in-scope for the policy for the number of days defined in the global **Activation window** settings.

View user information on the Users dashboard

Each user displayed in the **Users dashboard** has the following information:

- **Users**: The username for a user. This field is anonymized if the global anonymization setting for insider risk management is enabled.
- **Risk level**: The current calculated risk level of the user. This score is calculated every 24 hours and uses the alert risk scores from all active alerts associated to the user. For users with only triggering indicators, the risk level is zero.
- **Active alerts**: The number of active alerts for all policies.
- **Confirmed violations**: The number of cases resolved as *confirmed policy violation* for the user.
- **Case**: The current active case for the user.



NOTE

The number of users displayed on the **Users dashboard** may be limited in some instances, depending on the volume of active alerts and matching policies. Users with active alerts are displayed on the **Users dashboard** as the alerts are generated, and there may be rare cases when the maximum number of displayed users is reached. If this happens, users with active alerts who aren't displayed will be added to the **Users dashboard** as existing user alerts are triaged.

View user details

To view more details about risk activity for a user, open the user details pane by double-clicking a user in the **Users dashboard**. On the details pane, you can view the following information:

- **User profile** tab
  - **Name and title**: The name and position title for the user from Azure Active Directory. These user fields will be anonymized or empty if the global anonymization setting for insider risk management is enabled.
  - **User email**: The email address for the user.
  - **Alias**: The network alias for the user.
  - **Organization or department**: The organization or department for the user.
- **User activity** tab
  - **History of recent user activity**: Lists both triggering indicators and insider risk indicators for user activities up to the last 180 days. All activities pertinent to insider risk indicators are also scored, though the activities may or may not have generated an insider risk alert. Triggering indicator examples may be a resignation date or the last scheduled date of work for the user. Insider risk indicators are activities determined to have an element of risk and are defined in policies that the user is included in. Event and risk activities are listed with the most recent item listed first.

Temporarily add a user to a policy

To temporarily add a user to an insider risk management policy, you'll use the **Users** tab in the **Insider risk management** solution in the Microsoft 365 compliance center. Users added manually bypass triggering

indicator requirements for the policy they are added to and are displayed in the **Users dashboard**. To permanently add a user to an insider risk management policy, you'll use the policy wizard.

Complete the following steps to add a user to an existing insider risk policy:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Users** tab.
2. Select **Add a user to a policy** on the toolbar.
3. On the **Add a new user** dialog, start typing a user name in the **User** field. Select the user you want to add to a policy.
4. Select the dropdown arrow for the **Policy** field to display configured insider risk management policies. Select the policy to add the user to.
5. Use the **Activation window** slider control to define how long the user is included in a policy and displayed in the Users dashboard. The time you specify determines how long the policy is active for this user and starts when the first alert is generated or a triggering indicator (like a DLP policy match) is detected. The range for the **Activation window** is 5 to 30 days.
6. Select **Add** and then **Confirm** to add the user to the policy.

> **NOTE**
>
> It may take several hours for new manually-added users to appear in the **Users dashboard**. Activities for the previous 90 days for these users may take up to 24 hours to display. To view activities for manually added users, select the user on the **Users dashboard** and open the **User activity** tab on the details pane.

Run automated tasks with Power Automate flows for a user

Using recommended Power Automate flows, risk investigators and analysts can quickly take action to:

- Notify users when they're added to an insider risk policy

To run, manage, or create Power Automate flows for an insider risk management user:

1. Select **Automate** on the user action toolbar.
2. Choose the Power Automate flow to run, then select **Run flow**.
3. After the flow has completed, select **Done**.

To learn more about Power Automate flows for insider risk management, see Getting started with insider risk management settings.

Insider risk management notice templates

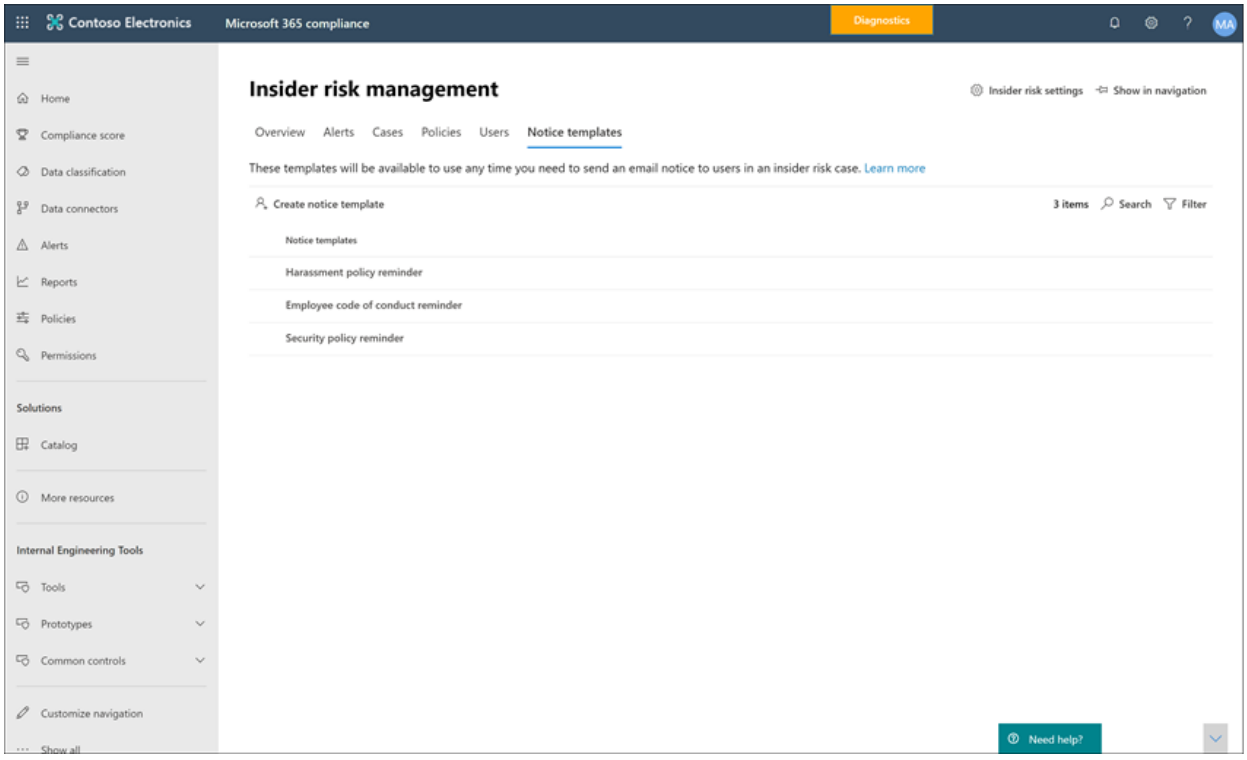
11/2/2020 • 4 minutes to read • Edit Online

Insider risk management notice templates allow you to send email messages to users when their activities generate a policy match and alert. In most cases, user actions that generate alerts are the result of mistakes or inadvertent activities without ill intent. Notices serve as simple reminders to users to be more careful, to provide links to information for refresher training, or to corporate policy resources. Notices can be an important part of your internal compliance training program and can help create a documented audit trail for users with recurring risk activities.

Create notice templates if you want to send users an email reminder notice for policy matches as part of the issue resolution process. Notices can only be sent to the user email address associated with the specific alert being reviewed. When selecting a notice template to apply to a policy match, you can choose to accept the field values defined in the template or overwrite the fields as needed.

Notice templates dashboard

The **Notices templates dashboard** displays a list of configured notice templates and allows you to create new notice templates. The notice templates are listed in reverse date order with the most recent notice template listed first.



HTML for notices

If you'd like to create more than a simple text-based email message for notifications, you can create a more detailed message by using HTML in the message body field of a notice template. The following example provides the message body format for a basic HTML-based email notification template:

```
<!DOCTYPE html>
<html>
<body>
<h2>Action Required: Contoso User Code of Conduct Policy Training</h2>
<p>A recent activity you've performed has generated a risk alert prohibited by the Contoso User <a
href='https://www.contoso.com'>Code of Conduct Policy</a>.</p>
<p>You are required to attend the Contoso User Code of Conduct <a
href='https://www.contoso.com'>training</a> within the next 14 days. Please contact <a
href='mailto:hr@contoso.com'>Human Resources</a> with any questions about this training request.</p>
<p>Thank you,</p>
<p><em>Human Resources</em></p>
</body>
</html>
```

NOTE

HTML href attribute implementation in the insider risk management notice templates currently support only single quotation marks instead of double quotation marks for URL references.

Create a new notice template

To create a new insider risk management notice template, you'll use the notice wizard in **Insider risk management** solution in the Microsoft 365 compliance center.

Complete the following steps to create a new insider risk management notice template:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Notice templates** tab.
2. Select **Create notice template** to open the notice wizard.
3. On the **Create a new notice template** page, complete the following fields:
   - **Template name**: Enter a friendly name for the notice. This name appears on the list of notices on the notice dashboard and in the notice selection list when sending notices from a case.
   - **Send from**: Enter the sender email address for the notice. This address will appear in the **From:** field in all notices sent to users unless changed when sending a notice from a case.
   - **Cc and Bcc** fields: Optional users or groups to be notified of the policy match, selected from the Active Directory for your subscription.
   - **Subject**: Information that appears in the subject line of the message, supports text characters.
   - **Message body**: Information that appears in the message body, supports text or HTML values.
4. Select **Create** to create and save the notice template or select **Cancel** to close without saving the notice template.

Update a notice template

To update an existing insider risk management notice template, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Notice templates** tab.
2. On the notice dashboard, select the notice template you want to manage.
3. On the notice details page, select **Edit**
4. On the **Edit** page, you can edit the following fields:
   - **Template name**: Enter a new friendly name for the notice. This name appears on the list of notices on the notice dashboard and in the notice selection list when sending notices from a case.
   - **Send from**: Update the sender email address for the notice. This address will appear in the **From:**

field in all notices sent to users unless changed when sending a notice from a case.

- **Cc and Bcc** fields: Update optional users or groups to be notified of the policy match, selected from the Active Directory for your subscription.
- **Subject**: Update information that appears in the subject line of the message, supports text characters.
- **Message body**: Update information that appears in the message body, supports text or HTML values.

5. Select **Save** to update and save the notice or select **Cancel** to close without saving the notice template.

Delete a notice template

To delete an existing insider risk management notice template, complete the following steps:

1. In the Microsoft 365 compliance center, go to **Insider risk management** and select the **Notice templates** tab.
2. On the notice dashboard, select the notice template you want to delete.
3. Select the **Delete** icon on the toolbar.
4. To delete the notice template, select **Yes** in the delete dialog. To cancel the deletion, select **Cancel**.

Information barriers in Microsoft 365

2/18/2021 • 2 minutes to read • Edit Online

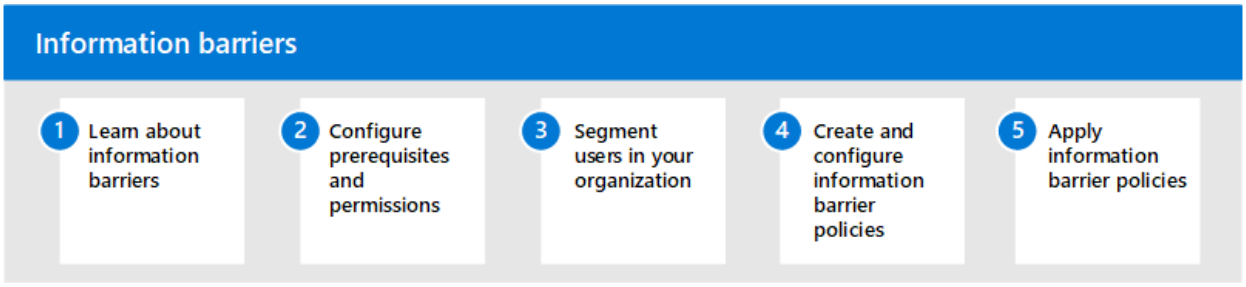
Microsoft 365 enables communication and collaboration across groups and organizations and supports ways to restrict communication and collaboration among specific groups of users when necessary. This may include situations or scenarios where you want to restrict communication and collaboration between two groups to avoid a conflict of interest from occurring in your organization. This may also include situations when you need to restrict communication and collaboration between certain people inside your organization to safeguard internal information.

Information barriers are supported in Microsoft Teams, SharePoint Online, and OneDrive for Business. A compliance administrator or information barriers administrator can define policies to allow or prevent communications between groups of users in Microsoft Teams. Information barrier policies can be used for situations like these:

- User in the day trader group should not communicate or share files with the marketing team
- Finance personnel working on confidential company information should not communicate or share files with certain groups within their organization
- An internal team with trade secret material should not call or chat online with people in certain groups within their organization
- A research team should only call or chat online with a product development team

Configure information barriers for Microsoft 365

Use the following steps to configure information barriers for your organization:



1. Learn about information barriers in Microsoft 365
2. Configure prerequisites and permissions
3. Segment users in your organization
4. Create and configure information barrier policies
5. Apply information barrier policies

More information about information barriers

- Attributes for information barrier policies
- Edit or remove information barrier policies

Learn about information barriers in Microsoft 365

2/18/2021 • 4 minutes to read • Edit Online

Microsoft cloud services include powerful communication and collaboration capabilities. But suppose that you want to restrict communication and collaboration between two groups to avoid a conflict of interest from occurring in your organization. Or, perhaps you want to restrict communication and collaboration between certain people inside your organization in order to safeguard internal information. Microsoft 365 enables communication and collaboration across groups and organizations, so is there a way to restrict communication and collaboration among specific groups of users when necessary? With information barriers, you can!

Microsoft Teams, SharePoint Online, and OneDrive for Business support information barriers. Assuming your subscription includes information barriers, a compliance administrator, or information barriers administrator can define policies to allow or prevent communications between groups of users in Microsoft Teams. Information barrier policies can be used for situations like these:

- User in the day trader group should not communicate or share files with the marketing team
- Finance personnel working on confidential company information should not communicate or share files with certain groups within their organization
- An internal team with trade secret material should not call or chat online with people in certain groups within their organization
- A research team should only call or chat online with a product development team
- A site for day trader group should not be shared or accessed by anyone outside the day trader group

> **IMPORTANT**
>
> Information barriers ***only supports*** two way restrictions. One way restrictions, such as marketing can communicate and collaborate with day traders, but day traders cannot communicate and collaborate with marketing ***is not supported***.

For all of these example scenarios (and more), information barrier policies can be defined to prevent or allow communications and collaboration in Microsoft Teams, SharePoint Online and OneDrive. Such policies can prevent people from calling or chatting with those they shouldn't, or enable people to communicate only with specific groups in Microsoft Teams. With information barrier policies in effect, whenever users who are covered by those policies attempt to communicate and collaborate with others in Microsoft Teams, SharePoint Online or OneDrive checks are done to prevent (or allow) communication and collaboration (as defined by information barrier policies).

To learn more about the user experience with information barriers, see:

- Information barriers in Microsoft Teams
- Information barriers in SharePoint Online
- Information barriers in OneDrive

> **IMPORTANT**
>
> Currently, information barriers do not apply to email communications. In addition, information barriers are independent from compliance boundaries.
>
> Before you define and apply information barrier policies, make sure your organization does not have Exchange address book policies in effect. (Information barriers are based on address book policies.)

What happens with information barriers

When information barrier policies are in place, people who should not communicate or share files with other specific users won't be able to find, select, chat, or call those users. With information barriers, checks are in place to prevent unauthorized communication and collaboration.

Information barriers applies to Microsoft Teams (chats and channels), SharePoint Online and OneDrive. In Microsoft Teams, information barrier policies determine and prevent the following kinds of unauthorized communications:

- Searching for a user
- Adding a member to a team
- Starting a chat session with someone
- Starting a group chat
- Inviting someone to join a meeting
- Sharing a screen
- Placing a call
- Sharing a file with another user
- Access to file through sharing link

If the people involved are included in an information barrier policy to prevent the activity, they will not be able to proceed. In addition, potentially, everyone included in an information barrier policy can be blocked from communicating with others in Microsoft Teams. When people affected by information barrier policies are part of the same team or group chat, they might be removed from those chat sessions and further communication with the group might not be allowed.

To learn more about the user experience with information barriers, see information barriers in Microsoft Teams.

In SharePoint Online and OneDrive, information barrier policies determine and prevent the following kinds of unauthorized collaborations:

- Adding a member to a site
- Accessing site or content by a user
- Sharing site or content with another user
- Searching a site

To learn more about the user experience with information barriers, see information barriers in SharePoint Online

Required licenses and permissions

Information barriers are rolling out now, and are included in subscriptions, such as:

- Microsoft 365 E5/A5
- Office 365 E5/A5
- Office 365 Advanced Compliance
- Microsoft 365 Compliance E5/A5
- Microsoft 365 Insider Risk Management

For more information, see Microsoft 365 licensing guidance for security & compliance.

To define or edit information barrier policies, you must be assigned one of the following roles:

- Microsoft 365 global administrator
- Office 365 global administrator
- Compliance administrator

- IB Compliance Management

(To learn more about roles and permissions, see Permissions in the Office 365 Security & Compliance Center.)

You must be familiar with PowerShell cmdlets in order to define, validate, or edit information barrier policies. Although we provide several examples of PowerShell cmdlets in the how-to article, you'll need to know other details, such as parameters, for your organization.

Next steps

- Learn more about information barriers in Microsoft Teams
- Learn more about information barriers in SharePoint Online
- Learn more about information barriers in OneDrive
- See the attributes that can be used for information barrier policies
- Define policies for information barriers
- Edit (or remove) information barrier policies

Define information barrier policies

2/18/2021 • 16 minutes to read • Edit Online

With information barriers, you can define policies that are designed to prevent certain segments of users from communicating with each other, or allow specific segments to communicate only with certain other segments. Information barrier policies can help your organization maintain compliance with relevant industry standards and regulations, and avoid potential conflicts of interest. To learn more, see Information barriers.

This article describes how to plan, define, implement, and manage information barrier policies. Several steps are involved, and the work flow is divided into several parts. Make sure to read through the prerequisites and the entire process before you begin defining (or editing) information barrier policies.

> **TIP**
> This article includes an example scenario and a downloadable Excel workbook to help you plan and define your information barrier policies.

Concepts of information barrier policies

When you define policies for information barriers, you'll work with user account attributes, segments, "block" and/or "allow" policies, and policy application.

- User account attributes are defined in Azure Active Directory (or Exchange Online). These attributes can include department, job title, location, team name, and other job profile details.
- Segments are sets of users that are defined in the Security & Compliance Center using a selected **user account attribute**. (See the list of supported attributes.)
- Information barrier policies determine communication limits or restrictions. When you define information barrier policies, you choose from two kinds of policies:
  - "Block" policies prevent one segment from communicating with another segment.
  - "Allow" policies allow one segment to communicate with only certain other segments.
- Policy application is done after all information barrier policies are defined, and you are ready to apply them in your organization.

The work flow at a glance

PHASE	WHAT'S INVOLVED
Make sure prerequisites are met	- Verify that you have the required licenses and permissions - Verify that your directory includes data for segmenting users - Enable scoped directory search for Microsoft Teams - Make sure audit logging is turned on - Make sure no Exchange address book policies are in place - Use PowerShell (examples are provided) - Provide admin consent for Microsoft Teams (steps are included)

PHASE	WHAT'S INVOLVED
Part 1: Segment users in your organization	- Determine what policies are needed - Make a list of segments to define - Identify which attributes to use - Define segments in terms of policy filters
Part 2: Define information barrier policies	- Define your policies (do not apply yet) - Choose from two kinds (block or allow)
Part 3: Apply information barrier policies	- Set policies to active status - Run the policy application - View policy status
(As needed) Edit a segment or a policy	- Edit a segment - Edit or remove a policy - Rerun the policy application - View policy status
(As needed) Troubleshooting	- Take action when things are not working as expected

Prerequisites

In addition to the required licenses and permissions, make sure that the following requirements are met:

- Directory data - Make sure that your organization's structure is reflected in directory data. To take this action, make sure that user account attributes, such as group membership, department name, etc. are populated correctly in Azure Active Directory (or Exchange Online). To learn more, see the following resources:
  - Attributes for information barrier policies
  - Add or update a user's profile information using Azure Active Directory
  - Configure user account properties with Office 365 PowerShell
- Scoped directory search - Before you define your organization's first information barrier policy, you must enable scoped directory search in Microsoft Teams. Wait at least 24 hours after enabling scoped directory search before you set up or define information barrier policies.
- EXO license - IB policies work only if the target users have been assigned an EXO license.
- Audit logging - In order to look up the status of a policy application, audit logging must be turned on. We recommend you enable auditing before you begin to define segments or policies. To learn more, see Turn the audit log search on or off.
- No address book policies - Before you define and apply information barrier policies, make sure no Exchange address book policies are in place. Information barriers are based on address book policies, but the two kinds of policies are not compatible. If you do have such policies, make sure to remove your address book policies first. Once information barrier policies are enabled and you have hierarchical address book enabled, all users ***who are not included*** in an information barrier segment will see the hierarchical address book in Exchange online.
- PowerShell - Currently, information barrier policies are defined and managed in the Office 365 Security & Compliance Center using PowerShell cmdlets. Although several examples are provided in this article, you'll need to be familiar with PowerShell cmdlets and parameters. You will also need the Azure PowerShell module.
  - Connect to Security & Compliance Center PowerShell

- Install the Azure PowerShell module

- Admin consent for information barriers in Microsoft Teams - When your IB policies are in place, they can remove non-IB compliance users from Groups (i.e. Teams channels, which are based on groups). This configuration helps ensure your organization remains compliant with policies and regulations. Use the following procedure to enable information barrier policies to work as expected in Microsoft Teams.

  1. Run the following PowerShell cmdlets:

     ```
     Connect-AzAccount
     $appId="bcf62038-e005-436d-b970-2a472f8c1982"
     $sp=Get-AzADServicePrincipal -ServicePrincipalName $appId
     if ($sp -eq $null) { New-AzADServicePrincipal -ApplicationId $appId }
     Start-Process  "https://login.microsoftonline.com/common/adminconsent?client_id=$appId"
     ```

  2. When prompted, sign in using your work or school account for Office 365.

  3. In the **Permissions requested** dialog box, review the information, and then choose **Accept**.

When all the prerequisites are met, proceed to the next section.

> **TIP**
>
> To help you prepare your plan, an example scenario is included in this article. See Contoso's departments, segments, and policies.
>
> In addition, a downloadable Excel workbook is available to help you plan and define your segments and policies (and create your PowerShell cmdlets). Get the workbook.

Part 1: Segment users

During this phase, you determine what information barrier policies are needed, make a list of segments to define, and then define your segments.

Determine what policies are needed

Considering legal and industry regulations, who are the groups within your organization who will need information barrier policies? Make a list. Are there any groups who should be prevented from communicating with another group? Are there any groups that should be allowed to communicate only with one or two other groups? Think about the policies you need as belonging to one of two groups:

- "Block" policies prevent one group from communicating with another group.
- "Allow" policies allow a group to communicate with only certain other, specific groups.

When you have your initial list of groups and policies, proceed to identify the segments you'll need.

Identify segments

In addition to your initial list of policies, make a list of segments for your organization. Users who will be included in information barrier policies should belong to a segment. Plan your segments carefully as a user can only be in one segment. Each segment can have only one information barrier policy applied.

> **IMPORTANT**
>
> A user can only be in one segment.

Determine which attributes in your organization's directory data you'll use to define segments. You can use *Department*, *MemberOf*, or any of the supported attributes. Make sure that you have values in the attribute you

select for users. See the list of supported attributes for information barriers.

> **IMPORTANT**
>
> **Before you proceed to the next section, make sure your directory data has values for attributes that you can use to define segments.** If your directory data does not have values for the attributes you want to use, then the user accounts must be updated to include that information before you proceed with information barriers. To get help with this, see the following resources:
>
> - Configure user account properties with Office 365 PowerShell
> - Add or update a user's profile information using Azure Active Directory

Define segments using PowerShell

Defining segments does not affect users; it just sets the stage for information barrier policies to be defined and then applied.

1. Use the **New-OrganizationSegment** cmdlet with the **UserGroupFilter** parameter that corresponds to the attribute you want to use.

SYNTAX	EXAMPLE
`New-OrganizationSegment -Name "segmentname" -UserGroupFilter "attribute -eq 'attributevalue'"`	`New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"` In this example, a segment called *HR* is defined using *HR*, a value in the *Department* attribute. The **-eq** portion of the cmdlet refers to "equals." (Alternately, you can use **-ne** to mean "not equals". See Using "equals" and "not equals" in segment definitions.)

   After you run each cmdlet, you should see a list of details about the new segment. Details include the segment's type, who created or last modified it, and so on.

2. Repeat this process for each segment you want to define.

> **IMPORTANT**
>
> **Make sure that your segments do not overlap.** Each user who will be affected by information barriers should belong to one (and only one) segment. No user should belong to two or more segments. (See Example: Contoso's defined segments in this article.)

After you have defined your segments, proceed to define information barrier policies.

Using "equals" and "not equals" in segment definitions

In the following example, we are defining a segment such that "Department equals HR."

EXAMPLE	NOTE
`New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"`	Notice that in this example, the segment definition includes an "equals" parameter denoted as **-eq**.

You can also define segments using a "not equals" parameter, denoted as **-ne**, as shown in the following table:

SYNTAX	EXAMPLE

SYNTAX	EXAMPLE
`New-OrganizationSegment -Name "NotSales" -UserGroupFilter "Department -ne 'Sales'"`	In this example, we defined a segment called *NotSales* that includes everyone who is not in *Sales*. The **-ne** portion of the cmdlet refers to "not equals".

In addition to defining segments using "equals" or "not equals", you can define a segment using both "equals" and "not equals" parameters. You can also define complex group filters using logical *AND* and *OR* operators.

SYNTAX	EXAMPLE
`New-OrganizationSegment -Name "LocalFTE" -UserGroupFilter "Location -eq 'Local'" -and "Position -ne 'Temporary'"`	In this example, we defined a segment called *LocalFTE* that includes people who are located locally and whose positions are not listed as *Temporary*.
`New-OrganizationSegment -Name "Segment1" -UserGroupFilter "MemberOf -eq 'group1@contoso.com'' -and MemberOf -ne 'group3@contoso.com'"`	In this example, we defined a segment called *Segment1* that includes people who are members of group1@contoso.com and not members of group3@contoso.com.
`New-OrganizationSegment -Name "Segment2" -UserGroupFilter "MemberOf -eq 'group2@contoso.com' -or MemberOf -ne 'group3@contoso.com'"`	In this example, we defined a segment called *Segment2* that includes people who are members of group2@contoso.com and not members of group3@contoso.com.
`New-OrganizationSegment -Name "Segment1and2" -UserGroupFilter "(MemberOf -eq 'group1@contoso.com' -or MemberOf -eq 'group2@contoso.com') -and MemberOf -ne 'group3@contoso.com'"`	In this example, we defined a segment called *Segment1and2* that includes people members of group1@contoso.com and group2@contoso.com and not members of group3@contoso.com.

TIP

If possible, use segment definitions that include "-eq" or "-ne". Try not to define complex segment definitions.

Part 2: Define information barrier policies

Determine whether you need to prevent communications between certain segments, or limit communications to certain segments. Ideally, you'll use the minimum number of policies to ensure your organization is compliant with legal and industry requirements.

With your list of user segments and the information barrier policies you want to define, select a scenario, and then follow the steps.

- Scenario 1: Block communications between segments
- Scenario 2: Allow a segment to communicate only with one other segment

IMPORTANT

Make sure that as you define policies, you do not assign more than one policy to a segment. For example, if you define one policy for a segment called *Sales*, do not define an additional policy for *Sales*.

In addition, as you define information barrier policies, make sure to set those policies to inactive status until you are ready to apply them. Defining (or editing) policies does not affect users until those policies are set to active status and then applied.

(See Example: Contoso's information barrier policies in this article.)

Scenario 1: Block communications between segments

When you want to block segments from communicating with each other, you define two policies: one for each direction. Each policy blocks communication one way only.

For example, suppose you want to block communications between Segment A and Segment B. In this case, you define one policy preventing Segment A from communicating with Segment B, and then define a second policy to prevent Segment B from communicating with Segment A.

1. To define your first blocking policy, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsBlocked** parameter.

SYNTAX	EXAMPLE
`New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segment1name" -SegmentsBlocked "segment2name"`	`New-InformationBarrierPolicy -Name "Sales-Research" -AssignedSegment "Sales" -SegmentsBlocked "Research" -State Inactive` In this example, we defined a policy called *Sales-Research* for a segment called *Sales*. When active and applied, this policy prevents people in *Sales* from communicating with people in a segment called *Research*.

2. To define your second blocking segment, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsBlocked** parameter again, this time with the segments reversed.

EXAMPLE	NOTE
`New-InformationBarrierPolicy -Name "Research-Sales" -AssignedSegment "Research" -SegmentsBlocked "Sales" -State Inactive`	In this example, we defined a policy called *Research-Sales* to prevent *Research* from communicating with *Sales*.

3. Proceed to one of the following actions:

   - (If needed) Define a policy to allow a segment to communicate only with one other segment
   - (After all your policies are defined) Apply information barrier policies

Scenario 2: Allow a segment to communicate only with one other segment

1. To allow one segment to communicate with only one other segment, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsAllowed** parameter.

SYNTAX	EXAMPLE
`New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segment1name" -SegmentsAllowed "segment2name","segment1name"`	`New-InformationBarrierPolicy -Name "Manufacturing-HR" -AssignedSegment "Manufacturing" -SegmentsAllowed "HR","Manufacturing" -State Inactive` In this example, we defined a policy called *Manufacturing-HR* for a segment called *Manufacturing*. When active and applied, this policy allows people in *Manufacturing* to communicate only with people in a segment called *HR*. (In this case, *Manufacturing* cannot communicate with users who are not part of *HR*.)

If needed, you can specify multiple segments with this cmdlet, as shown in the following example.

SYNTAX	EXAMPLE
`New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segment1name" -SegmentsAllowed "segment2name", "segment3name","segment1name"`	`New-InformationBarrierPolicy -Name "Research-HRManufacturing" -AssignedSegment "Research" -SegmentsAllowed "HR","Manufacturing","Research" -State Inactive` In this example, we defined a policy that allows the *Research* segment to communicate with only *HR* and *Manufacturing*.

Repeat this step for each policy you want to define to allow specific segments to communicate with only certain other specific segments.

2. Proceed to one of the following actions:

   - (If needed) Define a policy to block communications between segments
   - (After all your policies are defined) Apply information barrier policies

Part 3: Apply information barrier policies

Information barrier policies are not in effect until you set them to active status, and then apply the policies.

1. Use the **Get-InformationBarrierPolicy** cmdlet to see a list of policies that have been defined. Note the status and identity (GUID) of each policy.

   Syntax: `Get-InformationBarrierPolicy`

2. To set a policy to active status, use the **Set-InformationBarrierPolicy** cmdlet with an **Identity** parameter, and the **State** parameter set to **Active**.

SYNTAX	EXAMPLE
`Set-InformationBarrierPolicy -Identity GUID -State Active`	`Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471 -State Active` In this example, we set an information barrier policy that has the GUID *43c37853-ea10-4b90-a23d-ab8c93772471* to active status.

   Repeat this step as appropriate for each policy.

3. When you have finished setting your information barrier policies to active status, use the **Start-InformationBarrierPoliciesApplication** cmdlet in the Security & Compliance Center.

   Syntax: `Start-InformationBarrierPoliciesApplication`

   After you run `Start-InformationBarrierPoliciesApplication`, allow 30 minutes for the system to start applying the policies. The system applies policies user by user. The system processes about 5,000 user accounts per hour.

View status of user accounts, segments, policies, or policy application

With PowerShell, you can view status of user accounts, segments, policies, and policy application, as listed in the following table.

TO VIEW THIS INFORMATION	TAKE THIS ACTION

TO VIEW THIS INFORMATION	TAKE THIS ACTION

User accounts	Use the **Get-InformationBarrierRecipientStatus** cmdlet with Identity parameters.
	Syntax:
	`Get-InformationBarrierRecipientStatus -Identity <value> -Identity2 <value>`
	You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.
	Example:
	`Get-InformationBarrierRecipientStatus -Identity meganb -Identity2 alexw`
	In this example, we refer to two user accounts in Office 365: *meganb* for *Megan*, and *alexw* for *Alex*.
	(You can also use this cmdlet for a single user:
	`Get-InformationBarrierRecipientStatus -Identity <value>`
	)
	This cmdlet returns information about users, such as attribute values and any information barrier policies that are applied.

Segments	Use the **Get-OrganizationSegment** cmdlet. Syntax: `Get-OrganizationSegment` This cmdlet will display a list of all segments defined for your organization.
Information barrier policies	Use the **Get-InformationBarrierPolicy** cmdlet. Syntax: `Get-InformationBarrierPolicy` This cmdlet will display a list of information barrier policies that were defined, and their status.
The most recent information barrier policy application	Use the **Get-InformationBarrierPoliciesApplicationStatus** cmdlet. Syntax: `Get-InformationBarrierPoliciesApplicationStatus` This cmdlet will display information about whether policy application completed, failed, or is in progress.
All information barrier policy applications	Use `Get-InformationBarrierPoliciesApplicationStatus -All` This cmdlet will display information about whether policy application completed, failed, or is in progress.

What if I need to remove or change policies?

Resources are available to help you manage your information barrier policies.

- If something goes wrong with information barriers, see Troubleshooting information barriers.

- To stop policies from being applied, see Stop a policy application.
- To remove an information barrier policy, see Remove a policy.
- To make changes to segments or policies, see Edit (or remove) information barrier policies.

Example: Contoso's departments, segments, and policies

To see how an organization might approach defining segments and policies, consider the following example.

Contoso's departments and plan

Contoso has five departments: HR, Sales, Marketing, Research, and Manufacturing. In order to remain compliant with industry regulations, people in some departments are not supposed to communicate with other departments, as listed in the following table:

SEGMENT	CAN TALK TO	CANNOT TALK TO
HR	Everyone	(no restrictions)
Sales	HR, Marketing, Manufacturing	Research
Marketing	Everyone	(no restrictions)
Research	HR, Marketing, Manufacturing	Sales
Manufacturing	HR, Marketing	Anyone other than HR or Marketing

For this structure, Contoso's plan includes three information barrier policies:

1. A policy designed to prevent Sales from communicating with Research (and another policy to prevent Research from communicating with Sales).
2. A policy designed to allow Manufacturing to communicate with HR and Marketing only.

For this scenario, it's not necessary to define policies for HR or Marketing.

Contoso's defined segments

Contoso will use the Department attribute in Azure Active Directory to define segments, as follows:

DEPARTMENT	SEGMENT DEFINITION
HR	`New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"`
Sales	`New-OrganizationSegment -Name "Sales" -UserGroupFilter "Department -eq 'Sales'"`
Marketing	`New-OrganizationSegment -Name "Marketing" -UserGroupFilter "Department -eq 'Marketing'"`
Research	`New-OrganizationSegment -Name "Research" -UserGroupFilter "Department -eq 'Research'"`
Manufacturing	`New-OrganizationSegment -Name "Manufacturing" -UserGroupFilter "Department -eq 'Manufacturing'"`

With the segments defined, Contoso proceeds to define policies.

Contoso's information barrier policies

Contoso defines three policies, as described in the following table:

POLICY	POLICY DEFINITION
Policy 1: Prevent Sales from communicating with Research	`New-InformationBarrierPolicy -Name "Sales-Research" -AssignedSegment "Sales" -SegmentsBlocked "Research" -State Inactive` In this example, the information barrier policy is called *Sales-Research*. When this policy is active and applied, it will help prevent users who are in the Sales segment from communicating with users in the Research segment. This policy is a one-way policy; it won't prevent Research from communicating with Sales. For that, Policy 2 is needed.
Policy 2: Prevent Research from communicating with Sales	`New-InformationBarrierPolicy -Name "Research-Sales" -AssignedSegment "Research" -SegmentsBlocked "Sales" -State Inactive` In this example, the information barrier policy is called *Research-Sales*. When this policy is active and applied, it will help prevent users who are in the Research segment from communicating with users in the Sales segment.
Policy 3: Allow Manufacturing to communicate with HR and Marketing only	`New-InformationBarrierPolicy -Name "Manufacturing-HRMarketing" -AssignedSegment "Manufacturing" -SegmentsAllowed "HR","Marketing","Manufacturing" -State Inactive` In this case, the information barrier policy is called *Manufacturing-HRMarketing*. When this policy is active and applied, Manufacturing can communicate only with HR and Marketing. HR and Marketing are not restricted from communicating with other segments.

With segments and policies defined, Contoso applies the policies by running the **Start-InformationBarrierPoliciesApplication** cmdlet.

When the cmdlet finishes, Contoso is compliant with legal and industry requirements.

Attributes for information barrier policies

2/18/2021 • 2 minutes to read • Edit Online

Certain attributes in Azure Active Directory can be used to segment users. Once segments are defined, those segments can be used as filters for information barrier policies. For example, you might use **Department** to define segments of users by department within your organization (assuming no single employee works for two departments at the same time).

This article describes how to use attributes with information barriers, and it provides a list of attributes that can be used. To learn more about information barriers, see the following resources:

- Information barriers
- Define policies for information barriers in Microsoft Teams
- Edit (or remove) information barrier policies

How to use attributes in information barrier policies

The attributes listed in this article can be used to define or edit segments of users. Your defined segments serve as parameters (called *UserGroupFilter* values) in information barrier policies.

1. Determine which attribute you want to use to define segments. (See the Reference section in this article.)
2. Make sure the user accounts have values filled in for the attribute(s) you selected in Step 1. View user account details, and if necessary, edit user accounts to include attribute values.
   - To edit multiple accounts (or use PowerShell to edit a single account), see Configure user account properties with Office 365 PowerShell.
   - To edit a single account, see Add or update a user's profile information using Azure Active Directory.
3. Define segments using PowerShell, similar to the following examples:

EXAMPLE	CMDLET
Define a segment called Segment1 using the Department attribute	`New-OrganizationSegment -Name "Segment1" -UserGroupFilter "Department -eq 'Department1'"`
Define a segment called SegmentA using the MemberOf attribute (suppose this attribute contains group names, such as "BlueGroup")	`New-OrganizationSegment -Name "SegmentA" -UserGroupFilter "MemberOf -eq 'BlueGroup'"`
Define a segment called DayTraders using ExtensionAttribute1 (suppose this attribute contains job titles, such as "DayTrader")	`New-OrganizationSegment -Name "DayTraders" -UserGroupFilter "ExtensionAttribute1 -eq 'DayTrader'"`

TIP

When you define segments, use the same attribute for all your segments. For example, if you define some segments using *Department*, define all of the segments using *Department*. Don't define some segments using *Department* and others using *MemberOf*. Make sure your segments do not overlap; each user should be assigned to exactly one segment.

Reference

The following table lists the attributes that you can use with information barriers.

AZURE ACTIVE DIRECTORY PROPERTY NAME (LDAP DISPLAY NAME)	EXCHANGE PROPERTY NAME
Co	Co
Company	Company
Department	Department
ExtensionAttribute1	CustomAttribute1
ExtensionAttribute2	CustomAttribute2
ExtensionAttribute3	CustomAttribute3
ExtensionAttribute4	CustomAttribute4
ExtensionAttribute5	CustomAttribute5
ExtensionAttribute6	CustomAttribute6
ExtensionAttribute7	CustomAttribute7
ExtensionAttribute8	CustomAttribute8

Troubleshooting information barriers

2/18/2021 • 9 minutes to read • Edit Online

Information barriers can help your organization remain compliant with legal requirements and industry regulations. For example, with information barriers, you can restrict communication between specific groups of users to avoid a conflict of interest or other issues. (To learn more about how to set up information barriers, see Define policies for information barriers.)

In the event that people run into unexpected issues after information barriers are in place, there are some steps you can take to resolve those issues. Use this article as a guide.

> **IMPORTANT**
>
> To perform the tasks described in this article, you must be assigned an appropriate role, such as one of the following:
> - Microsoft 365 Enterprise Global Administrator
> - global administrator
> - Compliance Administrator
> - IB Compliance Management (this is a new role!)
>
> To learn more about prerequisites for information barriers, see Prerequisites (for information barrier policies).
>
> Make sure to connect to Security & Compliance Center PowerShell.

Issue: Users are unexpectedly blocked from communicating with others in Microsoft Teams

In this case, people are reporting unexpected issues communicating with others in Microsoft Teams. Some examples are:

- A user searches for, but is unable to find, another user in Microsoft Teams.
- A user can find, but cannot select, another user in Microsoft Teams.
- A user can see another user, but cannot send messages to that other user in Microsoft Teams.

What to do

Determine whether the users are affected by an information barrier policy. Depending on how policies are configured, information barriers might be working as expected. Or, you might have to refine your organization's policies.

1. Use the **Get-InformationBarrierRecipientStatus** cmdlet with the Identity parameter.

SYNTAX	EXAMPLE
`Get-InformationBarrierRecipientStatus -Identity` You can use any identity value that uniquely identifies each recipient, such as Name, Alias, Distinguished name (DN), Canonical DN, Email address, or GUID.	`Get-InformationBarrierRecipientStatus -Identity meganb` In this example, we are using an alias (*meganb*) for the Identity parameter. This cmdlet will return information that indicates whether the user is affected by an information barrier policy. (Look for *ExoPolicyId: <GUID>.)

   If the users are not included in information barrier policies, contact support. Otherwise, proceed to the next step.

2. Find out which segments are included in an information barrier policy. To do this, use the `Get-InformationBarrierPolicy` cmdlet with the Identity parameter.

SYNTAX	EXAMPLE
`Get-InformationBarrierPolicy` Use details, such as the policy GUID (ExoPolicyId) you received during the previous step, as an identity value.	`Get-InformationBarrierPolicy -Identity b42c3d0f-49e9-4506-a0a5-bf2853b5df6f` In this example, we are getting detailed information about the information barrier policy that has ExoPolicyId *b42c3d0f-49e9-4506-a0a5-bf2853b5df6f*.

   After you run the cmdlet, in the results, look for **AssignedSegment**, **SegmentsAllowed**, and **SegmentsBlocked** values.

   For example, after running the `Get-InformationBarrierPolicy` cmdlet, we saw the following in our list of results:

```
AssignedSegment : Sales
SegmentsAllowed : {}
SegmentsBlocked : {Research}
```

   In this case, we can see that an information barrier policy affects people who are in the Sales and Research segments. In this case, people in Sales are prevented from communicating with people in Research.

   If this seems correct, then information barriers are working as expected. If not, proceed to the next step.

3. Make sure your segments are defined correctly. To do this, use the `Get-OrganizationSegment` cmdlet, and review the list of results.

SYNTAX	EXAMPLE
`Get-OrganizationSegment` Use this cmdlet with an Identity parameter.	`Get-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd` In this example, we are getting information about the segment that has GUID *c96e0837-c232-4a8a-841e-ef45787d8fcd*.

   Review the details for the segment. If necessary, edit a segment, and then re-use the `Start-InformationBarrierPoliciesApplication` cmdlet.

   If you are still having issues with your information barrier policy, contact support.

Issue: Communications are allowed between users who should be blocked in Microsoft Teams

In this case, although information barriers are defined, active, and applied, people who should be prevented from communicating with each other are somehow able to chat with and call each other in Microsoft Teams.

What to do

Verify that the users in question are included in an information barrier policy.

1. Use the **Get-InformationBarrierRecipientStatus** cmdlet with Identity parameters.

SYNTAX*	EXAMPLE
`Get-InformationBarrierRecipientStatus -Identity <value> -Identity2 <value>` You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.	`Get-InformationBarrierRecipientStatus -Identity meganb -Identity2 alexw` In this example, we refer to two user accounts in Office 365: *meganb* for *Megan*, and *alexw* for *Alex*.

> **TIP**
> You can also use this cmdlet for a single user: `Get-InformationBarrierRecipientStatus -Identity <value>`

2. Review the findings. The **Get-InformationBarrierRecipientStatus** cmdlet returns information about users, such as attribute values and any information barrier policies that are applied.

   Review the results, and then take your next steps, as described in the following table:

RESULTS	WHAT TO DO NEXT
No segments are listed for the selected user(s)	Do one of the following: - Assign users to an existing segment by editing their user profiles in Azure Active Directory. (See Configure user account properties with Office 365 PowerShell.) - Define a segment using a supported attribute for information barriers. Then, either define a new policy or edit an existing policy to include that segment.
Segments are listed but no information barrier policies are assigned to those segments	Do one of the following: - Define a new information barrier policy for each segment in question - Edit an existing information barrier policy to assign it to the correct segment
Segments are listed and each is included in an information barrier policy	- Run the `Get-InformationBarrierPolicy` cmdlet to verify that information barrier policies are active - Run the `Get-InformationBarrierPoliciesApplicationStatus` cmdlet to confirm the policies are applied - Run the `Start-InformationBarrierPoliciesApplication` cmdlet to apply all active information barrier policies

Issue: I need to remove a single user from an information barrier policy

In this case, information barrier policies are in effect, and a one or more users are unexpectedly blocked from communicating with others in Microsoft Teams. Rather than remove information barrier policies altogether, you can remove one or more individual users from information barrier policies.

What to do

Information barrier policies are assigned to segments of users. Segments are defined by using certain attributes in user account profiles. If you must remove a policy from a single user, consider editing that user's profile in Azure Active Directory such that the user is no longer included in a segment affected by information barriers.

1. Use the **Get-InformationBarrierRecipientStatus** cmdlet with Identity parameters. This cmdlet returns

information about users, such as attribute values and any information barrier policies that are applied.

SYNTAX	EXAMPLE
`Get-InformationBarrierRecipientStatus -Identity <value> -Identity2 <value>` You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.	`Get-InformationBarrierRecipientStatus -Identity meganb -Identity2 alexw` In this example, we refer to two user accounts in Office 365: *meganb* for *Megan*, and *alexw* for *Alex*.
`Get-InformationBarrierRecipientStatus -Identity <value>` You can use any value that uniquely identifies the user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.	`Get-InformationBarrierRecipientStatus -Identity jeanp` In this example, we refer to a single account in Office 365: *jeanp*.

2. Review the results to see if information barrier policies are assigned, and to which segment(s) the user(s) belong.
3. To remove a user from a segment affected by information barriers, update the user's profile information in Azure Active Directory.
4. Wait about 30 minutes for FwdSync to occur. Or, run the `Start-InformationBarrierPoliciesApplication` cmdlet to apply all active information barrier policies.

Issue: The information barrier application process is taking too long

After running the **Start-InformationBarrierPoliciesApplication** cmdlet, the process is taking a really long time to finish.

What to do

Keep in mind that when you run the policy application cmdlet, information barrier policies are being applied (or removed), user by user, for all accounts in your organization. If you have a lot of users, it will take a while to process. (As a general guideline, it takes about an hour to process 5,000 user accounts.)

1. Use the **Get-InformationBarrierPoliciesApplicationStatus** cmdlet to verify status of the most recent policy application.

TO VIEW THE MOST RECENT POLICY APPLICATION	TO VIEW STATUS FOR ALL POLICY APPLICATIONS
`Get-InformationBarrierPoliciesApplicationStatus`	`Get-InformationBarrierPoliciesApplicationStatus -All $true`

   This will display information about whether policy application completed, failed, or is in progress.

2. Depending on the results of the previous step, take one of the following steps:

STATUS	NEXT STEP
Not started	If it has been more than 45 minutes since the **Start-InformationBarrierPoliciesApplication** cmdlet has been run, review your audit log to see if there are any errors in policy definitions, or some other reason why the application has not started.

STATUS	NEXT STEP
Failed	If the application has failed, review your audit log. Also review your segments and policies. Are any users assigned to more than one segment? Are any segments assigned more than one poliicy? If necessary, edit segments and/or edit policies, and then run the **Start-InformationBarrierPoliciesApplication** cmdlet again.
In progress	If the application is still in progress, allow more time for it to complete. If it has been several days, gather your audit logs, and then contact support.

Issue: Information barrier policies are not being applied at all

In this case, you have defined segments, defined information barrier policies, and have attempted to apply those policies. However, when you run the `Get-InformationBarrierPoliciesApplicationStatus` cmdlet, you can see that policy application has failed.

What to do

Make sure that your organization does not have Exchange address book policies in place. Such policies will prevent information barrier policies from being applied.

1. Connect to Exchange Online PowerShell.
2. Run the Get-AddressBookPolicy cmdlet, and review the results.

RESULTS	NEXT STEP
Exchange address book policies are listed	Remove address book policies
No address book policies exist	Review your audit logs to find out why policy application is failing

3. View status of user accounts, segments, policies, or policy application.

Issue: Information barrier policy not applied to all designated users

After you have defined segments, defined information barrier policies, and have attempted to apply those policies, you may find that the policy is applying to some recipients, but not to others. When you run the `Get-InformationBarrierPoliciesApplicationStatus` cmdlet, search the output for text like this.

> Identity: `<application guid>`
>
> Total Recipients: 81527
>
> Failed Recipients: 2
>
> Failure Category: None
>
> Status: Complete

What to do

1. Search in the audit log for `<application guid>`. You can copy this PowerShell code and modify for your variables.

```
$DetailedLogs = Search-UnifiedAuditLog -EndDate <yyyy-mm-ddThh:mm:ss>  -StartDate <yyyy-mm-ddThh:mm:ss> -
RecordType InformationBarrierPolicyApplication -ResultSize 1000 |?{$_.AuditData.Contains(<application
guid>)}
```

2. Check the detailed output from the audit log for the values of the `"UserId"` and `"ErrorDetails"` fields. This will give you the reason for the failure. You can copy this PowerShell code and modify for your variables.

```
   $DetailedLogs[1] |fl
```

For example:

> "UserId": User1
>
> "ErrorDetails":"Status: IBPolicyConflict. Error: IB segment "segment id1" and IB segment "segment id2" has conflict and cannot be assigned to the recipient.

3. Usually, you will find that a user has been included in more than one segment. You can fix this by updating the `-UserGroupFilter` value in `OrganizationSegments`.
4. Re-apply information barrier policies using these procedures Information Barriers policies.

Manage information barrier policies

2/18/2021 • 6 minutes to read • Edit Online

After you have defined information barrier policies, you might need to make changes to those policies or to your user segments, as part of troubleshooting or as regular maintenance. Use this article as a guide.

What do you want to do?

ACTION	DESCRIPTION
Edit user account attributes	Fill in attributes in Azure Active Directory that can be used to define segments. Edit user account attributes when users are not included in segments they should be, to change which segments users are in, or to define segments using different attributes.
Edit a segment	Edit segments when you want to change how a segment is defined. For example, you might have originally defined segments using *Department* and now want to use another attribute, such as *MemberOf*.
Edit a policy	Edit an information barrier policy when you want to change how a policy works. For example, instead of blocking communications between two segments, you might decide you want to allow communications to occur only between certain segments.
Set a policy to inactive status	Set a policy to inactive status when you want to make changes to a policy, or when you don't want a policy to be in effect.
Remove a policy	Remove an information barrier policy when you no longer need a particular policy in place.
Stop a policy application	Take this action when you want to stop the process of applying information barrier policies. Stopping a policy application is not instant, and it does not undo policies that are already applied to users.
Define policies for information barriers	Define an information barrier policy when you do not already have such policies in place, and you must restrict or limit communications between specific groups of users.
Troubleshooting information barriers	Refer to this article when you run into unexpected issues with information barriers.

IMPORTANT

To perform the tasks described in this article, you must be assigned an appropriate role, such as one of the following:
- Microsoft 365 Enterprise Global Administrator
- Global Administrator
- Compliance Administrator
- IB Compliance Management (this is a new role!)

To learn more about prerequisites for information barriers, see Prerequisites (for information barrier policies).

Make sure to connect to the Security & Compliance Center PowerShell.

Edit user account attributes

Use this procedure to edit attributes that are used for segmenting users. For example, if you are using a Department attribute, and one or more user accounts do not currently have any values listed for Department, you must edit those user accounts to include Department information. User account attributes are used for defining segments so that information barrier policies can be assigned.

1. To view details for a specific user account, such as attribute values and assigned segment(s), use the **Get-InformationBarrierRecipientStatus** cmdlet with Identity parameters.

SYNTAX	EXAMPLE
`Get-InformationBarrierRecipientStatus -Identity <value> -Identity2 <value>` You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID. (You can also use this cmdlet for a single user: `Get-InformationBarrierRecipientStatus -Identity <value>`)	`Get-InformationBarrierRecipientStatus -Identity meganb -Identity2 alexw` In this example, we refer to two user accounts in Office 365: *meganb* for *Megan*, and *alexw* for *Alex*.

2. Determine which attribute you want to edit for your user account profile(s). For more information, see Attributes for information barrier policies.

3. Edit one or more user accounts to include values for the attribute you selected in the previous step. To take this action, use one of the following procedures:

   - To edit a single account, see Add or update a user's profile information using Azure Active Directory.
   - To edit multiple accounts (or use PowerShell to edit a single account), see Configure user account properties with Office 365 PowerShell.

Edit a segment

Use this procedure edit the definition of a user segment. For example, you might change the name of a segment, or the filter that is used to determine who's included in the segment.

1. To view all existing segments, use the **Get-OrganizationSegment** cmdlet.

   Syntax: `Get-OrganizationSegment`

   You will see a list of segments and details for each, such as segment type, its UserGroupFilter value, who

created or last modified it, GUID, and so on.

> **TIP**
> Print or save your list of segments for reference later. For example, if you want to edit a segment, you will need to know its name or identify value (this is used with the Identity parameter).

2. To edit a segment, use the **Set-OrganizationSegment** cmdlet with the **Identity** parameter and relevant details.

SYNTAX	EXAMPLE
`Set-OrganizationSegment -Identity GUID -UserGroupFilter "attribute -eq 'attributevalue'"`	`Set-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd -UserGroupFilter "Department -eq 'HRDept'"` In this example, for the segment that has the GUID *c96e0837-c232-4a8a-841e-ef45787d8fcd*, we updated the department name to "HRDept".

When you have finished editing segments for your organization, you can either define or edit information barrier policies.

Edit a policy

1. To view a list of current information barrier policies, use the **Get-InformationBarrierPolicy** cmdlet.

   Syntax: `Get-InformationBarrierPolicy`

   In the list of results, identify the policy that you want to change. Note the policy's GUID and name.

2. Use the **Set-InformationBarrierPolicy** cmdlet with an **Identity** parameter, and specify the changes you want to make.

   Example: Suppose a policy was defined to block the *Research* segment from communicating with the *Sales* and *Marketing* segments. The policy was defined by using this cmdlet:

   ```
   New-InformationBarrierPolicy -Name "Research-SalesMarketing" -AssignedSegment "Research" -SegmentsBlocked "Sales","Marketing"
   ```

   Suppose we want to change it so that people in the *Research* segment can only communicate with people in the *HR* segment. To make this change, we use this cmdlet:

   ```
   Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471 -SegmentsAllowed "HR"
   ```

   In this example, we changed "SegmentsBlocked" to "SegmentsAllowed" and specified the *HR* segment.

3. When you are finished editing a policy, make sure to apply your changes. (See Apply information barrier policies.)

Set a policy to inactive status

1. To view a list of current information barrier policies, use the **Get-InformationBarrierPolicy** cmdlet.

   Syntax: `Get-InformationBarrierPolicy`

   In the list of results, identify the policy that you want to change (or remove). Note the policy's GUID and name.

2. To set the policy's status to inactive, use the **Set-InformationBarrierPolicy** cmdlet with an Identity parameter and the State parameter set to Inactive.

SYNTAX	EXAMPLE
`Set-InformationBarrierPolicy -Identity GUID -State Inactive`	`Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c9377247 -State Inactive` In this example, we set an information barrier policy that has GUID *43c37853-ea10-4b90-a23d-ab8c9377247* to an inactive status.

3. To apply your changes, use the **Start-InformationBarrierPoliciesApplication** cmdlet.

   Syntax: `Start-InformationBarrierPoliciesApplication`

   Changes are applied, user by user, for your organization. If your organization is large, it can take 24 hours (or more) for this process to complete. (As a general guideline, it takes about an hour to process 5,000 user accounts.)

At this point, one or more information barrier policies are set to inactive status. From here, you can do any of the following actions:

- Keep it as is (a policy set to inactive status has no effect on users)
- Edit a policy
- Remove a policy

Remove a policy

1. To view a list of current information barrier policies, use the **Get-InformationBarrierPolicy** cmdlet.

   Syntax: `Get-InformationBarrierPolicy`

   In the list of results, identify the policy that you want to remove. Note the policy's GUID and name. Make sure the policy is set to inactive status.

2. Use the **Remove-InformationBarrierPolicy** cmdlet with an Identity parameter.

SYNTAX	EXAMPLE
`Remove-InformationBarrierPolicy -Identity GUID`	`Remove-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471` In this example, we are removing the policy that has GUID *43c37853-ea10-4b90-a23d-ab8c93772471*.

   When prompted, confirm the change.

3. Repeat steps 1-2 for each policy you want to remove.

4. When you are finished removing policies, apply your changes. To take this action, use the **Start-InformationBarrierPoliciesApplication** cmdlet.

   Syntax: `Start-InformationBarrierPoliciesApplication`

   Changes are applied, user by user, for your organization. If your organization is large, it can take 24 hours (or more) for this process to complete.

Stop a policy application

After you have started applying information barrier policies, if you want to stop those policies from being applied, use the following procedure. It will take approximately 30-35 minutes for the process to begin.

1. To view the status of the most recent information barrier policy application, use the **Get-InformationBarrierPoliciesApplicationStatus** cmdlet.

   Syntax: `Get-InformationBarrierPoliciesApplicationStatus`

   Note the application's GUID.

2. Use the **Stop-InformationBarrierPoliciesApplication** cmdlet with an Identity parameter.

SYNTAX	EXAMPLE
`Stop-InformationBarrierPoliciesApplication -Identity GUID`	`Stop-InformationBarrierPoliciesApplication -Identity 46237888-12ca-42e3-a541-3fcb7b5231d1` In this example, we are stopping information barrier policies from being applied.

Privileged access management in Microsoft 365

2/18/2021 • 2 minutes to read • Edit Online

Having standing access by some users to sensitive information or critical network configuration settings in Microsoft Exchange Online is a potential pathway for compromised accounts or internal threat activities. Privileged access management helps protect your organization from breaches and helps to meet compliance best practices by limiting standing access to sensitive data or access to critical configuration settings. Instead of administrators having constant access, just-in-time access rules are implemented for tasks that need elevated permissions. Enabling privileged access management for Exchange Online in Microsoft 365 allows your organization to operate with zero standing privileges and provide a layer of defense against standing administrative access vulnerabilities.

Configure privileged access management for Microsoft 365

Use the following steps to configure privileged access management for your organization:

1. Learn about privileged access management in Microsoft 365
2. Create an approver's group
3. Enable privileged access management
4. Create an access policy
5. Submit/approve privileged access requests

More information about privileged access management

Learn about privileged access management

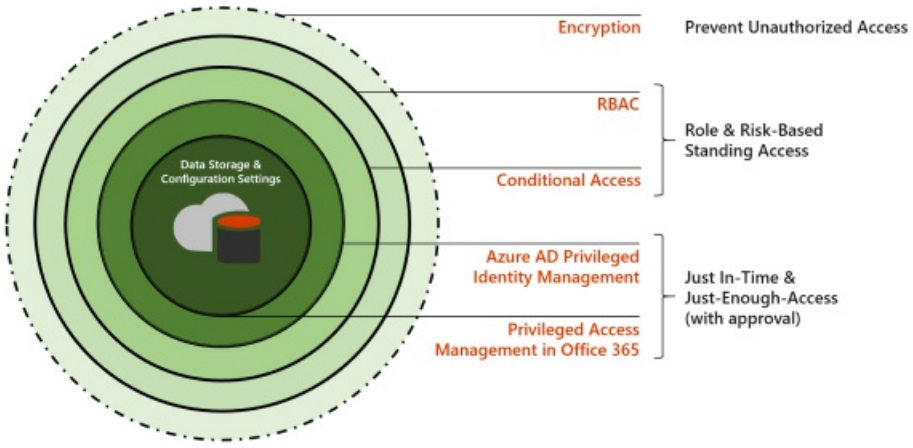
2/18/2021 • 4 minutes to read • Edit Online

Privileged access management allows granular access control over privileged admin tasks in Office 365. It can help protect your organization from breaches that use existing privileged admin accounts with standing access to sensitive data or access to critical configuration settings. Privileged access management requires users to request just-in-time access to complete elevated and privileged tasks through a highly scoped and time-bounded approval workflow. This configuration gives users just-enough-access to perform the task at hand, without risking exposure of sensitive data or critical configuration settings. Enabling privileged access management in Microsoft 365 allows your organization to operate with zero standing privileges and provide a layer of defense against standing administrative access vulnerabilities.

For a quick overview of the integrated Customer Lockbox and privileged access management workflow, see this Customer Lockbox and privileged access management video.

Layers of protection

Privileged access management complements other data and access feature protections within the Microsoft 365 security architecture. Including privileged access management as part of an integrated and layered approach to security provides a security model that maximizes protection of sensitive information and Microsoft 365 configuration settings. As shown in the diagram, privileged access management builds on the protection provided with native encryption of Microsoft 365 data and the role-based access control security model of Microsoft 365 services. When used with Azure AD Privileged Identity Management, these two features provide access control with just-in-time access at different scopes.



Privileged access management is defined and scoped at the **task** level, while Azure AD Privileged Identity Management applies protection at the **role** level with the ability to execute multiple tasks. Azure AD Privileged Identity Management primarily allows managing accesses for AD roles and role groups, while privileged access management in Microsoft 365 applies only at the task level.

- **Enabling privileged access management while already using Azure AD Privileged Identity Management:** Adding privileged access management provides another granular layer of protection and audit capabilities for privileged access to Microsoft 365 data.
- **Enabling Azure AD Privileged Identity Management while already using privileged access management in Office 365:** Adding Azure AD Privileged Identity Management to privileged access management can extend privileged access to data outside of Microsoft 365 that's primarily defined by

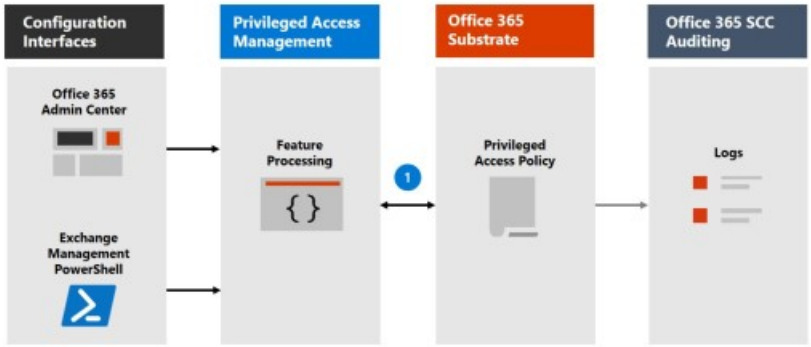
user roles or identity.

Privileged access management architecture and process flow

Each of the following process flows outline the architecture of privileged access and how it interacts with the Microsoft 365 substrate, auditing, and the Exchange Management runspace.

Step 1: Configure a privileged access policy

When you configure a privileged access policy with the Microsoft 365 admin center or the Exchange Management PowerShell, you define the policy and the privileged access feature processes and the policy attributes in the Microsoft 365 substrate. The activities are logged in the Security & Compliance Center. The policy is now enabled and ready to handle incoming requests for approvals.

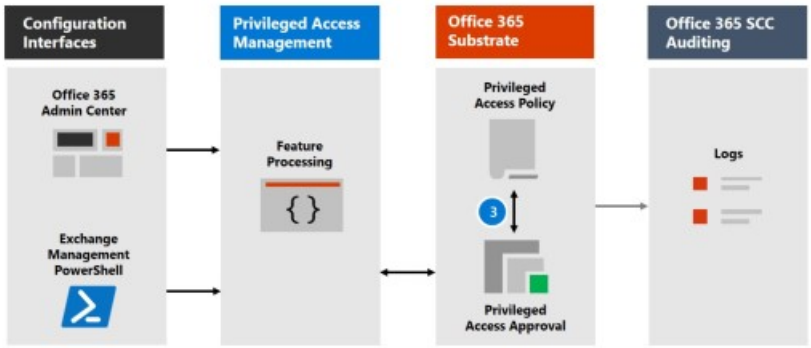


Step 2: Access request

In the Microsoft 365 admin center or with the Exchange Management PowerShell, users can request access to elevated or privileged tasks. The privileged access feature sends the request to the Microsoft 365 substrate for processing against the configured privilege access policy and records the Activity in the Security & Compliance Center logs.

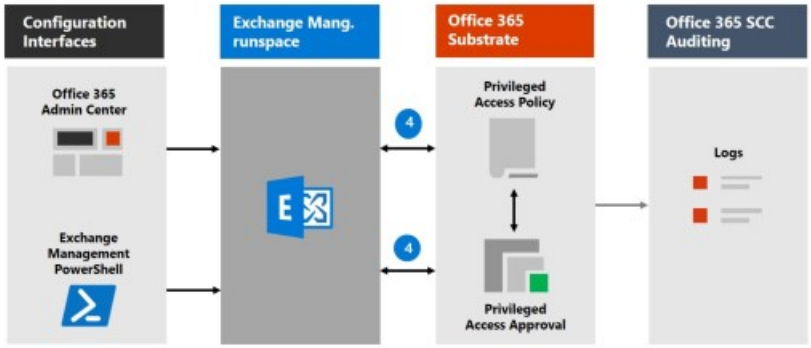
Step 3: Access approval

An approval request is generated and the pending request notification is emailed to approvers. If approved, the privileged access request is processed as an approval and the task is ready to be completed. If denied, the task is blocked and no access is granted to the requestor. The requestor is notified of the request approval or denial via email message.



Step 4: Access processing

For an approved request, the task is processed by the Exchange Management runspace. The approval is checked against the privileged access policy and processed by the Microsoft 365 substrate. All activity for the task is logged in the Security & Compliance Center.



Frequently asked questions

What SKUs can use privileged access in Office 365?

Privileged access management is available for customers for a wide selection of Microsoft 365 and Office 365 subscriptions and add-ons. See Get started with privileged access management for details.

When will privileged access support Office 365 workloads beyond Exchange?

Privileged access management will be available in other Office 365 workloads soon. Visit the Microsoft 365 Roadmap for more details.

My organization needs more than 30 privileged access policies, will this limit be increased?

Yes, raising the current limit of 30 privileged access policies per organization is on the feature roadmap.

Do I need to be a Global Admin to manage privileged access in Office 365?

No, you need the Exchange Role Management role assigned to accounts that manage privileged access in Office 365. If you don't want to configure the Role Management role as a stand-alone account permission, the Global Administrator role includes this role by default and can manage privileged access. Users included in an approvers' group don't need to be a Global Admin or have the Role Management role assigned to review and approve requests with PowerShell.

How is privileged access management related to Customer Lockbox?

Customer Lockbox allows a level of access control for organizations when Microsoft accesses data. Privileged access management allows granular access control within an organization for all Microsoft 365 privileged tasks.

Ready to get started?

Start configuring your organization for privileged access management.

Learn more

Interactive guide: Monitor and control administrator tasks with privileged access management

Get started with privileged access management

2/18/2021 • 8 minutes to read • Edit Online

This topic guides you through enabling and configuring privileged access management in your organization. You can use either the Microsoft 365 admin center or Exchange Management PowerShell to manage and use privileged access.

Before you begin

Before you get started with privileged access management, you should confirm your Microsoft 365 subscription and any add-ons. To access and use privileged access management, your organization must have one of the following subscriptions or add-ons:

- Microsoft 365 E5 subscription (paid or trial version)
- Microsoft 365 E3 subscription (or Office 365 E3 subscription + Enterprise Mobility and Security E3 subscription) + the Microsoft 365 E5 Compliance add-on
- Any Microsoft 365, Office 365, Exchange, SharePoint, or OneDrive for Business subscription + the Microsoft 365 E5 Insider Risk Management add-on
- Microsoft 365 A5 subscription (paid or trial version)
- Microsoft 365 A3 subscription (or Office 365 A3 subscription + Enterprise Mobility and Security A3 subscription) + the Microsoft A5 Compliance add-on
- Any Microsoft 365, Office 365, Exchange, SharePoint, or OneDrive for Education subscription + the Microsoft 365 A5 Insider Risk Management add-on
- Office 365 Enterprise E5 subscription (paid or trial version)
- Office 365 Enterprise E3 subscription + the Office 365 Advanced Compliance add-on (no longer available for new subscriptions, see note)

Users submitting and responding to privileged access management requests must be assigned one of the licenses above.

> **IMPORTANT**
> Office 365 Advanced Compliance is no longer sold as a standalone subscription. When current subscriptions expire, customers should transition to one of the subscriptions above, which contain the same or additional compliance features.

If you don't have an existing Office 365 Enterprise E5 plan and want to try privileged access management, you can add Microsoft 365 to your existing Office 365 subscription or sign up for a trial of Microsoft 365 Enterprise E5.

Enable and configure privileged access management

Follow these steps to set up and use privileged access in your organization:

- Step 1: Create an approver's group

  Before you start using privilege access, determine who needs approval authority for incoming requests for access to elevated and privileged tasks. Any user who is part of the Approvers' group is able to approve access requests. This group is enabled by creating a mail-enabled security group in Office 365.

- Step 2: Enable privileged access

Privileged access must be explicitly enabled in Office 365 with the default approver group, including a set of system accounts that you want excluded from the privileged access management access control.

- Step 3: Create an access policy

  Creating an approval policy allows you to define the specific approval requirements scoped at individual tasks. The approval type options are **Auto** or **Manual**.

- Step 4: Submit/approve privileged access requests

  Once enabled, privileged access requires approvals for any task that has an associated approval policy defined. For tasks included in an approval policy, users must request and be granted access approval to have permissions necessary to execute the task.

After approval is granted, the requesting user can execute the intended task and privileged access will authorize and execute the task on behalf of the user. The approval remains valid for the requested duration (default duration is 4 hours), during which the requester can execute the intended task multiple times. All such executions are logged and made available for security and compliance auditing.

> **NOTE**
> If you want to use Exchange Management PowerShell to enable and configure privileged access, follow the steps in Connect to Exchange Online PowerShell using Multi-Factor authentication to connect to Exchange Online PowerShell with your Office 365 credentials. You do not need to enable multi-factor authentication for your organization to use the steps to enable privileged access while connecting to Exchange Online PowerShell. Connecting with multi-factor authentication creates an OAuth token that is used by privileged access for signing your requests.

Step 1: Create an approver's group

1. Sign into the Microsoft 365 admin center using credentials for an admin account in your organization.
2. In the Admin Center, go to **Groups** > **Add a group**.
3. Select **mail-enabled security group** and then complete the **Name**, **Group email address**, and **Description** fields for the new group.
4. Save the group. It may take a few minutes for the group to be fully configured and to appear in the Microsoft 365 admin center.
5. Select the new approver's group and select **edit** to add users to the group.
6. Save the group.

Step 2: Enable privileged access

In the Microsoft 365 Admin Center

1. Sign into the Microsoft 365 Admin Center using credentials for an admin account in your organization.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Enable the **Require approvals for privileged tasks** control.
4. Assign the approver's group you created in Step 1 as the **Default approvers group**.
5. **Save** and **Close**.

In Exchange Management PowerShell

To enable privileged access and to assign the approver's group, run the following command in Exchange Online

PowerShell:

```
Enable-ElevatedAccessControl -AdminGroup '<default approver group>' -SystemAccounts
@('<systemAccountUPN1>','<systemAccountUPN2>')
```

Example:

```
Enable-ElevatedAccessControl -AdminGroup 'pamapprovers@fabrikam.onmicrosoft.com' -SystemAccounts
@('sys1@fabrikamorg.onmicrosoft.com', 'sys2@fabrikamorg.onmicrosoft.com')
```

NOTE

System accounts feature is made available to ensure certain automations within your organizations can work without dependency on privileged access, however it is recommended that such exclusions be exceptional and those allowed should be approved and audited regularly.

Step 3: Create an access policy

You can create and configure up to 30 privileged access policies for your organization.

In the Microsoft 365 Admin Center

1. Sign into the Microsoft 365 Admin Center using credentials for an admin account in your organization.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **Configure policies** and select **Add a policy**.
5. From the drop-down fields, select the appropriate values for your organization:

   Policy type: Task, Role, or Role Group

   Policy scope: Exchange

   Policy name: Select from the available policies

   Approval type: Manual or Auto

   Approval group: Select the approvers group created in Step 1
6. Select **Create** and then **Close**. It may take a few minutes for the policy to be fully configured and enabled.

In Exchange Management PowerShell

To create and define an approval policy, run the following command in Exchange Online PowerShell:

```
New-ElevatedAccessApprovalPolicy -Task 'Exchange\<exchange management cmdlet name>' -ApprovalType <Manual,
Auto> -ApproverGroup '<default/custom approver group>'
```

Example:

```
New-ElevatedAccessApprovalPolicy -Task 'Exchange\New-MoveRequest' -ApprovalType Manual -ApproverGroup
'mbmanagers@fabrikamorg.onmicrosoft.com'
```

Step 4: Submit/approve privileged access requests

Requesting elevation authorization to execute privileged tasks

Requests for privileged access are valid for up to 24 hours after the request is submitted. If not approved or denied, the requests expire and access is not approved.

In the Microsoft 365 Admin Center

1. Sign into the Microsoft 365 Admin Center using your credentials.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **New request**. From the drop-down fields, select the appropriate values for your organization:

   Request type: Task, Role, or Role Group

   Request scope: Exchange

   Request for: Select from the available policies

   Duration (hours): Number of hours of requested access. There isn't a limit on the number of hours that can be requested.

   Comments: Text field for comments related to your access request
5. Select **Save** and then **Close**. Your request will be sent to the approver's group via email.

In Exchange Management PowerShell

Run the following command in Exchange Online PowerShell to create and submit an approval request to the approver's group:

```
New-ElevatedAccessRequest -Task 'Exchange\<exchange management cmdlet name>' -Reason '<appropriate reason>'
-DurationHours <duration in hours>
```

Example:

```
New-ElevatedAccessRequest -Task 'Exchange\New-MoveRequest' -Reason 'Attempting to fix the user mailbox
error' -DurationHours 4
```

View status of elevation requests

After an approval request is created, elevation request status can be reviewed in the admin center or in Exchange Management PowerShell using the associated with request ID.

In the Microsoft 365 admin center

1. Sign into the Microsoft 365 admin center with your credentials.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **View** to filter submitted requests by **Pending**, **Approved**, **Denied**, or **Customer Lockbox** status.

In Exchange Management PowerShell

Run the following command in Exchange Online PowerShell to view an approval request status for a specific request ID:

```
Get-ElevatedAccessRequest -Identity <request ID> | select RequestStatus
```

Example:

```
Get-ElevatedAccessRequest -Identity 28560ed0-419d-4cc3-8f5b-603911cbd450 | select RequestStatus
```

Approving an elevation authorization request

When an approval request is created, members of the relevant approver group receive an email notification and can approve the request associated with the request ID. The requestor is notified of the request approval or denial via email message.

In the Microsoft 365 admin center

1. Sign into the Microsoft 365 admin center with your credentials.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select a listed request to view the details and to take action on the request.
5. Select **Approve** to approve the request or select **Deny** to deny the request. Previously approved requests can have access revoked by selecting **Revoke**.

In Exchange Management PowerShell

To approve an elevation authorization request, run the following command in Exchange Online PowerShell:

```
Approve-ElevatedAccessRequest -RequestId <request id> -Comment '<approval comment>'
```

Example:

```
Approve-ElevatedAccessRequest -RequestId a4bc1bdf-00a1-42b4-be65-b6c63d6be279 -Comment '<approval comment>'
```

To deny an elevation authorization request, run the following command in Exchange Online PowerShell:

```
Deny-ElevatedAccessRequest -RequestId <request id> -Comment '<denial comment>'
```

Example:

```
Deny-ElevatedAccessRequest -RequestId a4bc1bdf-00a1-42b4-be65-b6c63d6be279 -Comment '<denial comment>'
```

Delete a privileged access policy in Office 365

If it is no longer needed in your organization, you can delete a privileged access policy.

In the Microsoft 365 admin center

1. Sign into the Microsoft 365 admin center using credentials for an admin account in your organization.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **Configure policies**.
5. Select the policy you want to delete, then select **Remove Policy**.
6. Select **Close**.

In Exchange Management PowerShell

To delete a privileged access policy, run the following command in Exchange Online Powershell:

```
Remove-ElevatedAccessApprovalPolicy -Identity <identity GUID of the policy you want to delete>
```

Disable privileged access in Office 365

If needed, you can disable privileged access management for your organization. Disabling privileged access does not delete any associated approval policies or approver groups.

In the Microsoft 365 admin center

1. Sign into the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Enable the **Require approvals for privileged access** control.

In Exchange Management PowerShell

To disable privileged access, run the following command in Exchange Online Powershell:

```
Disable-ElevatedAccessControl
```

Protect user and device access

11/2/2020 • 2 minutes to read • Edit Online

Protecting access to your Microsoft 365 data and services is crucial to defending against cyberattacks and guarding against data loss. The same protections can be applied to other SaaS applications in your environment and even to on-premises applications published with Azure Active Directory Application Proxy.

Step 1: Review recommendations

Recommended capabilities for protecting identities and devices that access Office 365, other SaaS services, and on-premises applications published with Azure AD Application Proxy.

PDF | Visio | More languages

Step 2: Protect administrator accounts and access

The administrative accounts you use to administer your Microsoft 365 environment include elevated privileges. These are valuable targets for hackers and cyberattackers.

Begin by using administrator accounts only for administration. Admins should have a separate user account for regular, non-administrative use and only use their administrative account when necessary to complete a task associated with their job function.

Protect your administrator accounts with multi-factor authentication and conditional access. For more information, see Protecting administrator accounts.

Next, configure privileged access management in Office 365. Privileged access management allows granular access control over privileged admin tasks in Office 365. It can help protect your organization from breaches that may use existing privileged admin accounts with standing access to sensitive data or access to critical configuration settings.

- Overview of privileged access management
- Configure privileged access management

Another top recommendation is to use workstations specifically configured for administrative work. These are dedicated devices that are only used for administrative tasks. See Securing privileged access.

Finally, you can mitigate the impact of inadvertent lack of administrative access by creating two or more emergency access accounts in your tenant. See Manage emergency access accounts in Azure AD.

Step 3: Configure recommended identity and device access policies

Multi-factor authentication (MFA) and conditional access policies are powerful tools for mitigating against compromised accounts and unauthorized access. We recommend implementing a set of policies that have been tested together. For more information, including deployment steps, see Identity and device access configurations.

These policies implement the following capabilities:

- Mult-factor authentication
- Conditional access
- Intune app protection (app and data protection for devices)

- Intune device compliance
- Azure AD Identity Protection

Implementing Intune device compliance requires device enrollment. Managing devices allows you to ensure that they are healthy and compliant before allowing them access to resources in your environment. See Enroll devices for management in Intune

Step 4: Configure SharePoint device access policies

Microsoft recommends you protect content in SharePoint sites with sensitive and highly-regulated content with device access controls. For more information, see Policy recommendations for securing SharePoint sites and files.

Customer Lockbox in Office 365

11/2/2020 • 12 minutes to read • Edit Online

This article provides deployment and configuration guidance for Customer Lockbox. Customer Lockbox supports requests to access data in Exchange Online, SharePoint Online, and OneDrive for Business. To recommend support for other services, please submit a request at Office 365 UserVoice.

To see the options for licensing your users to benefit from Microsoft 365 compliance offerings, including this one, as of April 1, 2020, see the Microsoft 365 licensing guidance for security & compliance.

Customer Lockbox ensures that Microsoft cannot access your content to perform a service operation without your explicit approval. Customer Lockbox brings you into the approval workflow for requests to access your content.

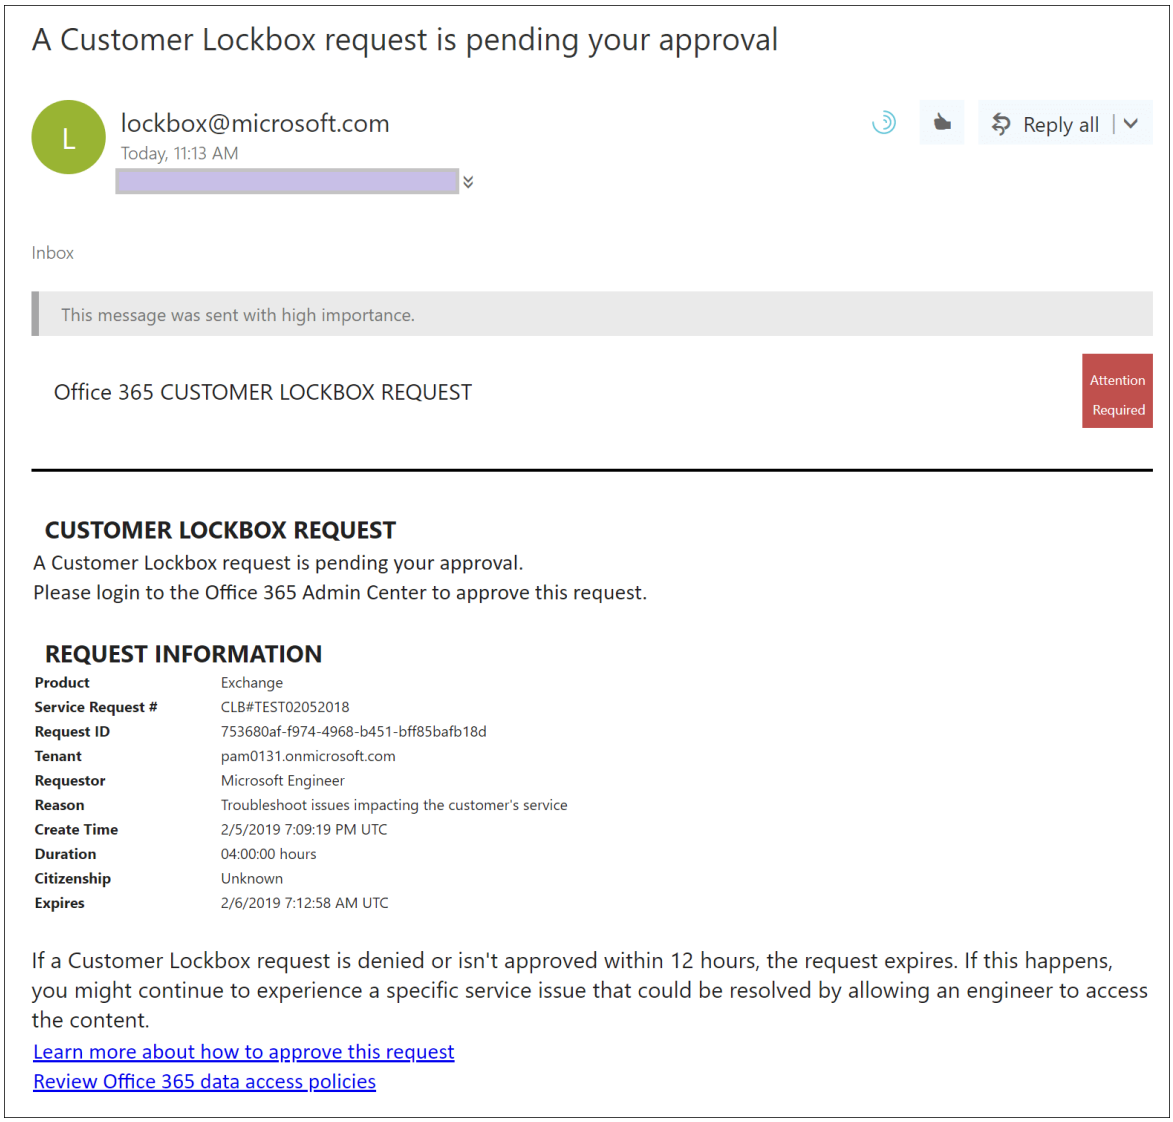
Occasionally, Microsoft engineers help troubleshoot and fix customer reported issues in the support process. Usually, issues are fixed through extensive telemetry and debugging tools Microsoft has in place for its services. However, some cases require a Microsoft engineer to access customer content to determine the root cause and fix the issue. Customer Lockbox requires the engineer to request access from the customer as a final step in the approval workflow. This gives organizations the option to approve or deny these requests, and provide direct-access control to the customer.

Customer Lockbox overview video

Customer Lockbox workflow

The following steps outline the typical workflow when a Microsoft engineer initiates a Customer Lockbox request:

1. Someone at an organization experiences an issue with their Microsoft 365 mailbox.
2. After the user troubleshoots the issue, but can't fix it, they open a support request with Microsoft Support.
3. A Microsoft support engineer reviews the service request and determines a need to access the organization's tenant to repair the issue in Exchange Online.
4. The Microsoft support engineer logs into the Customer Lockbox request tool and makes a data access request that includes the organization's tenant name, service request number, and the estimated time the engineer needs access to the data.
5. After a Microsoft Support manager approves the request, Customer Lockbox sends the designated approver at the organization an email notification about the pending access request from Microsoft.



Anyone who is assigned the Customer Lockbox access approver admin role in Microsoft 365 admin center can approve Customer Lockbox requests.

6. The approver signs in to the Microsoft 365 admin center and approves the request. This step triggers the creation of an audit record available by searching the audit log. For more information, see Auditing Customer Lockbox requests.

   If the customer rejects the request or doesn't approve the request within 12 hours, the request expires and no access is granted to the Microsoft engineer.

   > **IMPORTANT**
   > Microsoft does not include any links in Customer Lockbox email notifications requiring you to sign in to Office 365.

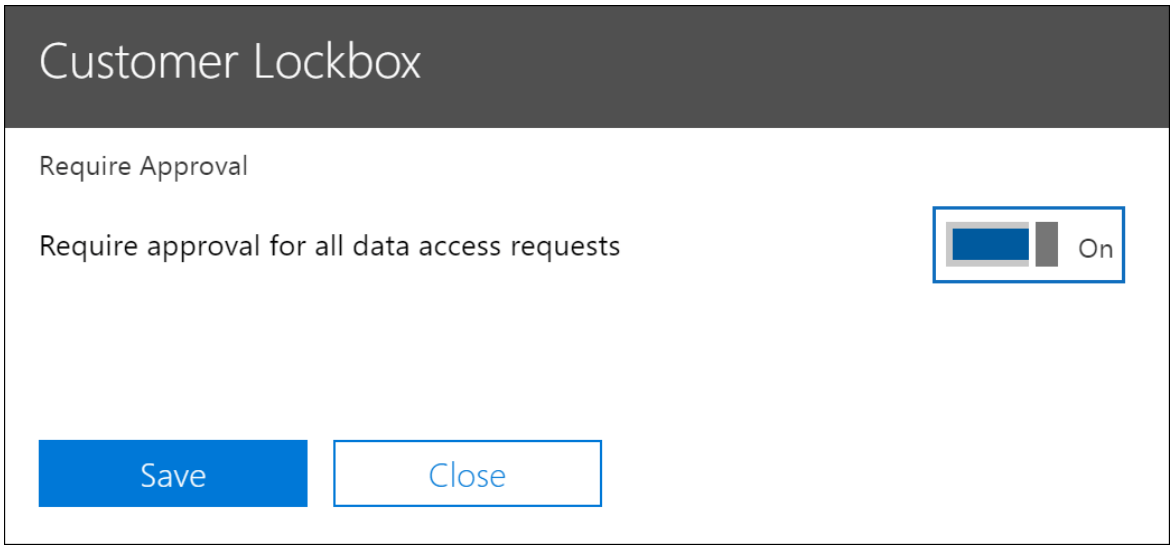
7. After the approver from the organization approves the request, the Microsoft engineer receives the approval message, logs into the tenant in Exchange Online, and fixes the customer's issue. Microsoft engineers have the requested duration to fix the issue after which the access is automatically revoked.

> **NOTE**
> All actions performed by a Microsoft engineer are logged in the audit log. You can search for and review these audit records.

Turn Customer Lockbox requests on or off

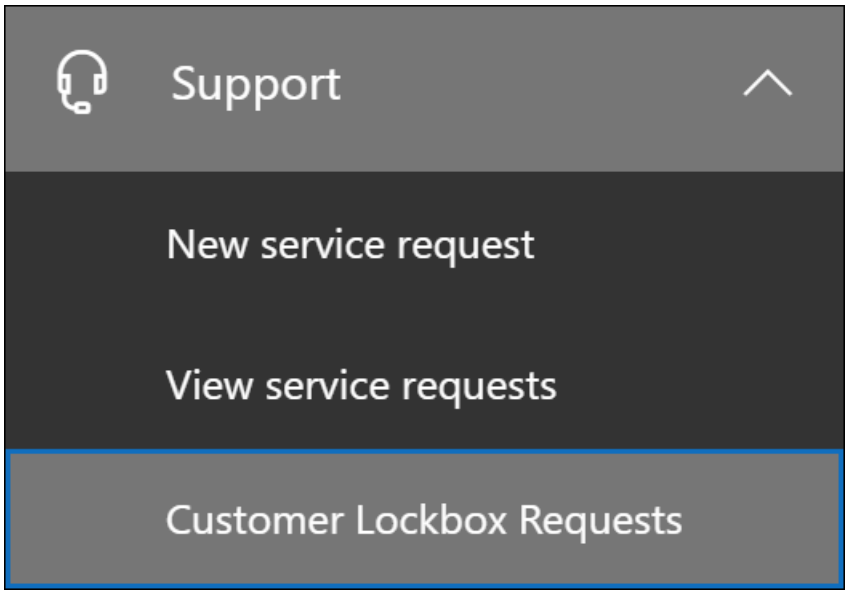
You can turn on Customer Lockbox controls in the Microsoft 365 admin center. When you turn on Customer Lockbox, Microsoft must obtain your organization's approval before accessing any of your tenant's content.

1. Using a work or school account that has either the global administrator or the **Customer Lockbox access approver** role assigned, go to https://admin.microsoft.com and sign in.
2. Choose **Settings** > **Org Settings**.
3. Select **Security & Privacy** > **Customer Lockbox** > **Edit**, and then move the toggle to **On** or **Off** to turn the feature on or off.

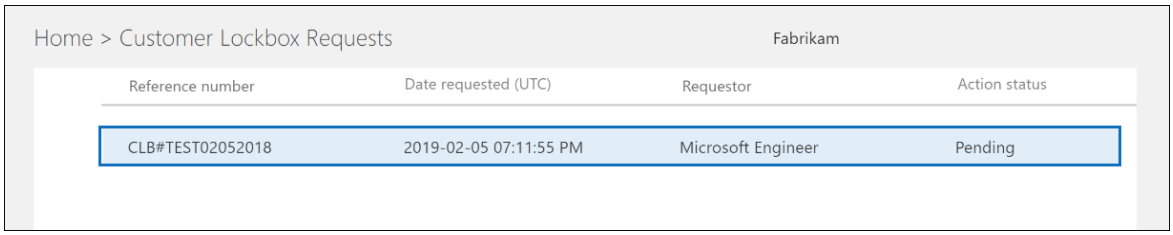


Approve or deny a Customer Lockbox request

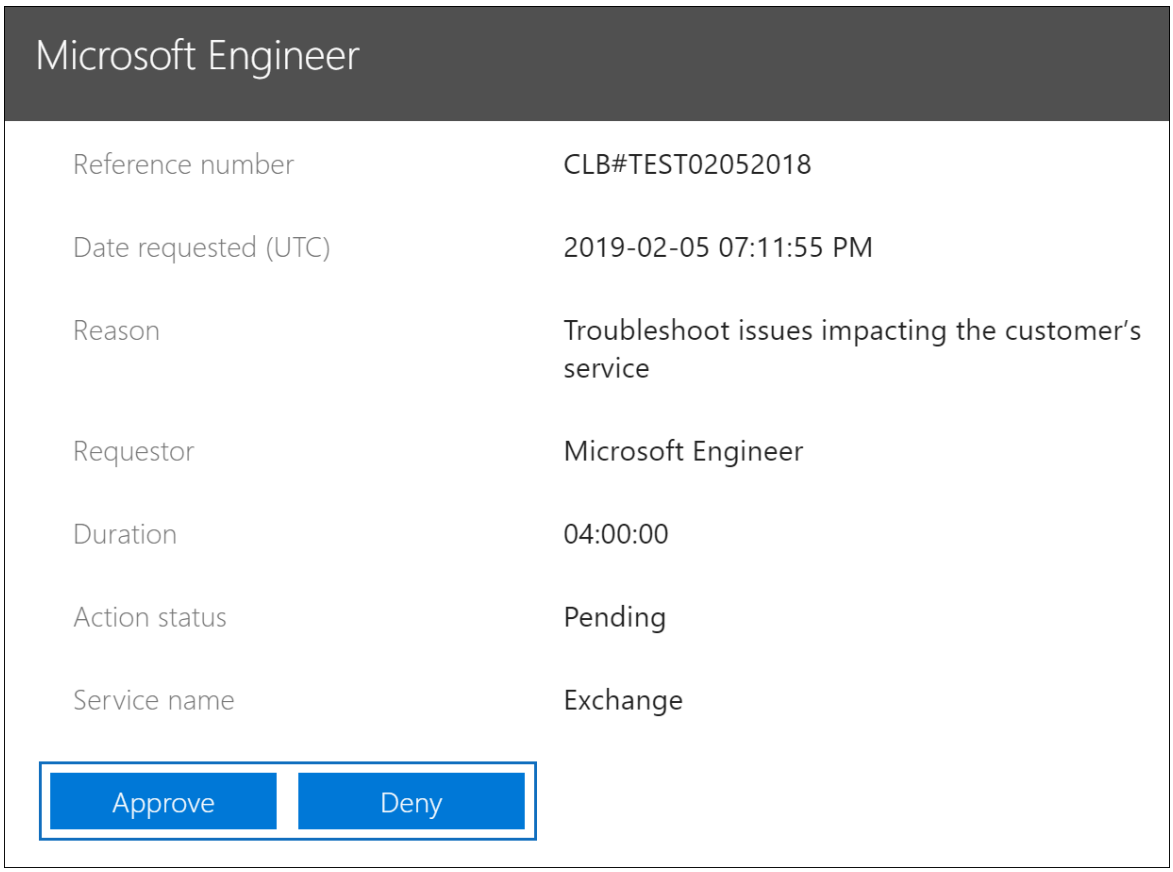
1. Using a work or school account that has either the global administrator or the **Customer Lockbox access approver** role assigned, go to https://admin.microsoft.com and sign in.
2. Choose **Support** > **Customer Lockbox Requests**.



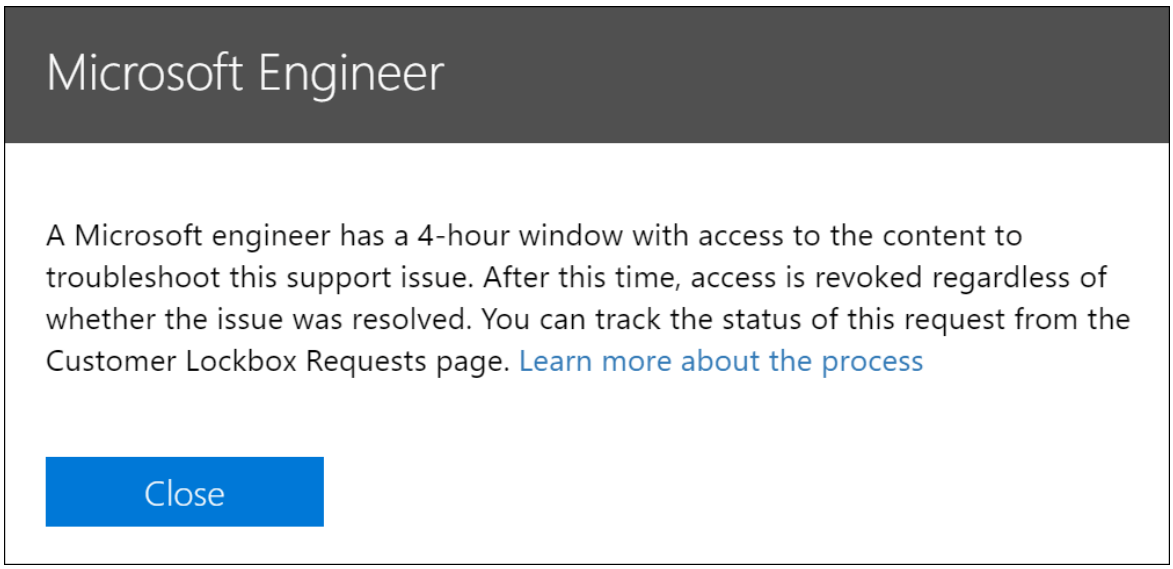
A list of Customer Lockbox requests displays.



3. Select a Customer Lockbox request, and then choose **Approve** or **Deny**.



A confirmation message about the approval of the Customer Lockbox request displays.



NOTE

Use the Set-AccessToCustomerDataRequest cmdlet to approve, deny, or cancel Microsoft 365 customer lockbox requests that control access to your data by Microsoft support engineers. For more information, see Set-AccessToCustomerDataRequest.

Auditing Customer Lockbox requests

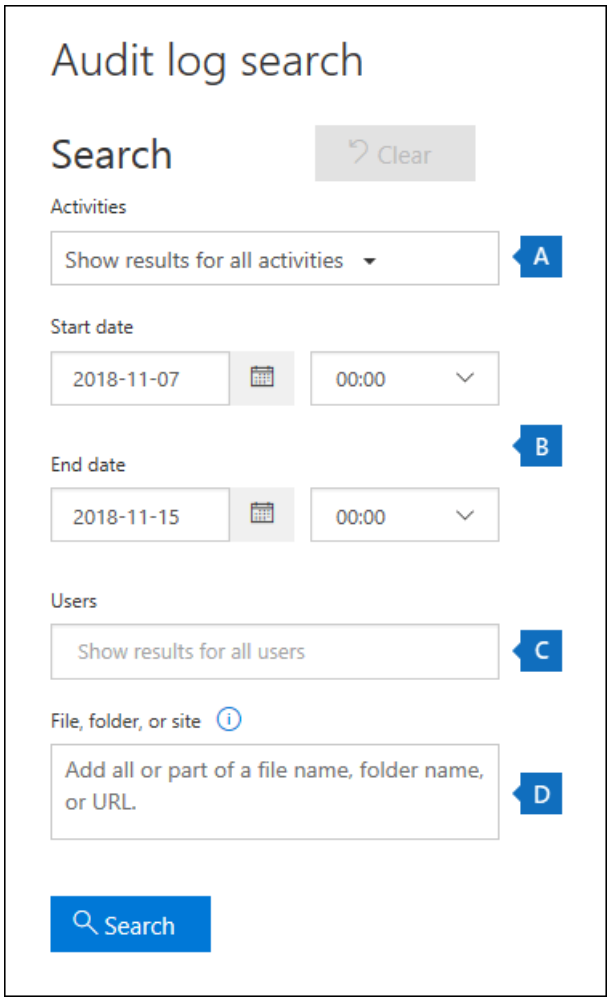
Audit records that correspond to the Customer Lockbox requests are logged in the audit log. You can access these logs by using the audit log search tool in the Security & Compliance Center. Actions related to accepting or denying a Customer Lockbox request and actions performed by Microsoft engineers (when access requests are approved) are also logged in the audit log. You can search for and review these audit records.

Search the audit log for activity related to Customer Lockbox requests

Before you can use the audit log to track requests for Customer Lockbox, there are some steps you need to take to set up audit logging. For more information, see Search the audit log in the Security & Compliance Center. Once you've completed setup, use these steps to create an audit log search query to return audit records related to Customer Lockbox:

1. Go to https://protection.office.com.
2. Sign in using your work or school account.
3. In the left pane of the Security & Compliance Center, choose **Search & investigation** > **Audit log search**.

   The **Audit log search** page displays.



4. Configure the following search criteria:

    a. **Activities** - Leave this field blank so that the search returns audit records for all activities. This is necessary to return any audit records related to Customer Lockbox requests and corresponding activity performed by Microsoft engineers.

    b. **Start date** and **End date** - Select a date and time range to display the events that occurred within that period.

    c. **Users** - Leave this field blank.

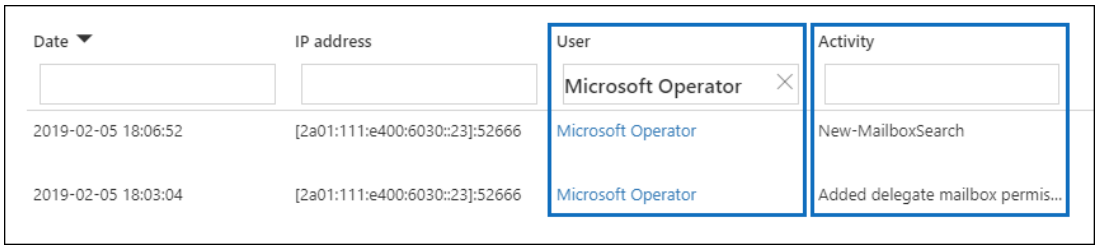
    d. **File, folder, or site** - Leave this field blank.

5. Click **Search** to run the search using your search criteria.

    The search results are loaded, and after a few moments they are displayed under **Results** on the **Audit log search** page.

6. Click **Filter results** on the search results page, and do one of the following things:

    - To display audit records related to an approver in your organization approving or denying a Customer Lockbox request: In the box under the **Activity** column, type **Set-AccessToCustomerDataRequest**.
    - To display audit records related to a Microsoft engineer performing actions in response to an approved Customer Lockbox request: In the box under the **User** column, type **Microsoft Operator**. The **Activity** column displays the action performed by the engineer.



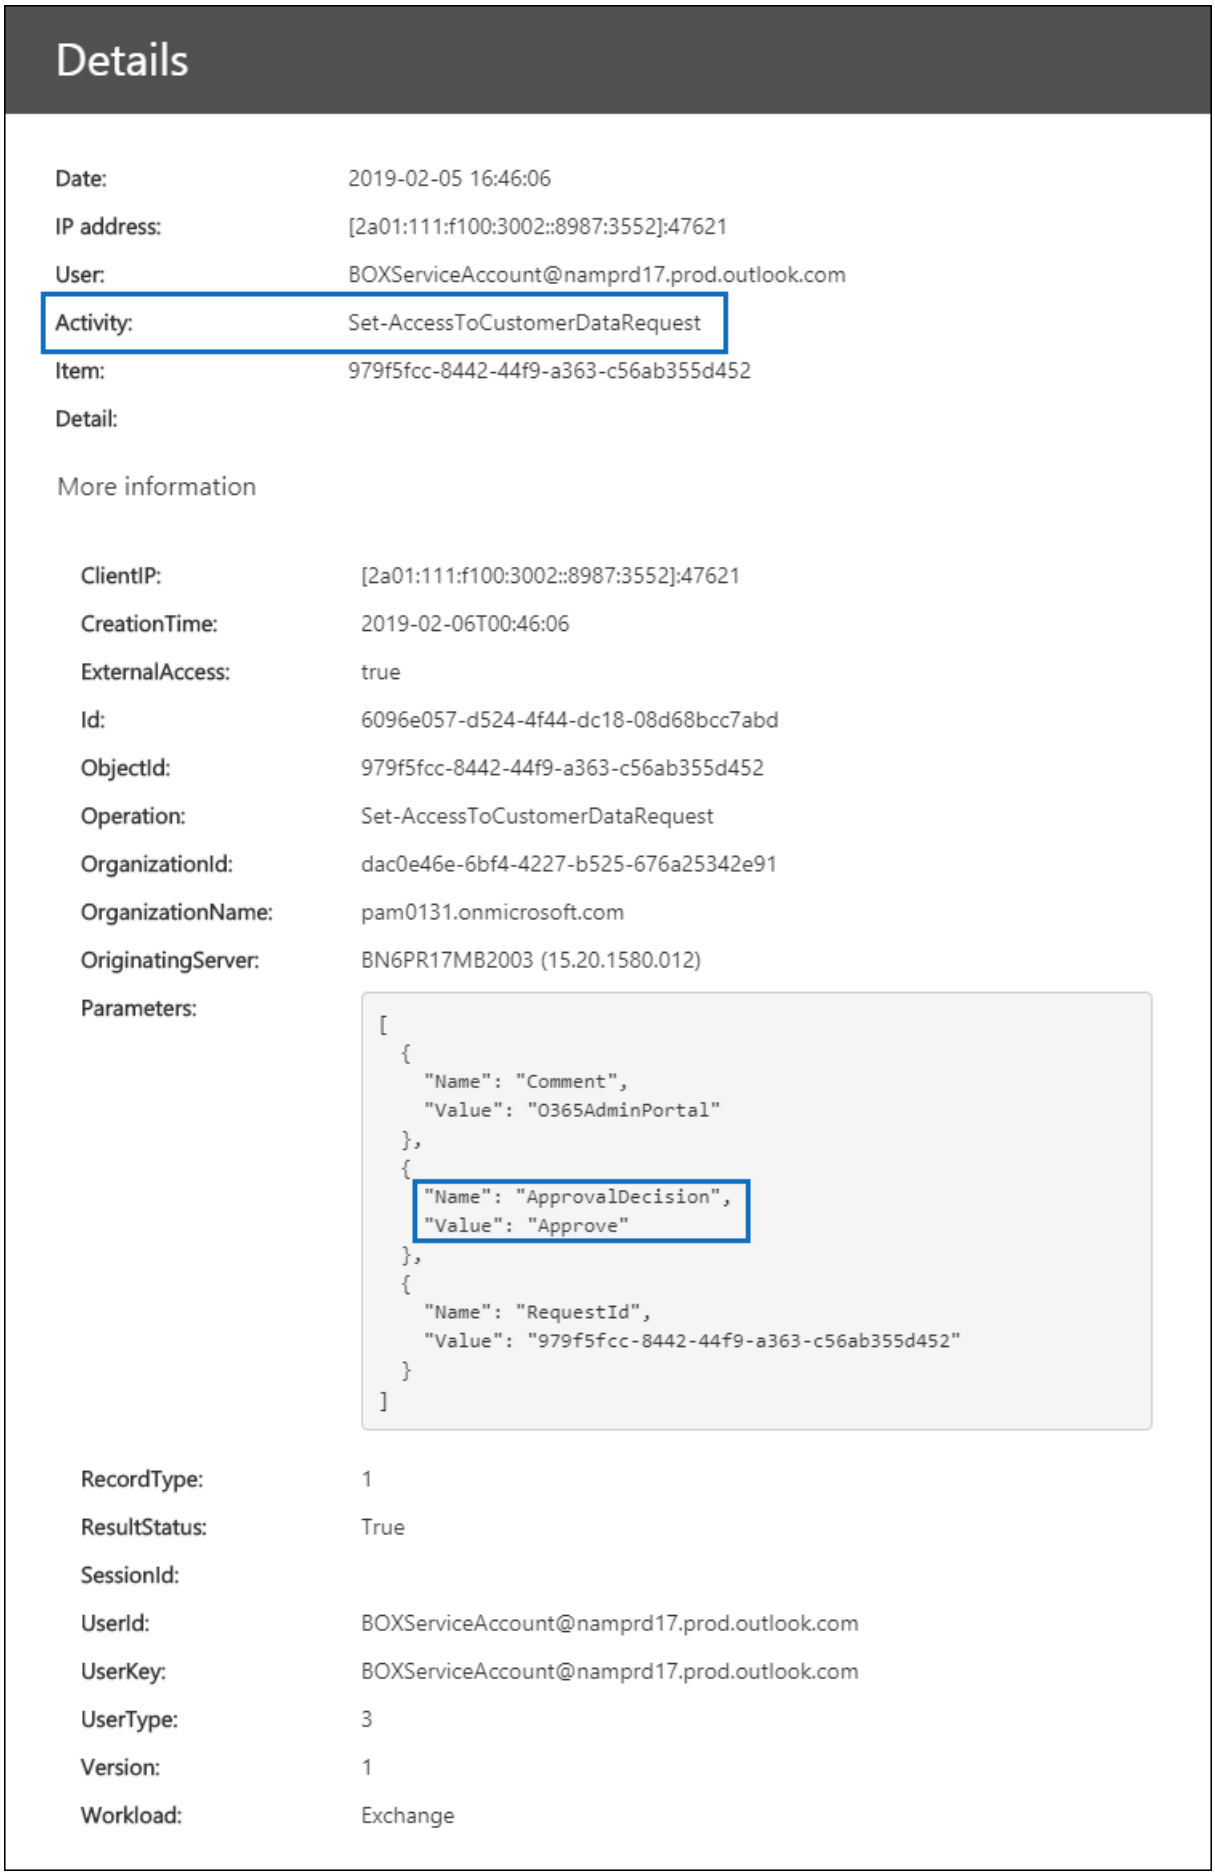
7. In the list of results, click an audit record to display it.

Audit record for a Customer Lockbox access request

When a person in your organization approves or denies a Customer Lockbox request, an audit record is logged in the audit log. This record contains the following information.

AUDIT RECORD PROPERTY	DESCRIPTION
Date	The date and time when the Customer Lockbox request was approved or denied.
IP address	The IP address of the machine the approver used to approve or deny a request.
User	The service account BOXServiceAccount@[customerforest].prod.outlook.com.
Activity	Set-AccessToCustomerDataRequest; this is the auditing activity that is logged when you approve or deny a Customer Lockbox request.
Item	The Guid of the Customer Lockbox request

The following screenshot shows an example of an audit log record that corresponds to an approved Customer Lockbox request. If a Customer Lockbox request was denied, then the value of **ApprovalDecision** parameter would be **Deny**.



TIP

To display more detailed information in an audit record, click **More information**.

Audit record for an action performed by a Microsoft engineer

The actions performed by a Microsoft engineer after a Customer Lockbox request is approved (and that may result in accessing customer content) are logged in the audit log. These records contain the following information.

AUDIT RECORD PROPERTY	DESCRIPTION
Date	Date time when the action was performed. Note that the time that this action was performed will be within 4 hours of when the Customer Lockbox request was approved.
IP address	The IP Address of the machine Microsoft engineer used.
User	Microsoft Operator; this value indicates that this record is related to a Customer Lockbox request.
Activity	Name of the activity performed by the Microsoft engineer.
Item	<empty>

Frequently asked questions

Which Microsoft 365 services does Customer Lockbox apply to?

Customer Lockbox is currently supported in Exchange Online, SharePoint Online, and OneDrive for Business.

Is Customer Lockbox available to all customers?

Customer Lockbox is included with the Microsoft 365 or Office 365 E5 subscriptions and can be added to other plans with an Information Protection and Compliance or an Advanced Compliance add-on subscription. Please see Plans and pricing for more information.

What is customer content?

Customer content is the data created by users of Microsoft 365 services and applications. Examples of customer content include:

- Email body or email attachments
- SharePoint site contents
- Information in the body of a SharePoint file
- Skype for Business presentation file body
- Instant messages (IM) or voice conversations
- Customer-generated blob or structured storage data (for example, SQL Containers)
- Customer-owned security information (for example, certificates, encryption keys, and passwords)
- Inferences, and all subsequent inferences, if customer content remains

For additional information about customer content in Office 365, see the Office 365 Trust Center.

Who is notified when there is a request to access my content?

Global administrators and anyone assigned the Customer Lockbox access approver admin role are notified.

These are also the same users who can approve for Customer Lockbox requests.

Who can approve or reject these requests in my organization?

Global administrators and anyone assigned the Customer Lockbox access approver admin role can approve Customer Lockbox requests. Customers control these role assignments in their organizations.

How do I opt in to Customer Lockbox?

A global administrator can enable and configure Customer Lockbox in the Microsoft 365 or Microsoft 365 admin center.

If I approve a Customer Lockbox request, what can the engineer do and how will I know what the Microsoft engineer did?

After you approve a Customer Lockbox request, the Microsoft engineer granted these necessary privileges to access customer content by using pre-approved cmdlets. Actions taken by Microsoft engineers in response to Customer Lockbox requests are logged and accessible in the audit log in the Security & Compliance Center.

How do I know that Microsoft follows the approval process?

You can cross-reference the email approval notifications sent to admins and approvers in your organization with the Customer Lockbox request history in the Microsoft 365 admin center.

Customer Lockbox is included in the latest SOC 1 SSAE 16 audit report. For more details, you can find the latest reports in the Microsoft Service Trust Portal.

Can Microsoft modify the list of approvers for my tenant? If not, how is it prevented?

Only a global administrator in your organization can specify who can approve Customer Lockbox requests. That means only the members of the Global administrator group in Azure Active Directory can specify who can approve request. Membership of the Global administrator group in Azure Active Directory is managed only by your organization.

What if I need more information about a content access request to approve it?

Each Customer Lockbox request contains a Microsoft 365 service request number. You can contact Microsoft Support and reference this service number to get more information about the request.

When a Customer Lockbox request is approved, how long are the permissions valid?

Currently, the maximum period for the access permissions granted to the Microsoft engineer is 4 hours. The Microsoft engineer can also request a shorter period.

How can I get a history of all Customer Lockbox requests?

All Customer Lockbox requests are viewed in the Microsoft 365 admin center.

How do I correlate the content access requests with the related audit logs?

The Compliance Center Activity Feed contains log activities of Customer Lockbox. Customers can cross-reference the Customer Lockbox log activities from the activity feed against the email request they receive.

What happens when a customer doesn't respond to a Customer Lockbox request?

Customer Lockbox requests have a default duration of 12 hours. If you don't respond to a request within 12 hour, the request expires.

What does Microsoft do when a customer rejects a Customer Lockbox request?

If a customer rejects a Customer Lockbox request, no access to customer content occurs. If a user in your organization continues to experience a service issue requiring Microsoft to access customer content to resolve the issue, then the service issue might persist and Microsoft will inform the user about this.

Does Customer Lockbox protect against data requests from law enforcement agencies or other third parties?

No. Microsoft takes third-party requests for customer data seriously. As a cloud service provider, Microsoft always advocates for the privacy of customer data. In the event we get a subpoena, Microsoft always attempts to redirect the third party to the customer to obtain the information. (Read Brad Smith's blog: Protecting customer data from government snooping). We periodically publish detailed information about the law enforcement requests that Microsoft receives.

See the Microsoft Trust Center regarding third-party data requests and the "Disclosure of Customer Data" section in the Online Services Terms for more information.

How does Microsoft ensure that a member of its staff doesn't have standing access to customer content in Office 365 applications?

Microsoft implements extensive preventive measures through access control systems, and detective measures to identify and address attempts to circumvent these access control systems. Microsoft 365 operates with the principles of least privilege and just-in-time access. Therefore, no Microsoft personnel have permission to access customer content on an ongoing basis. If permission is granted, it is for a limited duration.

Microsoft 365 uses an access control system called *Lockbox* to process requests for permissions that grant the ability to perform operational and administrative functions within the service. An operator must request access to customer content using Lockbox, which then requires a second person to take action on the request (e.g., approve it) before access is granted. That second person can't be the requestor and must be designated to approve access to customer content. Only if the request is approved does the operator acquire temporary access to customer content. After the elevation period expires, Lockbox revokes access.

Please refer to the Online Services Terms for more details about Microsoft general security practices.

Under what circumstances do Microsoft engineers need access to my content?

The most common scenario where Microsoft engineers need access customer content is when the customer makes a support request requiring access for troubleshooting. A foundational principle of Microsoft 365 is that the service operates without Microsoft access to customer content. Nearly all service operations performed by Microsoft are fully automated and human involvement is highly controlled and abstracted away from customer content. The goal for Microsoft 365 is access to customer content to support the service isn't needed until the customer approves a specific request for Microsoft access.

I already thought my data was secure with the Microsoft cloud, so why do I need Customer Lockbox?

Customer Lockbox provides an extra layer of control by offering customers the ability to give explicit access authorization for service operations. By demonstrating that procedures are in place for explicit data access authorization, Customer Lockbox also helps customers meet certain compliance obligations such as HIPAA and FEDRAMP.

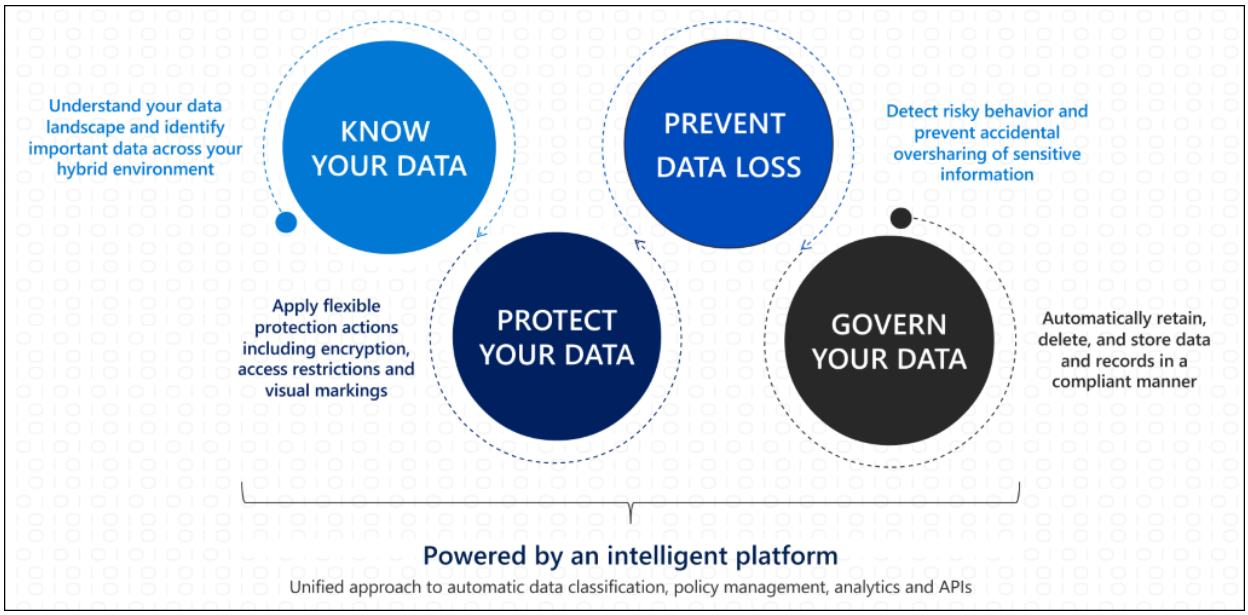
Microsoft Information Protection in Microsoft 365

2/18/2021 • 3 minutes to read • Edit Online

Licensing for Microsoft 365 Security & Compliance

Implement Microsoft Information Protection (MIP) to help you discover, classify, and protect sensitive information wherever it lives or travels.

MIP capabilities are included with Microsoft 365 Compliance and give you the tools to know your data, protect your data, and prevent data loss.



For information about governing your data, see Microsoft Information Governance in Microsoft 365.

Know your data

NOTE

For information about classifying and labeling data in Azure Purview, currently in preview, see Automatically label your content in Azure Purview.

For information about this recent release, see the blog post Microsoft Information Protection and Microsoft Azure Purview: Better Together.

To understand your data landscape and identify important data across your hybrid environment, use the following capabilities:

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Sensitive information types	Identifies sensitive data by using built-in or custom regular expressions or a function. Corroborative evidence includes keywords, confidence levels, and proximity.	Customize a built-in sensitive information type

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Trainable classifiers	Identifies sensitive data by using examples of the data you're interested in rather than identifying elements in the item (pattern matching). You can use built-in classifiers or train a classifier with your own content.	Get started with trainable classifiers
Data classification	A graphical identification of items in your organization that have a sensitivity label, a retention label, or have been classified. You can also use this information to gain insights into the actions that your users are taking on these items.	Get started with content explorer Get started with activity explorer

Protect your data

To apply flexible protection actions that include encryption, access restrictions, and visual markings, use the following capabilities:

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Sensitivity labels	A single solution across apps, services, and devices to label and protect your data as it travels inside and outside your organization. Example scenarios: Manage sensitivity labels for Office apps Encrypt documents and emails Apply and view labels in Power BI For a comprehensive list of scenarios for sensitivity labels, see the Get started documentation.	Get started with sensitivity labels
Azure Information Protection unified labeling client	For Windows computers, extends sensitivity labels for additional features and functionality that includes labeling and protecting all file types from File Explorer and PowerShell Example additional features: Custom configurations for the Azure Information Protection unified labeling client	Azure Information Protection unified labeling client administrator guide
Double Key Encryption	Under all circumstances, only your organization can ever decrypt protected content or for regulatory requirements, you must hold encryption keys within a geographical boundary.	Deploy Double Key Encryption

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Office 365 Message Encryption (OME)	Encrypts email messages and attached documents that are sent to any user on any device, so only authorized recipients can read emailed information. Example scenario: Revoke email encrypted by Advanced Message Encryption	Set up new Message Encryption capabilities
Service encryption with Customer Key	Protects against viewing of data by unauthorized systems or personnel, and complements BitLocker disk encryption in Microsoft datacenters.	Set up Customer Key for Office 365
SharePoint Information Rights Management (IRM)	Protects SharePoint lists and libraries so that when a user checks out a document, the downloaded file is protected so that only authorized people can view and use the file according to policies that you specify.	Set up Information Rights Management (IRM) in SharePoint admin center
Rights Management connector	Protection-only for existing on-premises deployments that use Exchange or SharePoint Server, or file servers that run Windows Server and File Classification Infrastructure (FCI).	Steps to deploy the RMS connector
Azure Information Protection unified labeling scanner	Discovers, labels, and protects sensitive information that resides in data stores that are on premises.	Configuring and installing the Azure Information Protection unified labeling scanner
Microsoft Cloud App Security	Discovers, labels, and protects sensitive information that resides in data stores that are in the cloud.	Discover, classify, label, and protect regulated and sensitive data stored in the cloud
Microsoft Information Protection SDK	Extends sensitivity labels to third-party apps and services. Example scenario: Set and get a sensitivity label (C++)	Microsoft Information Protection (MIP) SDK setup and configuration

Prevent data loss

To help prevent accidental oversharing of sensitive information, use the following capabilities:

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Data loss prevention (DLP)	Helps prevent unintentional sharing of sensitive items. Example scenario: Protect sensitive information in Microsoft Teams chat and channel messages	Get started with the default DLP policy

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Learn about Endpoint data loss prevention	Extends DLP capabilities to items that are used and shared on Windows 10 computers.	Get started with Endpoint data loss prevention

Learn about sensitive information types

2/18/2021 • 4 minutes to read • Edit Online

Identifying and classifying sensitive items that are under your organizations control is the first step in the Information Protection discipline. Microsoft 365 provides three ways of identifying items so that they can be classified:

- manually by users
- automated pattern recognition, like sensitive information types
- machine learning

Sensitive information types are pattern-based classifiers. They detect sensitive information like social security, credit card, or bank account numbers to identify sensitive items, see Sensitive information types entity definitions

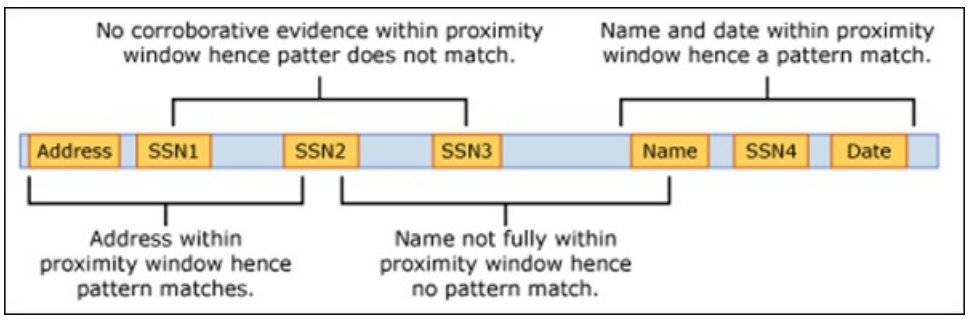
Sensitive information types are used in

- Data loss prevention policies
- Sensitivity labels
- Retention labels
- Communication compliance
- Auto-labelling policies

Fundamental parts of a sensitive information type

Every sensitive information type entity is defined by these fields:

- name: how the sensitive information type is referred to
- description: describes what the sensitive information type is looking for
- pattern: A pattern defines what a sensitive information type detects. It consists of the following components
  - Primary element – the main element that the sensitive information type is looking for. It can be a **regular expression** with or without a checksum validation, a **keyword list**, a **keyword dictionary**, or a **function**.
  - Supporting element – elements that act as supporting evidence that help in increasing the confidence of the match. For example, keyword "SSN" in proximity of an SSN number. It can be a regular expression with or without a checksum validation, keyword list, keyword dictionary.
  - Confidence Level - Confidence levels (high, medium, low) reflect how much supporting evidence was detected along with the primary element. The more supporting evidence an item contains, the higher the confidence that a matched item contains the sensitive info you're looking for.
  - Proximity – Number of characters between primary and supporting element



Learn more about confidence levels in this video

Example sensitive information type

Argentina national identity (DNI) number

Format

Eight digits separated by periods

Pattern

Eight digits:

- two digits
- a period
- three digits
- a period
- three digits

Checksum

No

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression Regex_argentina_national_id finds content that matches the pattern.
- A keyword from Keyword_argentina_national_id is found.

```
<!-- Argentina National Identity (DNI) Number -->
<Entity id="eefbb00e-8282-433c-8620-8f1da3bffdb2" recommendedConfidence="75" patternsProximity="300">
   <Pattern confidenceLevel="75">
      <IdMatch idRef="Regex_argentina_national_id"/>
      <Match idRef="Keyword_argentina_national_id"/>
  </Pattern>
</Entity>
```

Keywords

Keyword_argentina_national_id

- Argentina National Identity number
- Identity
- Identification National Identity Card
- DNI
- NIC National Registry of Persons
- Documento Nacional de Identidad
- Registro Nacional de las Personas
- Identidad
- Identificación

More on confidence levels

In a sensitive information type entity definition, **confidence level** reflects how much supporting evidence is detected in addition to the primary element. The more supporting evidence an item contains, the higher the confidence that a matched item contains the sensitive info you're looking for. For example, matches with a high

confidence level will contain more supporting evidence in close proximity of the primary element, whereas matches with a low confidence level would contain little to no supporting evidence in close proximity.

A high confidence level returns the fewest false positives but might result in more false negatives. Low or medium confidence levels returns more false positives but few to zero false negatives.

- **low confidence**: value of 65, matched items will contain the fewest false negatives but the most false positives.
- **medium confidence**: value of 75, matched items will contain an average amount of false positives and false negatives.
- **high confidence**: value of 85, matched items will contain the fewest false positives but the most false negatives.

You should use high confidence level patterns with low counts, say five to ten, and low confidence patterns with higher counts, say 20 or more.

Creating custom sensitive information types

To create custom sensitive information types in the Security & Compliance Center, you can choose from several options:

- **Use the UI** You can set up a custom sensitive information type using the Security & Compliance Center UI. With this method, you can use regular expressions, keywords, and keyword dictionaries. To learn more, see Create a custom sensitive information type.
- **Use EDM** You can set up custom sensitive information types using Exact Data Match (EDM)-based classification. This method enables you to create a dynamic sensitive information type using a secure database that you can refresh periodically. See Create a custom sensitive information type with Exact Data Match based classification.
- **Use PowerShell** You can set up custom sensitive information types using PowerShell. Although this method is more complex than using the UI, you have more configuration options. See Create a custom sensitive information type in Security & Compliance Center PowerShell.

> **NOTE**
> Improved confidence levels are available for immediate use within Data Loss Prevention for Microsoft 365 services, Microsoft Information Protection for Microsoft 365 services, Communication Compliance, Information Governance, and Records Management.

> Microsoft 365 Information Protection now supports in preview double byte character set languages for:
>
> - Chinese (simplified)
> - Chinese (traditional)
> - Korean
> - Japanese

> This support is available for sensitive information types. See, Information protection support for double byte character sets release notes (preview) for more information.

For further information

- Sensitive information type entity definitions
- Create a custom sensitive information type

- Create a custom sensitive information type in PowerShell

Sensitive information type entity definitions

2/18/2021 • 192 minutes to read • Edit Online

Data loss prevention (DLP) in the Compliance Center includes many sensitive information types that are ready to use in your DLP policies. This article lists all of these sensitive information types and shows what a DLP policy looks for when it detects each type. A sensitive information type is defined by a pattern that can be identified by a regular expression or a function. Corroborative evidence, like keywords and checksums, can be used to identify a sensitive information type. Confidence level and proximity are also used in the evaluation process.

Sensitive information types require one of these subscriptions:

- Microsoft 365 E3
- Microsoft 365 E5

Sensitive information types are used in:

- Data loss prevention policies
- Sensitivity labels
- Retention labels
- Communication compliance
- Auto-labelling policies

ABA routing number

Format

nine digits that may be in a formatted or unformatted pattern

Pattern

Formatted:

- four digits beginning with 0, 1, 2, 3, 6, 7, or 8
- a hyphen
- four digits
- a hyphen
- a digit

Unformatted: nine consecutive digits beginning with 0, 1, 2, 3, 6, 7, or 8

Checksum

No

Definition

A policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_aba_routing finds content that matches the pattern.
- A keyword from Keyword_ABA_Routing is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_aba_routing finds content that matches the pattern.

```
<!-- ABA Routing Number -->
<Entity id="cb353f78-2b72-4c3c-8827-92ebe4f69fdf" patternsProximity="300" recommendedConfidence="75">

Azure IAAS database connection string and Azure SQL connection string

Format

The string "Server", "server", or "data source" followed by the characters and strings outlined in the pattern below, including the string "cloudapp.azure.com" or "cloudapp.azure.net" or "database.windows.net", and the

string "Password" or "password" or "pwd".

Pattern

- the string "Server", "server", or "data source"
- zero to two whitespace characters
- an equal sign (=)
- zero to two whitespace characters
- any combination of between 1-200 lower- or uppercase letters, digits, symbols, special characters, or spaces
- The string "cloudapp.azure.com", "cloudapp.azure.net", or "database.windows.net"
- any combination of between 1-300 lower- or uppercase letters, digits, symbols, special characters, or spaces
- the string "Password", "password", or "pwd"
- zero to two whitespace characters
- an equal sign (=)
- zero to two whitespace characters
- one or more characters that aren't a semicolon (;), quotation mark ("), or apostrophe (')
- a semicolon (;), quotation mark ("), or apostrophe (')

Checksum

No

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression CEP_Regex_AzureConnectionString finds content that matches the pattern.
- The regular expression CEP_CommonExampleKeywords doesn't find content that matches the pattern.

```
<!--Azure IAAS Database Connection String and Azure SQL Connection String-->
<Entity id="ce1a126d-186f-4700-8c0c-486157b953fd" patternsProximity="300" recommendedConfidence="85">

China resident identity card (PRC) number

Format

18 digits

Pattern

18 digits:

- six digits that are an address code
- eight digits in the form YYYYMMDD, which are the date of birth
- three digits that are an order code
- one digit that is a check digit

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_china_resident_id finds content that matches the pattern.
- A keyword from Keyword_china_resident_id is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_china_resident_id finds content that matches the pattern.
- The checksum passes.

Credit card number

Format

14 to 16 digits that can be formatted or unformatted (ddddddddddddddd) and that must pass the Luhn test.

Pattern

Complex and robust pattern that detects cards from all major brands worldwide, including Visa, MasterCard, Discover Card, JCB, American Express, gift cards, and diner cards.

Checksum

Yes, the Luhn checksum

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_credit_card finds content that matches the pattern.
- One of the following is true:
  - A keyword from Keyword_cc_verification is found.
  - A keyword from Keyword_cc_name is found.
  - The function Func_expiration_date finds a date in the right date format.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_credit_card finds content that matches the pattern.
- The checksum passes.

```

Cyprus tax identification number

This sensitive information type is only available for use in:

- data loss prevention policies
- communication compliance policies
- information governance
- records management
- Microsoft cloud app security

Format

eight digits and one letter in the specified pattern

Pattern

eight digits and one letter:

- a "0" or "9"
- seven digits
- one letter (not case-sensitive)

Checksum

not applicable

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_cyprus_eu_tax_file_number` finds content that matches the pattern.
- A keyword from `Keywords_cyprus_eu_tax_file_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_cyprus_eu_tax_file_number` finds content that matches the pattern.

Estonia Personal Identification Code

This sensitive information type is only available for use in:

- data loss prevention policies
- communication compliance policies
- information governance
- records management
- Microsoft cloud app security

Format

11 digits without spaces and delimiters

Pattern

11 digits:

- one digit that corresponds to sex and century of birth (odd number male, even number female; 1-2: 19th century; 3-4: 20th century; 5-6: 21st century)
- six digits that correspond to date of birth (YYMMDD)
- three digits that correspond to a serial number separating persons born on the same date
- one check digit

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_estonia_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_estonia_eu_national_id_card` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_estonia_eu_national_id_card` finds content that matches the pattern.

Greece national ID card

Format

Combination of 7-8 letters and numbers plus a dash

Pattern

Seven letters and numbers (old format):

- One letter (any letter of the Greek alphabet)
- A dash
- Six digits

Eight letters and numbers (new format):

- Two letters whose uppercase character occurs in both the Greek and Latin alphabets (ABEZHIKMNOPTYX)
- A dash
- Six digits

Checksum

No

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression Regex_greece_id_card finds content that matches the pattern.
- A keyword from Keyword_greece_id_card is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression Regex_greece_id_card finds content that matches the pattern.

```

Italy fiscal code

This sensitive information type is only available for use in:

- data loss prevention policies
- communication compliance policies
- information governance
- records management
- Microsoft cloud app security

Format

a 16-character combination of letters and digits in the specified pattern

Pattern

A 16-character combination of letters and digits:

- three letters that correspond to the first three consonants in the family name
- three letters that correspond to the first, third, and fourth consonants in the first name
- two digits that correspond to the last digits of the birth year
- one letter that corresponds to the letter for the month of birth—letters are used in alphabetical order, but only the letters A to E, H, L, M, P, R to T are used (so, January is A and October is R)
- two digits that correspond to the day of the month of birth—in order to differentiate between genders, 40 is added to the day of birth for women
- four digits that correspond to the area code specific to the municipality where the person was born (country-wide codes are used for foreign countries)
- one parity digit

Checksum

Yes

Italy passport number

Format

two letters or digits followed by seven digits with no spaces or delimiters

Pattern

two letters or digits followed by seven digits:

- two digits or letters (not case-sensitive)
- seven digits

Checksum

not applicable

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_italy_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_italy_eu_passport_number` is found.
- The regular expression `Regex_italy_eu_passport_date` finds date in the format DD MMM/MMM YYYY (Example - 01 GEN/JAN 1988) or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_italy_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_italy_eu_passport_number` is found.

```

Pattern

11 digits:

- six digits in the format DDMMYY which are the date of birth
- three-digit individual number
- two check digits

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_norway_id_number finds content that matches the pattern.
- A keyword from Keyword_norway_id_number is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_norway_id_numbe finds content that matches the pattern.
- The checksum passes.

```
<!-- Norway Identification Number -->

Poland passport number

This sensitive information type entity is included in the EU Passport Number sensitive information type. It's available as a stand-alone sensitive information type entity.

Format

two letters and seven digits

Pattern

Two letters (not case-sensitive) followed by seven digits

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_polish_passport_number_v2` finds content that matches the pattern.
- The checksum passes.
- A keyword from `Keywords_eu_passport_number` or `Keyword_polish_national_passport_number` is found.
- A keyword from `Keywords_eu_passport_date` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_polish_passport_number_v2` finds content that matches the pattern.
- The checksum passes.
- A keyword from `Keywords_eu_passport_number` or `Keyword_polish_national_passport_number` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_polish_passport_number_v2` finds content that matches the pattern.
- The checksum passes.

```

Romania personal numeric code (CNP)

This sensitive information type is only available for use in:

- data loss prevention policies
- communication compliance policies
- information governance
- records management
- Microsoft cloud app security

Format

13 digits without spaces and delimiters

Pattern

- one digit from 1-9
- six digits representing date of birth (YYMMDD)
- two digits, which can be 01-52 or 99
- four digits

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_romania_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_romania_eu_national_id_card` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_romania_eu_national_id_card` finds content that matches the pattern.

SQL Server connection string

Format

The string "User Id", "User ID", "uid", or "UserId" followed by the characters and strings outlined in the pattern below.

Pattern

- the string "User Id", "User ID", "uid", or "UserId"
- any combination of between 1-200 lower- or uppercase letters, digits, symbols, special characters, or spaces
- the string "Password" or "pwd" where "pwd" isn't preceded by a lowercase letter
- an equal sign (=)
- any character that isn't a dollar sign ($), percent symbol (%), greater than symbol (>), at symbol (@), quotation mark ("), semicolon (;), left brace([), or left bracket ({)
- any combination of 7-128 characters that are not a semicolon (;), forward slash (/), or quotation mark (")
- a semicolon (;) or quotation mark (")

Checksum

No

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression CEP_Regex_SQLServerConnectionString finds content that matches the pattern.
- A keyword from CEP_GlobalFilter isn't found.

Sweden national ID

Format

10 or 12 digits and an optional delimiter

Pattern

10 or 12 digits and an optional delimiter:

- two digits (optional)
- Six digits in date format YYMMDD
- delimiter of "-" or "+" (optional)
- four digits

Checksum

Yes

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swedish_national_identifier` finds content that matches the pattern.
- A keyword from `Keywords_swedish_national_identifier` is found
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swedish_national_identifier` finds content that matches the pattern.
- The checksum passes.

Sweden social security number or equivalent identification

This sensitive information type entity is only available in the EU Social Security Number or Equivalent ID sensitive information type.

Format

12 digits without spaces and delimiters

Pattern

12 digits:

- eight digits that correspond to the birth date (YYYYMMDD)
- three digits that correspond to a serial number where:
  - the last digit in the serial number indicates gender by the assignment of an odd number for male and an even number for female
  - Before 1990, the assignment of a serial number corresponded to the county where the bearer of the number was born. Or (if born before 1947) where they had been living, according to tax records, on January 1, 1947, with a special code (usually 9 as the seventh digit) for immigrants.
- one check digit

Checksum

Yes

Definition

A DLP policy is 85% confident that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_sweden_eu_ssn_or_equivalent` finds content that matches the pattern.
- A keyword from `Keywords_sweden_eu_ssn_or_equivalent` is found.

A DLP policy is 75% confident that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_sweden_eu_ssn_or_equivalent` finds content that matches the pattern.

Sweden tax identification number

This sensitive information type is only available for use in:

- data loss prevention policies
- communication compliance policies
- information governance
- records management
- Microsoft cloud app security

Format

10 digits and a symbol in the specified pattern

Pattern

10 digits and a symbol:

- six digits that correspond to the birth date (YYMMDD)
- a plus sign or minus sign
- three digits that make the identification number unique where:
  - for numbers issued before 1990, the seventh and eighth digit identify the county of birth or foreign-born people
  - the digit in the ninth position indicates gender by either odd for male or even for female
- one check digit

Checksum

Yes

U.K. national insurance number (NINO)

This sensitive information type entity is included in the EU National Identification Number sensitive information type. It's available as a stand-alone sensitive information type entity.

Format

seven characters or nine characters separated by spaces or dashes

Pattern

two possible patterns:

- two letters (valid NINOs use only certain characters in this prefix, which this pattern validates; not case-sensitive)
- six digits
- either 'A', 'B', 'C', or 'D' (like the prefix, only certain characters are allowed in the suffix; not case-sensitive)

OR

- two letters
- a space or dash

U.S. social security number (SSN)

Format

nine digits, which may be in a formatted or unformatted pattern

> **NOTE**
> If issued before mid-2011, an SSN has strong formatting where certain parts of the number must fall within certain ranges to be valid (but there's no checksum).

Pattern

four functions look for SSNs in four different patterns:

- Func_ssn finds SSNs with pre-2011 strong formatting that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- Func_unformatted_ssn finds SSNs with pre-2011 strong formatting that are unformatted as nine consecutive digits (ddddddddd)
- Func_randomized_formatted_ssn finds post-2011 SSNs that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- Func_randomized_unformatted_ssn finds post-2011 SSNs that are unformatted as nine consecutive digits (ddddddddd)

Checksum

No

What the DLP functions look for

11/2/2020 • 10 minutes to read • Edit Online

Data loss prevention (DLP) policies can use sensitive information types to identify sensitive items. Credit card number and EU debit card number are examples of sensitive information types. Sensitive information types look for specific patterns. Sensitive information types validate the data by looking at it's format, it's checksums, and looks for relevant keywords or other information. Some of this functionality is performed by internal functions. For example, the Credit Card Number sensitive information type uses a function to look for dates that are formatted like an expiration date. This helps to corroborate that a number is a credit card number.

This article explains what these functions look for, to help you understand how the predefined sensitive information types work. For more information, see Sensitive information type entity definitions

Table of functions

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_Argentina_Unique_Tax_Key	detects and validates Argentina Unique tax key	no	
Func_aba_routing	detects ABA routing number	yes

Func_us_date

Func_us_date looks for dates in common U.S. formats. The common formats are "month/day/year", "month-day-year", and "month day year ". The names or abbreviations of months aren't case-sensitive.

Examples:

- December 2, 2016
- Dec 2, 2016
- dec 02 2016
- 12/2/2016
- 12/02/16
- Dec-2-2016
- 12-2-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.

Func_eu_date

Fund_eu_dates looks for dates in common E.U. formats (and most places outside the U.S.), such as "day/month/year", "day-month-year", and "day month year". The names or abbreviations of months aren't case-sensitive.

Examples:

- 2 Dec 2016
- 02 dec 2016
- 2 Dec 16
- 2/12/2016
- 02/12/16
- 2-Dec-2016
- 2-12-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.
- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept oct okt nov dec
- French
  - janvier, février, mars, avril, mai, juin juillet, août, septembre, octobre, novembre, décembre
  - janv. févr. mars avril mai juin juil. août sept. oct. nov. déc.
- German
  - jänuar, februar, märz, April, mai, juni juli, August, September, oktober, November, dezember
  - Jan./Jän. Feb. März Apr. Mai Juni Juli Aug. Sept. Okt. Nov. Dez.
- Italian
  - gennaio, febbraio, marzo, aprile, maggio, giugno, luglio, agosto, settembre, ottobre, novembre, dicembre
  - genn. febbr. mar. apr. magg. giugno luglio ag. sett. ott. nov. dic.
- Portuguese

- janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
- jan fev mar abr mai jun jul ago set out nov dez

- Spanish
  - enero, febrero, marzo, abril, mayo, junio, julio, agosto, septiembre, octubre, noviembre, diciembre
  - enero feb. marzo abr. mayo jun. jul. agosto sept./set. oct. nov. dic.

Func_eu_date1 (deprecated)

> **NOTE**
> This function is deprecated because it supports only Portuguese month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Portuguese. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Dez 2016
- 02 dez 2016
- 2 Dez 16
- 2/12/2016
- 02/12/16
- 2-Dez-2016
- 2-12-16

Accepted month names:

- Portuguese
  - janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
  - jan fev mar abr mai jun jul ago set out nov dez

Func_eu_date2 (deprecated)

> **NOTE**
> This function is deprecated because it supports only Dutch month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Dutch. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Mei 2016

- 02 mei 2016
- 2 Mei 16
- 2/12/2016
- 02/12/16
- 2-Mei-2016
- 2-12-16

Accepted month names:

- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept out okt nov dec

Func_expiration_date

Func_expiration_date looks for dates that are in formats commonly used by credit and debit cards. This function will match dates in format of "month/year", "month-year", "[month name] year", and "[month abbreviation] year". The names or abbreviations of months aren't case-sensitive.

Examples:

- MM/YY -- for example, 01/11 or 1/11
- MM/YYYY -- for example, 01/2011 or 1/2011
- MM-YY -- for example, 01-22 or 1-11
- MM-YYYY -- for example, 01-2000 or 1-2000

The following formats support YY or YYYY:

- Month-YYYY -- for example Jan-2010 or january-2010 or Jan-10 or january-10
- Month YYYY -- for example, 'january 2010' or 'Jan 2010' or 'january 10' or 'Jan 10'
- MonthYYYY -- for example, 'january2010' or 'Jan2010' or 'january10' or 'Jan10'
- Month/YYYY -- for example, 'january/2010' or 'Jan/2010' or 'january/10' or 'Jan/10'

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan Feb Mar Apr May June July Aug Sept Oct Nov Dec

Func_us_address

Func_us_address looks for a U.S. state name or postal abbreviation followed by a valid zip code. The zip code must be one of the correct zip codes associated with the U.S. state name or abbreviation. The U.S. state name and zip code cannot be separated by punctuation or letters.

Examples:

- Washington 98052
- Washington 98052-9998
- WA 98052
- WA 98052-9998

Customize a built-in sensitive information type

11/2/2020 • 9 minutes to read • Edit Online

When looking for sensitive information in content, you need to describe that information in what's called a *rule*. Data loss prevention (DLP) includes rules for the most-common sensitive information types that you can use right away. To use these rules, you have to include them in a policy. You might find that you want to adjust these built-in rules to meet your organization's specific needs, and you can do that by creating a custom sensitive information type. This topic shows you how to customize the XML file that contains the existing rule collection to detect a wider range of potential credit-card information.

You can take this example and apply it to other built-in sensitive information types. For a list of default sensitive information types and XML definitions, see Sensitive information type entity definitions.

Export the XML file of the current rules

To export the XML, you need to connect to the Security and Compliance Center via Remote PowerShell..

1. In the PowerShell, type the following to display your organization's rules on screen. If you haven't created your own, you'll only see the default, built-in rules, labeled "Microsoft Rule Package."

   ```
   Get-DlpSensitiveInformationTypeRulePackage
   ```

2. Store your organization's rules in a variable by typing the following. Storing something in a variable makes it easily available later in a format that works for remote PowerShell commands.

   ```
   $ruleCollections = Get-DlpSensitiveInformationTypeRulePackage
   ```

3. Make a formatted XML file with all that data by typing the following. (`Set-content` is the part of the cmdlet that writes the XML to the file.)

   ```
   Set-Content -path C:\custompath\exportedRules.xml -Encoding Byte -Value
   $ruleCollections.SerializedClassificationRuleCollection
   ```

   IMPORTANT

   Make sure that you use the file location where your rule pack is actually stored. `C:\custompath\` is a placeholder.

Find the rule that you want to modify in the XML

The cmdlets above exported the entire *rule collection*, which includes the default rules we provide. Next you'll need to look specifically for the Credit Card Number rule that you want to modify.

1. Use a text editor to open the XML file that you exported in the previous section.
2. Scroll down to the `<Rules>` tag, which is the start of the section that contains the DLP rules. Because this XML file contains the information for the entire rule collection, it contains other information at the top that you need to scroll past to get to the rules.
3. Look for *Func_credit_card* to find the Credit Card Number rule definition. In the XML, rule names can't

contain spaces, so the spaces are usually replaced with underscores, and rule names are sometimes abbreviated. An example of this is the U.S. Social Security number rule, which is abbreviated *SSN*. The Credit Card Number rule XML should look like the following code sample.

```
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085"
       patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
       <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
```

Now that you have located the Credit Card Number rule definition in the XML, you can customize the rule's XML to meet your needs. For a refresher on the XML definitions, see the Term glossary at the end of this topic.

Modify the XML and create a new sensitive information type

First, you need to create a new sensitive information type because you can't directly modify the default rules. You can do a wide variety of things with custom sensitive information types, which are outlined in Create a custom sensitive information type in Security & Compliance Center PowerShell. For this example, we'll keep it simple and only remove corroborative evidence and add keywords to the Credit Card Number rule.

All XML rule definitions are built on the following general template. You need to copy and paste the Credit Card Number definition XML in the template, modify some values (notice the ". . ." placeholders in the following example), and then upload the modified XML as a new rule that can be used in policies.

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="https://schemas.microsoft.com/office/2011/mce">
  <RulePack id=". . .">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id=". . ." />
    <Details defaultLangCode=". . .">
      <LocalizedDetails langcode=" . . . ">
         <PublisherName>. . .</PublisherName>
         <Name>. . .</Name>
         <Description>. . .</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

 <Rules>
   <!-- Paste the Credit Card Number rule definition here.-->
      <LocalizedStrings>
         <Resource idRef=". . .">
           <Name default="true" langcode=" . . . ">. . .</Name>
           <Description default="true" langcode=". . ."> . . .</Description>
         </Resource>
      </LocalizedStrings>
   </Rules>
</RulePackage>
```

Now, you have something that looks similar to the following XML. Because rule packages and rules are identified by their unique GUIDs, you need to generate two GUIDs: one for the rule package and one to replace the GUID for the Credit Card Number rule. The GUID for the entity ID in the following code sample is the one for our built-in rule definition, which you need to replace with a new one. There are several ways to generate GUIDs, but you can do it easily in PowerShell by typing **[guid]::NewGuid()**.

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="https://schemas.microsoft.com/office/2011/mce">
  <RulePack id="8aac8390-e99f-4487-8d16-7f0cdee8defc">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id="8d34806e-cd65-4178-ba0e-5d7d712e5b66" />
    <Details defaultLangCode="en">
      <LocalizedDetails langcode="en">
        <PublisherName>Contoso Ltd.</PublisherName>
        <Name>Financial Information</Name>
        <Description>Modified versions of the Microsoft rule package</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

 <Rules>
    <Entity id="db80b3da-0056-436e-b0ca-1f4cf7080d1f"
       patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
      <LocalizedStrings>
         <Resource idRef="db80b3da-0056-436e-b0ca-1f4cf7080d1f">
<!-- This is the GUID for the preceding Credit Card Number entity because the following text is for that
Entity. -->
           <Name default="true" langcode="en-us">Modified Credit Card Number</Name>
           <Description default="true" langcode="en-us">Credit Card Number that looks for additional
keywords, and another version of Credit Card Number that doesn't require keywords (but has a lower
confidence level)</Description>
         </Resource>
      </LocalizedStrings>
   </Rules>
</RulePackage>
```

Remove the corroborative evidence requirement from a sensitive information type

Now that you have a new sensitive information type that you're able to upload to the Security & Compliance Center, the next step is to make the rule more specific. Modify the rule so that it only looks for a 16-digit number that passes the checksum but doesn't require additional (corroborative) evidence, like keywords. To do this, you need to remove the part of the XML that looks for corroborative evidence. Corroborative evidence is very helpful in reducing false positives. In this case there are usually certain keywords or an expiration date near the credit card number. If you remove that evidence, you should also adjust how confident you are that you found a credit card number by lowering the `confidenceLevel`, which is 85 in the example.

```
<Entity id="db80b3da-0056-436e-b0ca-1f4cf7080d1f" patternsProximity="300"
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
      </Pattern>
    </Entity>
```

Look for keywords that are specific to your organization

You might want to require corroborative evidence but want different or additional keywords, and perhaps you

want to change where to look for that evidence. You can adjust the `patternsProximity` to expand or shrink the window for corroborative evidence around the 16-digit number. To add your own keywords, you need to define a keyword list and reference it within your rule. The following XML adds the keywords "company card" and "Contoso card" so that any message that contains those phrases within 150 characters of a credit card number will be identified as a credit card number.

```
<Rules>
<! -- Modify the patternsProximity to be "150" rather than "300." -->
    <Entity id="db80b3da-0056-436e-b0ca-1f4cf7080d1f" patternsProximity="150" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
<!-- Add the following XML, which references the keywords at the end of the XML sample. -->
          <Match idRef="My_Additional_Keywords" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
<!-- Add the following XML, and update the information inside the <Term> tags with the keywords that you
want to detect. -->
    <Keyword id="My_Additional_Keywords">
      <Group matchStyle="word">
        <Term caseSensitive="false">company card</Term>
        <Term caseSensitive="false">Contoso card</Term>
      </Group>
    </Keyword>
```

Upload your rule

To upload your rule, you need to do the following.

1. Save it as an .xml file with Unicode encoding. This is important because the rule won't work if the file is saved with a different encoding.
2. Connect to the Security and Compliance Center via Remote PowerShell.
3. In the PowerShell, type the following.

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData (Get-Content -Path
   "C:\custompath\MyNewRulePack.xml" -Encoding Byte)
   ```

   IMPORTANT

   Make sure that you use the file location where your rule pack is actually stored. `C:\custompath\` is a placeholder.

4. To confirm, type Y, and then press **Enter**.
5. Verify that your new rule was uploaded and its display name by typing:

   ```
   Get-DlpSensitiveInformationType
   ```

To start using the new rule to detect sensitive information, you need to add the rule to a DLP policy. To learn how to add the rule to a policy, see Create a DLP policy from a template.

Term glossary

These are the definitions for the terms you encountered during this procedure.

TERM	DEFINITION
Entity	Entities are what we call sensitive information types, such as credit card numbers. Each entity has a unique GUID as its ID. If you copy a GUID and search for it in the XML, you'll find the XML rule definition and all the localized translations of that XML rule. You can also find this definition by locating the GUID for the translation and then searching for that GUID.
Functions	The XML file references `Func_credit_card`, which is a function in compiled code. Functions are used to run complex regexes and verify that checksums match for our built-in rules.) Because this happens in the code, some of the variables don't appear in the XML file.
IdMatch	This is the identifier that the pattern is to trying to match—for example, a credit card number.
Keyword lists	The XML file also references `keyword_cc_verification` and `keyword_cc_name`, which are lists of keywords from which we are looking for matches within the `patternsProximity` for the entity. These aren't currently displayed in the XML.
Pattern	The pattern contains the list of what the sensitive type is looking for. This includes keywords, regexes, and internal functions, which perform tasks like verifying checksums. Sensitive information types can have multiple patterns with unique confidences. This is useful when creating a sensitive information type that returns a high confidence if corroborative evidence is found and a lower confidence if little or no corroborative evidence is found.
Pattern confidenceLevel	This is the level of confidence that the DLP engine found a match. This level of confidence is associated with a match for the pattern if the pattern's requirements are met. This is the confidence measure you should consider when using Exchange mail flow rules (also known as transport rules).
patternsProximity	When we find what looks like a credit card number pattern, `patternsProximity` is the proximity around that number where we'll look for corroborative evidence.

TERM	DEFINITION
recommendedConfidence	This is the confidence level we recommend for this rule. The recommended confidence applies to entities and affinities. For entities, this number is never evaluated against the `confidenceLevel` for the pattern. It's merely a suggestion to help you choose a confidence level if you want to apply one. For affinities, the `confidenceLevel` of the pattern must be higher than the `recommendedConfidence` number for a mail flow rule action to be invoked. The `recommendedConfidence` is the default confidence level used in mail flow rules that invokes an action. If you want, you can manually change the mail flow rule to be invoked based off the pattern's confidence level, instead.

Create custom sensitive information types with Exact Data Match based classification

2/18/2021 • 22 minutes to read • Edit Online

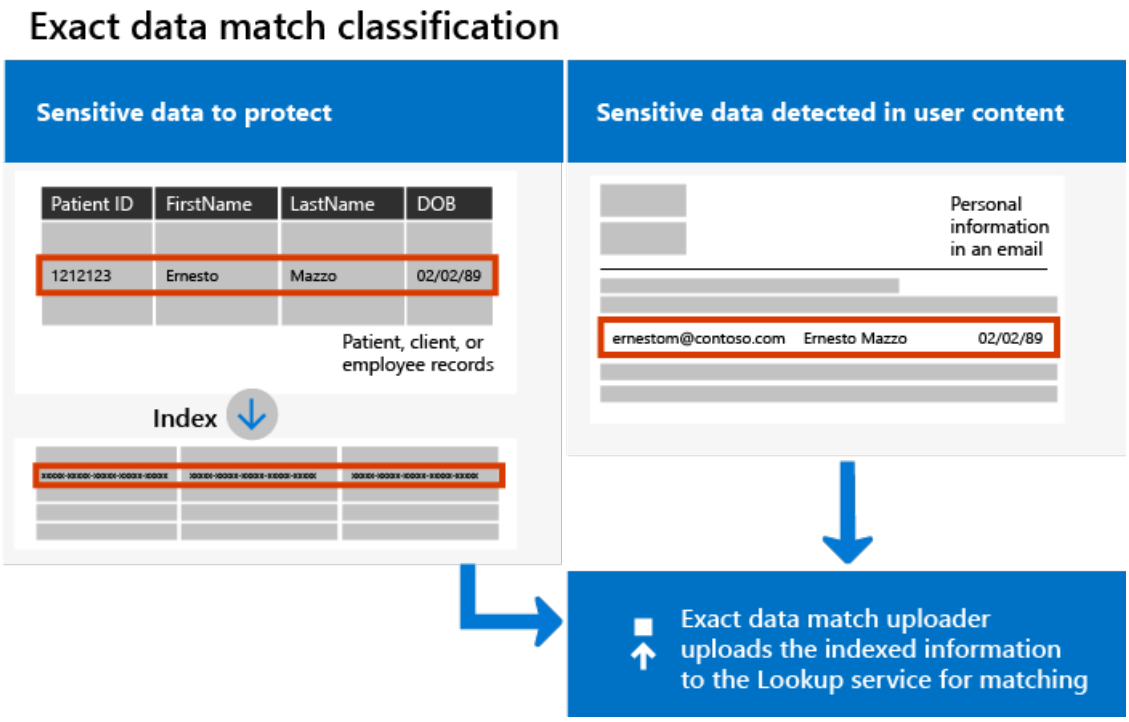
Custom sensitive information types are used to help identify sensitive items so that you can prevent them from being inadvertently or inappropriately shared. You define a custom sensitive information type based on:

- patterns
- keyword evidence such as *employee*, *badge*, or *ID*
- character proximity to evidence in a particular pattern
- confidence levels

Such custom sensitive information types meet business needs for many organizations.

But what if you wanted a custom sensitive information type that uses exact data values, instead of one that found matches based on generic patterns? With Exact Data Match (EDM)-based classification, you can create a custom sensitive information type that is designed to:

- be dynamic and easily refreshed
- be more scalable
- result in fewer false-positives
- work with structured sensitive data
- handle sensitive information more securely
- be used with several Microsoft cloud services



EDM-based classification enables you to create custom sensitive information types that refer to exact values in a database of sensitive information. The database can be refreshed daily, and contain up to 100 million rows of data. So as employees, patients, or clients come and go, and records change, your custom sensitive information types remain current and applicable. And, you can use EDM-based classification with policies, such as data loss prevention policies (DLP) or Microsoft Cloud App Security file policies.

NOTE

Microsoft 365 Information Protection now supports in preview double byte character set languages for:

- Chinese (simplified)
- Chinese (traditional)
- Korean
- Japanese

This support is available for sensitive information types. See, Information protection support for double byte character sets release notes (preview) for more information.

Required licenses and permissions

You must be a global admin, compliance administrator, or Exchange Online administrator to perform the tasks described in this article. To learn more about DLP permissions, see Permissions.

EDM-based classification is included in these subscriptions

- Office 365 E5
- Microsoft 365 E5
- Microsoft 365 E5 Compliance
- Microsoft E5/A5 Information Protection and Governance

Portal links for your subscription

PORTAL	WORLD WIDE/GCC	GCC-HIGH	DOD

Microsoft 365 Compliance center	compliance.microsoft.com	compliance.microsoft.us	compliance.apps.mil

The work flow at a glance

PHASE	WHAT'S NEEDED
Part 1: Set up EDM-based classification (As needed) - Edit the database schema - Remove the schema	- Read access to the sensitive data - Database schema in XML format (example provided) - Rule package in XML format (example provided) - Admin permissions to the Security & Compliance Center (using PowerShell)
Part 2: Hash and upload the sensitive data (As needed) Refresh the data	- Custom security group and user account - Local admin access to machine with EDM Upload Agent - Read access to the sensitive data - Process and schedule for refreshing the data
Part 3: Use EDM-based classification with your Microsoft cloud services	- Microsoft 365 subscription with DLP - EDM-based classification feature enabled

Part 1: Set up EDM-based classification

Setting up and configuring EDM-based classification involves:

1. Saving sensitive data in .csv format
2. Define your sensitive information database schema
3. Create a rule package

Save sensitive data in .csv format

1. Identify the sensitive information you want to use. Export the data to an app, such as Microsoft Excel, and save the file in .csv format. The data file can include a maximum of:

   - Up to 100 million rows of sensitive data
   - Up to 32 columns (fields) per data source
   - Up to 5 columns (fields) marked as searchable

2. Structure the sensitive data in the .csv file such that the first row includes the names of the fields used for EDM-based classification. In your .csv file, you might have field names, such as "ssn", "birthdate", "firstname", "lastname". The column header names can't include spaces or underscores. For example, the sample .csv file that we use in this article is named *PatientRecords.csv*, and its columns include *PatientID*, *MRN*, *LastName*, *FirstName*, *SSN*, and more.

3. Pay attention to the format of the sensitive data fields. In particular, fields that may contain commas in their content (e.g. a street address that contains the value "Seattle,WA") would be parsed as two separate fields when parsed by the EDM tool. In order to avoid this, you need to ensure such fields are surrounded by single or double quotes in the sensitive data table. If fields with commas in them may also contain spaces, you would need to create a custom Sensitive Information Type that matches the corresponding format (e.g. a multi-word string with commas and spaces in it) to ensure the string is correctly matched when the document is scanned.

Define the schema for your database of sensitive information

If for business or technical reasons, you prefer not to use PowerShell or command line to create your schema and EDM sensitive info type patter (rule package), you can use the Exact Data Match Schema and Sensitive Information Type Wizard to create them. When you are done creating the schema and EDM sensitive info type pattern, return to complete all the steps necessary to make your EDM based sensitive information type available for use.

> **NOTE**
> The Exact Data Match Schema and Sensitive Information Type Wizard is only available for the World Wide and GCC clouds only.

1. Define the schema for the database of sensitive information in XML format (similar to our example below). Name this schema file **edm.xml**, and configure it such that for each column in the database, there is a line that uses the syntax:

   `\<Field name="" searchable=""/\>`.

   - Use column names for *Field name* values.
   - Use *searchable="true"* for the fields that you want to be searchable up to a maximum of 5 fields. At least one field must be searchable.

   As an example, the following XML file defines the schema for a patient records database, with five fields specified as searchable: *PatientID*, *MRN*, *SSN*, *Phone*, and *DOB*.

   (You can copy, modify, and use our example.)

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
      <DataStore name="PatientRecords" description="Schema for patient records" version="1">
            <Field name="PatientID" searchable="true" caseInsensitive="true" ignoredDelimiters="-
,/,*,#,^" />
            <Field name="MRN" searchable="true" />
            <Field name="FirstName" />
            <Field name="LastName" />
            <Field name="SSN" searchable="true" />
            <Field name="Phone" searchable="true" />
            <Field name="DOB" searchable="true" />
            <Field name="Gender" />
            <Field name="Address" />
      </DataStore>
</EdmSchema>
```

Configurable match using the caseInsensitive and ignoredDelimiters fields

The above XML sample makes use of the `caseInsensitive` and the `ignoredDelimiters` fields.

When you include the ***caseInsensitive*** field set to the value of `true` in your schema definition, EDM will not exclude an item based on case differences for `PatientID` field. So EDM will see, `PatientID` **FOO-1234** and **fOo-1234** as being identical.

When you include the ***ignoredDelimiters*** field with supported characters, EDM will ignore those characters in the `PatientID`. So EDM will see, `PatientID` **FOO-1234** and `PatientID` **FOO#1234** as being identical. The `ignoredDelimiters` flag supports any non-alphanumeric character, here are some examples:

- .
- -
- /
- _
- *
- ^
- #
- !
- ?
- [
-]
- {
- }
- \
- ~
- ;
- The `ignoredDelimiters` flag doesn't support:
- characters 0-9
- A-Z

- a-z
- "
- ,

In this example, where both `caseInsensitive` and `ignoredDelimiters` are used, EDM would see **FOO-1234** and **fOo#1234** as identical and classify the item as a patient record sensitive information type.

4. Connect to the Security & Compliance center using the procedures in Connect to Security & Compliance Center PowerShell.

5. To upload the database schema, run the following cmdlets, one at a time:

   ```
   $edmSchemaXml=Get-Content .\\edm.xml -Encoding Byte -ReadCount 0
   New-DlpEdmSchema -FileData $edmSchemaXml -Confirm:$true
   ```

   You will be prompted to confirm, as follows:

   > Confirm
   >
   > Are you sure you want to perform this action?
   >
   > New EDM Schema for the data store 'patientrecords' will be imported.
   >
   > [Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):

> **TIP**
> If you want your changes to occur without confirmation, in Step 5, use this cmdlet instead: New-DlpEdmSchema -FileData $edmSchemaXml

> **NOTE**
> It can take between 10-60 minutes to update the EDMSchema with additions. The update must complete before you execute steps that use the additions.

Set up a rule package

1. Create a rule package in XML format (with Unicode encoding), similar to the following example. (You can copy, modify, and use our example.)

   When you set up your rule package, make sure to correctly reference your .csv file and **edm.xml** file. You can copy, modify, and use our example. In this sample xml the following fields needs to be customized to create your EDM sensitive type:

   - **RulePack id & ExactMatch id**: Use New-GUID to generate a GUID.
   - **Datastore**: This field specifies EDM lookup data store to be used. You provide a data source name of a configured EDM Schema.
   - **idMatch**: This field points to the primary element for EDM.
     - Matches: Specifies the field to be used in exact lookup. You provide a searchable field name in EDM Schema for the DataStore.
     - Classification: This field specifies the sensitive type match that triggers EDM lookup. You can provide the Name or GUID of an existing built-in or custom sensitive information type. Be

aware that any string that matches the sensitive information type provided will be hashed and compared to every entry in the sensitive information table. In order to avoid causing performance issues, if you use a custom sensitive information type as the Classification element in EDM, avoid using one that will match a large percentage of content (such as "any number" or "any five-letter word") by adding supporting keywords or including formatting in the definition of the custom classification sensitive information type.

- **Match:** This field points to additional evidence found in proximity of idMatch.
  - Matches: You provide any field name in EDM Schema for DataStore.
- **Resource:** This section specifies the name and description for sensitive type in multiple locales.
  - idRef: You provide GUID for ExactMatch ID.
  - Name & descriptions: customize as required.

```
<RulePackage xmlns="http://schemas.microsoft.com/office/2018/edm">
  <RulePack id="fd098e03-1796-41a5-8ab6-198c93c62b11">
    <Version build="0" major="2" minor="0" revision="0" />
    <Publisher id="eb553734-8306-44b4-9ad5-c388ad970528" />
    <Details defaultLangCode="en-us">
      <LocalizedDetails langcode="en-us">
        <PublisherName>IP DLP</PublisherName>
        <Name>Health Care EDM Rulepack</Name>
        <Description>This rule package contains the EDM sensitive type for health care sensitive
types.</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>
  <Rules>
    <ExactMatch id = "E1CC861E-3FE9-4A58-82DF-4BD259EAB371" patternsProximity = "300" dataStore
="PatientRecords" recommendedConfidence = "65" >
      <Pattern confidenceLevel="65">
        <idMatch matches = "SSN" classification = "U.S. Social Security Number (SSN)" />
      </Pattern>
      <Pattern confidenceLevel="75">
        <idMatch matches = "SSN" classification = "U.S. Social Security Number (SSN)" />
        <Any minMatches ="3" maxMatches ="6">
          <match matches="PatientID" />
          <match matches="MRN"/>
          <match matches="FirstName"/>
          <match matches="LastName"/>
          <match matches="Phone"/>
          <match matches="DOB"/>
        </Any>
      </Pattern>
    </ExactMatch>
    <LocalizedStrings>
      <Resource idRef="E1CC861E-3FE9-4A58-82DF-4BD259EAB371">
        <Name default="true" langcode="en-us">Patient SSN Exact Match.</Name>
        <Description default="true" langcode="en-us">EDM Sensitive type for detecting Patient SSN.
</Description>
      </Resource>
    </LocalizedStrings>
  </Rules>
</RulePackage>
```

2. Upload the rule package by running the following PowerShell cmdlets, one at a time:

```
$rulepack=Get-Content .\\rulepack.xml -Encoding Byte -ReadCount 0
New-DlpSensitiveInformationTypeRulePackage -FileData $rulepack
```

At this point, you have set up EDM-based classification. The next step is to hash the sensitive data, and then

upload the hashes for indexing.

Recall from the previous procedure that our PatientRecords schema defines five fields as searchable: *PatientID*, *MRN*, *SSN*, *Phone*, and *DOB*. Our example rule package includes those fields and references the database schema file (**edm.xml**), with one *ExactMatch* item per searchable field. Consider the following ExactMatch item:

```
<ExactMatch id = "E1CC861E-3FE9-4A58-82DF-4BD259EAB371" patternsProximity = "300" dataStore
="PatientRecords" recommendedConfidence = "65" >
      <Pattern confidenceLevel="65">
        <idMatch matches = "SSN" classification = "U.S. Social Security Number (SSN)" />
      </Pattern>
      <Pattern confidenceLevel="75">
        <idMatch matches = "SSN" classification = "U.S. Social Security Number (SSN)" />
        <Any minMatches ="3" maxMatches ="100">
          <match matches="PatientID" />
          <match matches="MRN"/>
          <match matches="FirstName"/>
          <match matches="LastName"/>
          <match matches="Phone"/>
          <match matches="DOB"/>
        </Any>
      </Pattern>
    </ExactMatch>
```

In this example, note that:

- The dataStore name references the .csv file we created earlier: **dataStore = "PatientRecords"**.
- The idMatch value references a searchable field that is listed in the database schema file: **idMatch matches = "SSN"**.
- The classification value references an existing or custom sensitive information type: **classification = "U.S. Social Security Number (SSN)"**. (In this case, we use the existing sensitive information type of U.S. Social Security Number.)

> **NOTE**
> It can take between 10-60 minutes to update the EDMSchema with additions. The update must complete before you execute steps that use the additions.

Editing the schema for EDM-based classification

If you want to make changes to your **edm.xml** file, such as changing which fields are used for EDM-based classification, follow these steps:

> **TIP**
> You can change your EDM schema and data file to take advantage of **configurable match**. When configured, EDM will ignore case differences and some delimiters when it evaluates an item. This makes defining your xml schema and your sensitive data files easier. To learn more see, Modify Exact Data Match schema to use configurable match.

1. Edit your **edm.xml** file (this is the file discussed in the Define the schema section of this article).
2. Connect to the Security & Compliance center using the procedures in Connect to Security & Compliance Center PowerShell.
3. To update your database schema, run the following cmdlets, one at a time:

```
$edmSchemaXml=Get-Content .\\edm.xml -Encoding Byte -ReadCount 0
Set-DlpEdmSchema -FileData $edmSchemaXml -Confirm:$true
```

You will be prompted to confirm, as follows:

> Confirm
>
> Are you sure you want to perform this action?
>
> EDM Schema for the data store 'patientrecords' will be updated.
>
> [Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):

> **TIP**
> If you want your changes to occur without confirmation, in Step 3, use this cmdlet instead: Set-DlpEdmSchema -FileData $edmSchemaXml

> **NOTE**
> It can take between 10-60 minutes to update the EDMSchema with additions. The update must complete before you execute steps that use the additions.

Removing the schema for EDM-based classification

(As needed) If you want to remove the schema you're using for EDM-based classification, follow these steps:

1. Connect to the Security & Compliance center using the procedures in Connect to Security & Compliance Center PowerShell.
2. Run the following PowerShell cmdlets, substituting the data store name of "patient records" with the one you want to remove:

```
Remove-DlpEdmSchema -Identity patientrecords
```

You will be prompted to confirm:

> Confirm
>
> Are you sure you want to perform this action?
>
> EDM Schema for the data store 'patientrecords' will be removed.
>
> [Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):

> **TIP**
> If you want your changes to occur without confirmation, in Step 2, use this cmdlet instead: Remove-DlpEdmSchema -Identity patientrecords -Confirm:$false

Part 2: Hash and upload the sensitive data

In this phase, you set up a custom security group and user account, and set up the EDM Upload Agent tool. Then, you use the tool to hash with salt value the sensitive data, and upload it.

The hashing and uploading can be done using one computer or you can separate the hashing step from the upload step for greater security.

If you want to hash and upload from one computer, you need to do it from a computer that can directly connect to your Microsoft 365 tenant. This requires that your clear text sensitive data files are on that computer for hashing.

If you do not want to expose your clear text sensitive data file, you can hash it on a computer in a secure location and then copy the hash file and the salt file to a computer that can directly connect to your Microsoft 365 tenant for upload. In this scenario, you will need the EDMUploadAgent on both computers.

> **IMPORTANT**
> If you used the Exact Data Match schema and sensitive information type wizard to create your schema and pattern files, you ***must** download the schema for this procedure.

Prerequisites

- a work or school account for Microsoft 365 that will be added to the **EDM_DataUploaders** security group
- a Windows 10 or Windows Server 2016 machine with .NET version 4.6.2 for running the EDMUploadAgent
- a directory on your upload machine for the:
  - EDMUploadAgent
  - your sensitive item file in csv format **PatientRecords.csv** in our examples
  - and the output hash and salt files
  - the datastore name from the **edm.xml** file, for this example its `PatientRecords`
- If you used the Exact Data Match schema and sensitive information type wizard you ***must*** download it

Set up the security group and user account

1. As a global administrator, go to the admin center using the appropriate link for your subscription and create a security group called **EDM_DataUploaders**.
2. Add one or more users to the **EDM_DataUploaders** security group. (These users will manage the database of sensitive information.)

Hash and upload from one computer

This computer must have direct access to your Microsoft 365 tenant.

> **NOTE**
> Before you begin this procedure, make sure that you are a member of the **EDM_DataUploaders** security group.

> **TIP**
> Optionally, you can run a validation against your csv file before uploading by running:
>
> `EdmUploadAgent.exe /ValidateData /DataFile [data file] /Schema [schema file]`
>
> For more information on all the EdmUploadAgent.exe >supported parameters run
>
> `EdmUploadAgent.exe /?`

Links to EDM upload agent by subscription type

- Commercial + GCC - most commercial customers should use this
- GCC-High - This is specifically for high security government cloud subscribers
- DoD - this is specifically for United States Department of Defense cloud customers

1. Create a working directory for the EDMUploadAgent. For example, **C:\EDM\Data**. Place the **PatientRecords.csv** file there.

2. Download and install the appropriate EDM Upload Agent for your subscription into the directory you created in step 1.

   > **NOTE**
   >
   > The EDMUploadAgent at the above links has been updated to automatically add a salt value to the hashed data. Alternately, you can provide your own salt value. Once you have used this version, you will not be able to use the previous version of the EDMUploadAgent.
   >
   > You can upload data with the EDMUploadAgent to any given data store only twice per day.

   > **TIP**
   >
   > To a get a list out of the supported command parameters, run the agent no arguments. For example 'EdmUploadAgent.exe'.

3. Authorize the EDM Upload Agent, open Command Prompt window (as an administrator), switch to the **C:\EDM\Data** directory and then run the following command:

   ```
   EdmUploadAgent.exe /Authorize
   ```

4. Sign in with your work or school account for Microsoft 365 that was added to the EDM_DataUploaders security group. Your tenant information is extracted from the user account to make the connection.

   OPTIONAL: If you used the Exact Data Match schema and sensitive information type wizard to create your schema and pattern files, run the following command in a Command Prompt window:

   ```
   EdmUploadAgent.exe /SaveSchema /DataStoreName <schema name> /OutputDir <path to output folder>
   ```

5. To hash and upload the sensitive data, run the following command in Command Prompt window:

   ```
   EdmUploadAgent.exe /UploadData /DataStoreName [DS Name] /DataFile [data file] /HashLocation [hash file location] /Schema [Schema file]
   ```

   Example: **EdmUploadAgent.exe /UploadData /DataStoreName PatientRecords /DataFile C:\Edm\Hash\PatientRecords.csv /HashLocation C:\Edm\Hash /Schema edm.xml**

   This will automatically add a randomly generated salt value to the hash for greater security. Optionally, if you want to use your own salt value, add the **/Salt** to the command. This value must be 64 characters in length and can only contain the a-z characters and 0-9 characters.

6. Check the upload status by running this command:

   ```
   EdmUploadAgent.exe /GetSession /DataStoreName \<DataStoreName\>
   ```

   Example: **EdmUploadAgent.exe /GetSession /DataStoreName PatientRecords**

   Look for the status to be in **ProcessingInProgress**. Check again every few minutes until the status changes to **Completed**. Once the status is completed, your EDM data is ready for use.

Separate Hash and upload

Perform the hash on a computer in a secure environment.

OPTIONAL: If you used the Exact Data Match schema and sensitive information type wizard to create your schema and pattern files, run the following command in a Command Prompt window:

```
EdmUploadAgent.exe /SaveSchema /DataStoreName <schema name> /OutputDir <path to output folder>
```

1. Run the following command in Command Prompt windows:

   ```
   EdmUploadAgent.exe /CreateHash /DataFile [data file] /HashLocation [hash file location] /Schema
   [Schema file] >
   ```

   For example:

   > **EdmUploadAgent.exe /CreateHash /DataFile C:\Edm\Data\PatientRecords.csv /HashLocation C:\Edm\Hash /Schema edm.xml**

   This will output a hashed file and a salt file with these extensions if you didn't specify the **/Salt** option:

   - .EdmHash
   - .EdmSalt

2. Copy these files in a secure fashion to the computer you will use to upload your sensitive items csv file (PatientRecords) to your tenant.

   To upload the hashed data, run the following command in Windows Command Prompt:

   ```
   EdmUploadAgent.exe /UploadHash /DataStoreName \<DataStoreName\> /HashFile \<HashedSourceFilePath\>
   ```

   For example:

   > **EdmUploadAgent.exe /UploadHash /DataStoreName PatientRecords /HashFile C:\Edm\Hash\PatientRecords.EdmHash**

   To verify that your sensitive data has been uploaded, run the following command in Command Prompt window:

   ```
   EdmUploadAgent.exe /GetDataStore
   ```

   You'll see a list of data stores and when they were last updated.

   If you want to see all the data uploads to a particular store, run the following command in a Windows command prompt:

   ```
   EdmUploadAgent.exe /GetSession /DataStoreName <DataStoreName>
   ```

   Proceed to set up your process and schedule for Refreshing your sensitive information database.

At this point, you are ready to use EDM-based classification with your Microsoft cloud services. For example, you can set up a DLP policy using EDM-based classification.

Refreshing your sensitive information database

You can refresh your sensitive information database daily, and the EDM Upload Tool can reindex the sensitive data and then reupload the indexed data.

1. Determine your process and frequency (daily or weekly) for refreshing the database of sensitive information.

2. Re-export the sensitive data to an app, such as Microsoft Excel, and save the file in .csv format. Keep the same file name and location you used when you followed the steps described in Hash and upload the sensitive data.

> **NOTE**
>
> If there are no changes to the structure (field names) of the .csv file, you won't need to make any changes to your database schema file when you refresh the data. But if you must make changes, make sure to edit the database schema and your rule package accordingly.

3. Use Task Scheduler to automate steps 2 and 3 in the Hash and upload the sensitive data procedure. You can schedule tasks using several methods:

METHOD	WHAT TO DO
Windows PowerShell	See the ScheduledTasks documentation and the example PowerShell script in this article
Task Scheduler API	See the Task Scheduler documentation
Windows user interface	In Windows, click **Start**, and type Task Scheduler. Then, in the list of results, right-click **Task Scheduler**, and choose **Run as administrator**.

Example PowerShell script for Task Scheduler

This section includes an example PowerShell script you can use to schedule your tasks for hashing data and uploading the hashed data:

To schedule hashing and upload in a combined step

```
param(\[string\]$dataStoreName,\[string\]$fileLocation)
\# Assuming current user is also the user context to run the task
$user = "$env:USERDOMAIN\\$env:USERNAME"
$edminstallpath = 'C:\\Program Files\\Microsoft\\EdmUploadAgent\\'
$edmuploader = $edminstallpath + 'EdmUploadAgent.exe'
$csvext = '.csv'
$schemaext = '.xml'
\# Assuming CSV file name is same as data store name
$dataFile = "$fileLocation\\$dataStoreName$csvext"
\# Assuming location to store hash file is same as the location of csv file
$hashLocation = $fileLocation
\# Assuming Schema file name is same as data store name
$schemaFile = "$fileLocation\\$dataStoreName$schemaext"
$uploadDataArgs = '/UploadData /DataStoreName ' + $dataStoreName + ' /DataFile ' + $dataFile + '
/HashLocation' + $hashLocation + ' /Schema ' + $schemaFile
\# Set up actions associated with the task
$actions = @()
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $uploadDataArgs -WorkingDirectory
$edminstallpath
\# Set up trigger for the task
$trigger = New-ScheduledTaskTrigger -Weekly -DaysOfWeek Sunday -At 2am
\# Set up task settings
$principal = New-ScheduledTaskPrincipal -UserId $user -LogonType S4U -RunLevel Highest
$settings = New-ScheduledTaskSettingsSet -RunOnlyIfNetworkAvailable -StartWhenAvailable -WakeToRun
\# Create the scheduled task
$scheduledTask = New-ScheduledTask -Action $actions -Principal $principal -Trigger $trigger -Settings
$settings
\# Get credentials to run the task
$creds = Get-Credential -UserName $user -Message "Enter credentials to run the task"
$password=\[Runtime.InteropServices.Marshal\]::PtrToStringAuto(\
[Runtime.InteropServices.Marshal\]::SecureStringToBSTR($creds.Password))
\# Register the scheduled task
$taskName = 'EDMUpload\_' + $dataStoreName
Register-ScheduledTask -TaskName $taskName -InputObject $scheduledTask -User $user -Password $password
```

To schedule hashing and upload as separate steps

```
param(\[string\]$dataStoreName,\[string\]$fileLocation)
\# Assuming current user is also the user context to run the task
$user = "$env:USERDOMAIN\\$env:USERNAME"
$edminstallpath = 'C:\\Program Files\\Microsoft\\EdmUploadAgent\\'
$edmuploader = $edminstallpath + 'EdmUploadAgent.exe'
$csvext = '.csv'
$edmext = '.EdmHash'
$schemaext = '.xml'
\# Assuming CSV file name is same as data store name
$dataFile = "$fileLocation\\$dataStoreName$csvext"
$hashFile = "$fileLocation\\$dataStoreName$edmext"
\# Assuming Schema file name is same as data store name
$schemaFile = "$fileLocation\\$dataStoreName$schemaext "

\# Assuming location to store hash file is same as the location of csv file
$hashLocation = $fileLocation
$createHashArgs = '/CreateHash' + ' /DataFile ' + $dataFile + ' /HashLocation ' + $hashLocation + ' /Schema
' + $schemaFile
$uploadHashArgs = '/UploadHash /DataStoreName ' + $dataStoreName + ' /HashFile ' + $hashFile
\# Set up actions associated with the task
$actions = @()
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $createHashArgs -WorkingDirectory
$edminstallpath
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $uploadHashArgs -WorkingDirectory
$edminstallpath
\# Set up trigger for the task
$trigger = New-ScheduledTaskTrigger -Weekly -DaysOfWeek Sunday -At 2am
\# Set up task settings
$principal = New-ScheduledTaskPrincipal -UserId $user -LogonType S4U -RunLevel Highest
$settings = New-ScheduledTaskSettingsSet -RunOnlyIfNetworkAvailable -StartWhenAvailable -WakeToRun
\# Create the scheduled task
$scheduledTask = New-ScheduledTask -Action $actions -Principal $principal -Trigger $trigger -Settings
$settings
\# Get credentials to run the task
$creds = Get-Credential -UserName $user -Message "Enter credentials to run the task"
$password=\[Runtime.InteropServices.Marshal\]::PtrToStringAuto(\
[Runtime.InteropServices.Marshal\]::SecureStringToBSTR($creds.Password))
\# Register the scheduled task
$taskName = 'EDMUpload\_' + $dataStoreName
Register-ScheduledTask -TaskName $taskName -InputObject $scheduledTask -User $user -Password $password
```

Part 3: Use EDM-based classification with your Microsoft cloud services

These locations are support EDM sensitive information types:

- DLP for Exchange Online (email)
- OneDrive for Business (files)
- Microsoft Teams (conversations)
- DLP for SharePoint (files)
- Microsoft Cloud App Security DLP policies

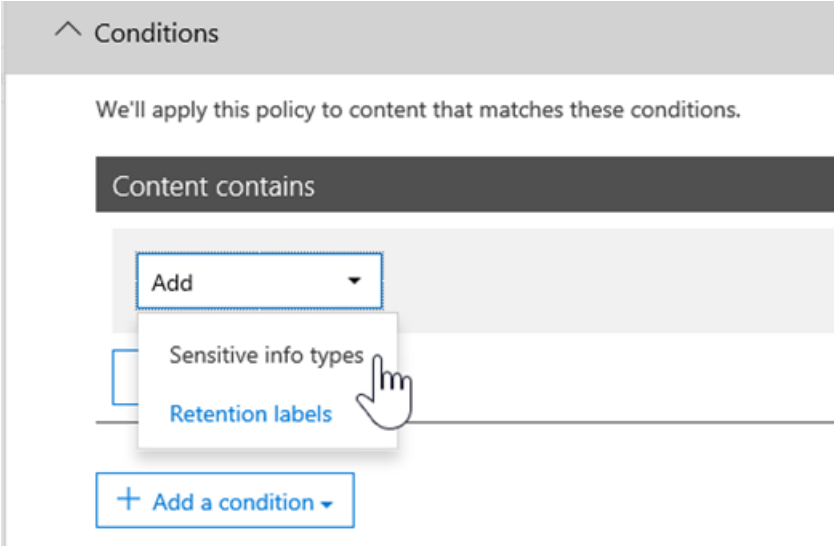
EDM sensitive information types for following scenarios are currently in development, but not yet available:

- Auto-classification of sensitivity labels and retention labels

To create a DLP policy with EDM

1. Go to the Security & Compliance Center using the appropriate link for your subscription.
2. Choose **Data loss prevention** > **Policy**.
3. Choose **Create a policy** > **Custom** > **Next**.

4. On the **Name your policy** tab, specify a name and description, and then choose **Next**.
5. On the **Choose locations** tab, select **Let me choose specific locations**, and then choose **Next**.
6. In the **Status** column, select **Exchange email, OneDrive accounts, Teams chat and channel message**, and then choose **Next**.
7. On the **Policy settings** tab, choose **Use advanced settings**, and then choose **Next**.
8. Choose **+ New rule**.
9. In the **Name** section, specify a name and description for the rule.
10. In the **Conditions** section, in the **+ Add a condition** list, choose **Content contains sensitive type**.



11. Search for the sensitive information type you created when you set up your rule package, and then choose **+ Add**.
    Then choose **Done**.
12. Finish selecting options for your rule, such as **User notifications**, **User overrides**, **Incident reports**, and so on, and then choose **Save**.
13. On the **Policy settings** tab, review your rules, and then choose **Next**.
14. Specify whether to turn on the policy right away, test it out, or keep it turned off. Then choose **Next**.
15. On the **Review your settings** tab, review your policy. Make any needed changes. When you're ready, choose **Create**.

> **NOTE**
> Allow approximately one hour for your new DLP policy to work its way through your data center.

Use the Exact Data Match Schema and Sensitive Information Type Wizard

2/18/2021 • 2 minutes to read • Edit Online

Creating a custom sensitive information type with Exact Data Match (EDM) based classification involves many steps. You can use this wizard to create your schema and sensitive information type pattern (rule package) files to help simplify the process.

> **NOTE**
> The Exact Data Match Schema and Sensitive Information Type Wizard is only available for the World Wide and GCC clouds only.

This wizard can be used instead of the:

- Define the schema for your database of sensitive information
- Set up a pattern (rule package)

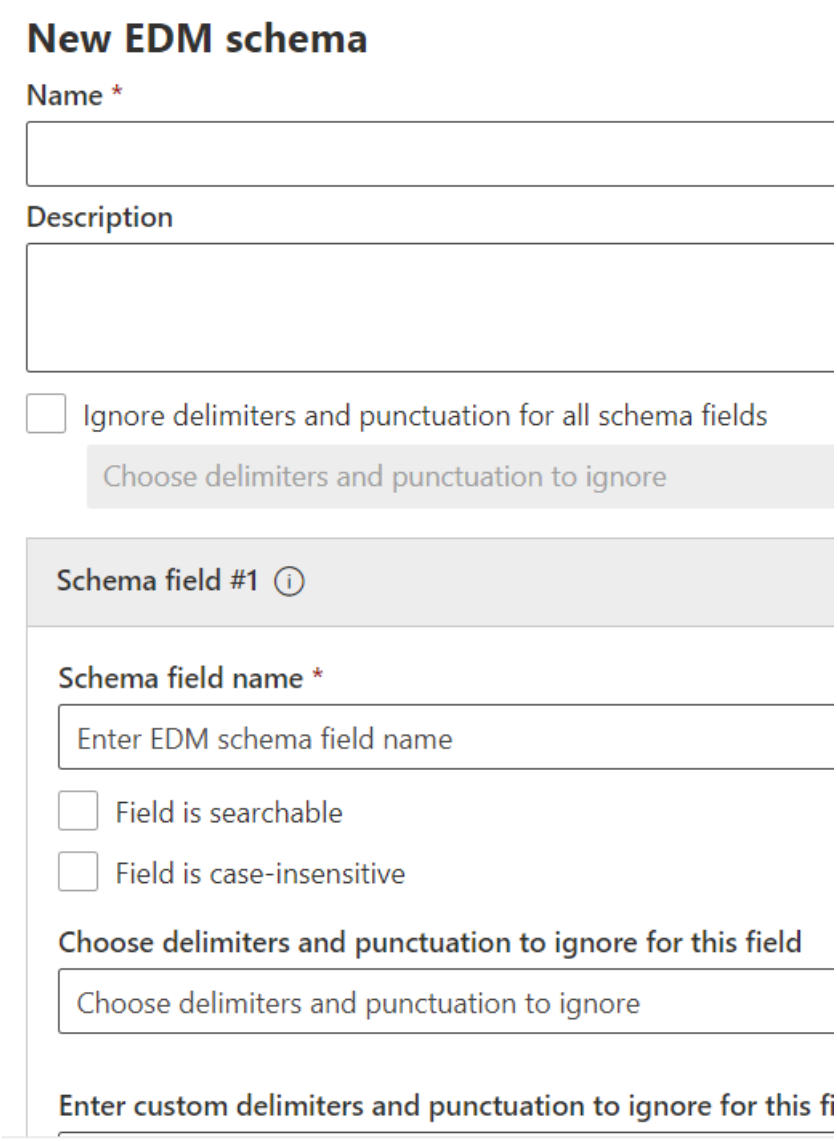
steps in Part 1: Set up EDM-based classification.

Pre-requisites

1. Familiarize yourself with the steps to create a custom sensitive information type with EDM work flow at a glance.
2. Perform the steps in the Save sensitive data in .csv format section.

Use the exact data match schema and sensitive information type pattern wizard

1. In the Microsoft 365 Compliance center for your tenant go to **Data classification** > **Exact data matches**.
2. Choose **Create EDM schema** to open the schema wizard configuration flyout.



3. Fill in an appropriate **Name** and **Description**.
4. Choose **Ignore delimiters and punctuations for all schema fields** if you want that behavior. To learn more about configuring EDM to ignore case or delimitere, see Creating a custom sensitive information type with Exact Data Match (EDM) based classification.
5. Fill in your desired values for your **Schema field #1** and add more fields as needed.

> **IMPORTANT**
> At least one, but no more than five of your schema fields must be designated as searchable.

6. Choose save. Your schema will now be listed.
7. Choose **EDM sensitive info types** and **Create EDM sensitive info type** to open the sensitive info type configuration wizard.
8. Choose **Choose an existing EDM schema** and choose the schema you created in steps 2-6 from the list.
9. Choose **Next** and choose **Create pattern**.
10. Choose the **Confidence level** and **Primary element**. To learn more about configuring a pattern, see Create a custom sensitive information type in the Compliance Center

11. Choose the **Primary element's sensitive info type** to associate it with. See Sensitive Information Type Entity Definitions to learn more about the available sensitive information types.
12. Choose **Done**.
13. Choose your desired **Confidence level and character proximity**. This will be the default value for the whole EDM sensitive info type
14. Choose **Create pattern** if you want to creaet additional patterns for your EDM sensitive info type.
15. Choose **Next** and fill in a **Name** and **Description for admins**.
16. Review and choose **Submit**.

You can delete or edit the sensitive information type pattern by selecting it which surfaces the edit and delete controls.

> **IMPORTANT**
> If you want to remove a schema, and it is already associated with an EDM sensitive info type, you must first delete the EDM sensitive info type, then you can delete the schema.

Post steps

After you have used this wizard to create your EDM schema and pattern (rule package) files, you still have to perform the steps in Part 2: Hash and upload the sensitive data before you can use the EDM custom sensitive information type.

Modify Exact Data Match schema to use configurable match

2/18/2021 • 2 minutes to read • Edit Online

Exact Data Match (EDM) based classification enables you to create custom sensitive information types that refer to exact values in a database of sensitive information. When you need to allow for variants of a exact string, you can use *configurable match* to tell Microsoft 365 to ignore case and some delimiters.

> **IMPORTANT**
> Use this procedure to modify an existing EDM schema and data file.

1. Uninstall the **EdmUploadAgent.exe** from the computer that you use to connect to Microsoft 365 for EDM schema and data file upload purposes.
2. Download the appropriate **EdmUploadAgent.exe** file for your subscription using the links below:
   - Commercial + GCC - most commercial customers should use this
   - GCC-High - This is specifically for high security government cloud subscribers
   - DoD - this is specifically for United States Department of Defense cloud customers
3. Authorize the EDM Upload Agent, open Command Prompt window (as an administrator) and run the following command:

   ```
   EdmUploadAgent.exe /Authorize
   ```

4. If you don't have a current copy of the existing schema, you'll need to download a copy of the existing schema, run this command:

   ```
   EdmUploadAgent.exe /SaveSchema /DataStoreName <dataStoreName> [/OutputDir [Output dir location]]
   ```

5. Customize the schema so each column utilizes “caseInsensitive” and / or “ignoredDelimiters”. The default value for “caseInsensitive” is “false” and for “ignoredDelimiters”, it is an empty string.

> **NOTE**
> The underlying custom sensitive information type or built in sensitive information type used to detect the general regex pattern must support detection of the variations inputs listed with ignoredDelimiters. For example, the built in U.S. social security number (SSN) sensitive information type can detect variations in the data that include dashes, spaces, or lack of spaces between the grouped numbers that make up the SSN. As a result, the only delimiters that are relevant to include in EDM’s ignoredDelimiters for SSN data are: dash and space.

Here is a sample schema that simulates case insensitive match by creating the extra columns needed to recognize case variations in the sensitive data.

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
  <DataStore name="PatientRecords" description="Schema for patient records policy" version="1">
           <Field name="PolicyNumber" searchable="true" />
           <Field name="PolicyNumberLowerCase" searchable="true" />
           <Field name="PolicyNumberUpperCase" searchable="true" />
           <Field name="PolicyNumberCapitalLetters" searchable="true" />
  </DataStore>
</EdmSchema>
```

In the above example, the variations of the original `PolicyNumber` column will no longer be needed if both `caseInsensitive` and `ignoredDelimiters` are added.

To update this schema so that EDM uses configurable match use the `caseInsensitive` and `ignoredDelimiters` flags. Here's how that looks:

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
  <DataStore name="PatientRecords" description="Schema for patient records policy" version="1">
         <Field name="PolicyNumber" searchable="true" caseInsensitive="true" ignoredDelimiters="-,/,*,#,^"
/>
  </DataStore>
</EdmSchema>
```

The `ignoredDelimiters` flag supports any non-alphanumeric character, here are some examples:

- .
- -
- /
- _
- *
- ^
- #
- !
- ?
- [
-]
- {
- }
- \
- ~
- ;

The `ignoredDelimiters` flag doesn't support:

- characters 0-9
- A-Z
- a-z
- "
- ,

6. Connect to the Security & Compliance center using the procedures in Connect to Security & Compliance Center PowerShell.

7. Update your schema by running these cmdlets one at a time:

```
$edmSchemaXml=Get-Content .\\edm.xml -Encoding Byte -ReadCount 0
```

```
Set-DlpEdmSchema -FileData $edmSchemaXml -Confirm:$true
```

8. If necessary, update the data file to match the new schema version

> **TIP**
>
> Optionally, you can run a validation against your csv file before uploading by running:
>
> ```
> EdmUploadAgent.exe /ValidateData /DataFile [data file] [schema file]
> ```
>
> For more information on all the EdmUploadAgent.exe >supported parameters run
>
> ```
> EdmUploadAgent.exe /?
> ```

9. Open Command Prompt window (as an administrator) and run the following command to hash and upload your sensitive data:

   ```
   EdmUploadAgent.exe /UploadData /DataStoreName [DS Name] /DataFile [data file] /HashLocation [hash file location] /Salt [custom salt] /Schema [Schema file]
   ```

Get started with custom sensitive information types

2/18/2021 • 5 minutes to read • Edit Online

If the pre-configured sensitive information types don't meet your needs, you can create your own custom sensitive information types that you fully define or you can copy one of the pre-configured ones and modify it.

The custom sensitive information types that you create by using this method are added to the rule package named `Microsoft.SCCManaged.CustomRulePack`.

There are two ways to create a new sensitive information type:

- from scratch where you fully define all elements
- copy and modify an existing sensitive information type

Before you begin

- You should be familiar with sensitive information types and what they are composed of. See, Learn about sensitive information types. It is critical to understand the roles of:
  - regular expressions - Microsoft 365 sensitive information types uses the Boost.RegEx 5.1.3 engine
  - keyword lists - you can create your own as you define your sensitive information type or choose from existing keyword lists
  - keyword dictionary
  - functions
  - confidence levels
- You must have Global admin or Compliance admin permissions to create, test, and deploy a custom sensitive information type through the UI. See About admin roles in Office 365.
- Your organization must have a subscription, such as Office 365 Enterprise, that includes Data Loss Prevention (DLP). See Messaging Policy and Compliance ServiceDescription.

> **IMPORTANT**
> Microsoft Customer Service & Support can't assist with creating custom classifications or regular expression patterns. Support engineers can provide limited support for the feature, such as, providing sample regular expression patterns for testing purposes, or assisting with troubleshooting an existing regular expression pattern that's not triggering as expected, but can't provide assurances that any custom content-matching development will fulfill your requirements or obligations.

Create a custom sensitive information type

Use this procedure to create a new sensitive information type that you fully define.

1. In the Compliance Center, go to **Data classification** > **Sensitive info types** and choose **Create info type**.
2. Fill in values for **Name** and **Description** and choose **Next**.
3. Choose **Create pattern**. You can create multiple patterns, each with different elements and confidence levels, as you define your new sensitive information type.
4. Choose the default confidence level for the pattern. The values are **Low confidence**, **Medium confidence**, and **High confidence**.
5. Choose and define **Primary element**. The primary element can be a **Regular expression** with an optional

validator, a **Keyword list**, a **Keyword dictionary**, or one of the pre-configured **Functions**. For more information on DLP functions, see What the DLP functions look for.

6. Fill in a value for **Character proximity**.
7. (Optional) Add supporting elements if you have any. Supporting elements can be a regular expression with an optional validator, a keyword list, a keyword dictionary or one of the pre-defined functions.
8. (Optional) Add additional checks from the list of available checks
9. Choose **Create**.
10. Choose **Next**.
11. Choose the **recommended confidence level** for this sensitive information type.
12. Check your setting and choose **Submit**.

> **IMPORTANT**
> Microsoft 365 uses the search crawler to identify and classify sensitive information in SharePoint Online and OneDrive for Business sites. To identify your new custom sensitive information type in existing content, the content must be re-crawled. Content is crawled based on a schedule, but you can manually re-crawl content for a site collection, list, or library. For more information, see Manually request crawling and re-indexing of a site, a library or a list.

13. On the **Data classification** page, you'll see all the sensitive information types listed. Choose **Refresh** and then browse for or use the search tool to find the sensitive information type you just created.

Test a sensitive information type

You can test any sensitive information type in the list. We suggest that you test every sensitive information type that you create before using it in a policy.

1. Prepare two files, like a Word document. One with content that matches the elements you specified in your sensitive information type and one that doesn't match.
2. In the Compliance Center, go to **Data classification** > **Sensitive info types** and choose the sensitive information type from the list to open the details pane and choose **Test**.
3. Upload a file and choose **Test**.
4. On the **Matches results** page, review the results and choose **Finish**.

Modify custom sensitive information types in the Compliance Center

1. In the Compliance Center, go to **Data classification** > **Sensitive info types** and choose the sensitive information type from the list that you want to modify choose **Edit**.
2. You can add other patterns, with unique primary and supporting elements, confidence levels, character proximity, and additional checks or edit/remove the existing ones. For more information, see Create a custom sensitive information type.

Remove custom sensitive information types in the Compliance Center

> **NOTE**
> You can only remove custom sensitive information types; you can't remove built-in sensitive information types.

IMPORTANT

Before your remove a custom sensitive information type, verify that no DLP policies or Exchange mail flow rules (also known as transport rules) still reference the sensitive information type.

1. In the Compliance Center, go to **Data classification** > **Sensitive info types** and choose the sensitive information type from the list that you want to remove.
2. In the fly-out that opens, choose **Delete**.

Copy and modify a sensitive information type

Use this procedure to create a new sensitive information type that is based on an existing sensitive information type.

1. In the Compliance Center, go to **Data classification** > **Sensitive info types** and choose the sensitive information type that you want to copy.
2. In the flyout, choose **Copy**.
3. Choose **Refresh** in the list of sensitive information types and either browse or search for the copy you just made. Partial sting searches work, so you could just search for `copy` and search would return all the sensitive information types with the word `copy` in the name.
4. Fill in values for **Name** and **Description** and choose **Next**.
5. Choose your sensitive information type copy and choose **Edit**.
6. Give your new sensitive information type a new **Name** and **Description**.
7. You can choose to edit or remove the existing patterns and add new ones. Choose the default confidence level for the new pattern. The values are **Low confidence**, **Medium confidence**, and **High confidence**.
8. Choose and define **Primary element**. The primary element can be a **Regular expression**, a **Keyword list**, a **Keyword dictionary**, or one of the pre-configured **Functions**. See, What the DLP functions look for.
9. Fill in a value for **Character proximity**.
10. (Optional) If you have **Supporting elements** or any **Additional checks** add them. If needed you can group your **Supporting elements**.
11. Choose **Create**.
12. Choose **Next**.
13. Choose the **recommended confidence level** for this sensitive information type.
14. Check your setting and choose **Submit**.

You can also create custom sensitive information types by using PowerShell and Exact Data Match capabilities. To learn more about those methods, see:

- Create a custom sensitive information type in Security & Compliance Center PowerShell
- Create a custom sensitive information type for DLP with Exact Data Match (EDM)

NOTE

Microsoft 365 Information Protection supports, in preview, double byte character set languages for:

- Chinese (simplified)
- Chinese (traditional)
- Korean
- Japanese

This support is available for sensitive information types. See, Information protection support for double byte character sets release notes (preview) for more information.

Create a custom sensitive information type using PowerShell

2/18/2021 • 27 minutes to read • Edit Online

This topic shows you how to use PowerShell to create an XML *rule package* file that defines your own custom sensitive information types. You need to know how to create a regular expression. As an example, this topic creates a custom sensitive information type that identifies an employee ID. You can use this example XML as a starting point for your own XML file. If you are new to sensitive information types, see Learn about sensitive information types.

After you've created a well-formed XML file, you can upload it to Microsoft 365 by using Microsoft 365 PowerShell. Then you're ready to use your custom sensitive information type in your policies and test that it's detecting the sensitive information as you intended.

> **NOTE**
> If you don't need the fine grained control that PowerShell provides, you can create custom sensitive information types in the Compliance center. For more information, see Create a custom sensitive information type.

Important disclaimer

Due to the variances in customer environments and content match requirements, Microsoft Support cannot assist in providing custom content-matching definitions; e.g., defining custom classifications or regular expression (also known as RegEx) patterns. For custom content-matching development, testing, and debugging, Microsoft 365 customers will need to rely upon internal IT resources, or use an external consulting resource such as Microsoft Consulting Services (MCS). Support engineers can provide limited support for the feature, but cannot provide assurances that any custom content-matching development will fulfill the customer's requirements or obligations. As an example of the type of support that can be provided, sample regular expression patterns may be provided for testing purposes. Or, support can assist with troubleshooting an existing RegEx pattern which is not triggering as expected with a single specific content example.

See Potential validation issues to be aware of in this topic.

For more information about the Boost.RegEx (formerly known as RegEx++) engine that's used for processing the text, see Boost.Regex 5.1.3.

Sample XML of a rule package

Here's the sample XML of the rule package that we'll create in this topic. Elements and attributes are explained in the sections below.

```
<?xml version="1.0" encoding="UTF-16"?>
<RulePackage xmlns="http://schemas.microsoft.com/office/2011/mce">
<RulePack id="DAD86A92-AB18-43BB-AB35-96F7C594ADAA">

What are your key requirements? [Rule, Entity, Pattern elements]

Before you get started, it's helpful to understand the basic structure of the XML schema for a rule, and how you can use this structure to define your custom sensitive information type so that it will identify the right content.

A rule defines one or more entities (sensitive information types), and each entity defines one or more patterns. A pattern is what a policy looks for when it evaluates content such as email and documents.

In this topic, the XML markup uses rule to mean the patterns that define an entity, also known as a sensitive information type. So in this topic, when you see rule, think entity or sensitive information type, not conditions and actions.

Simplest scenario: entity with one pattern

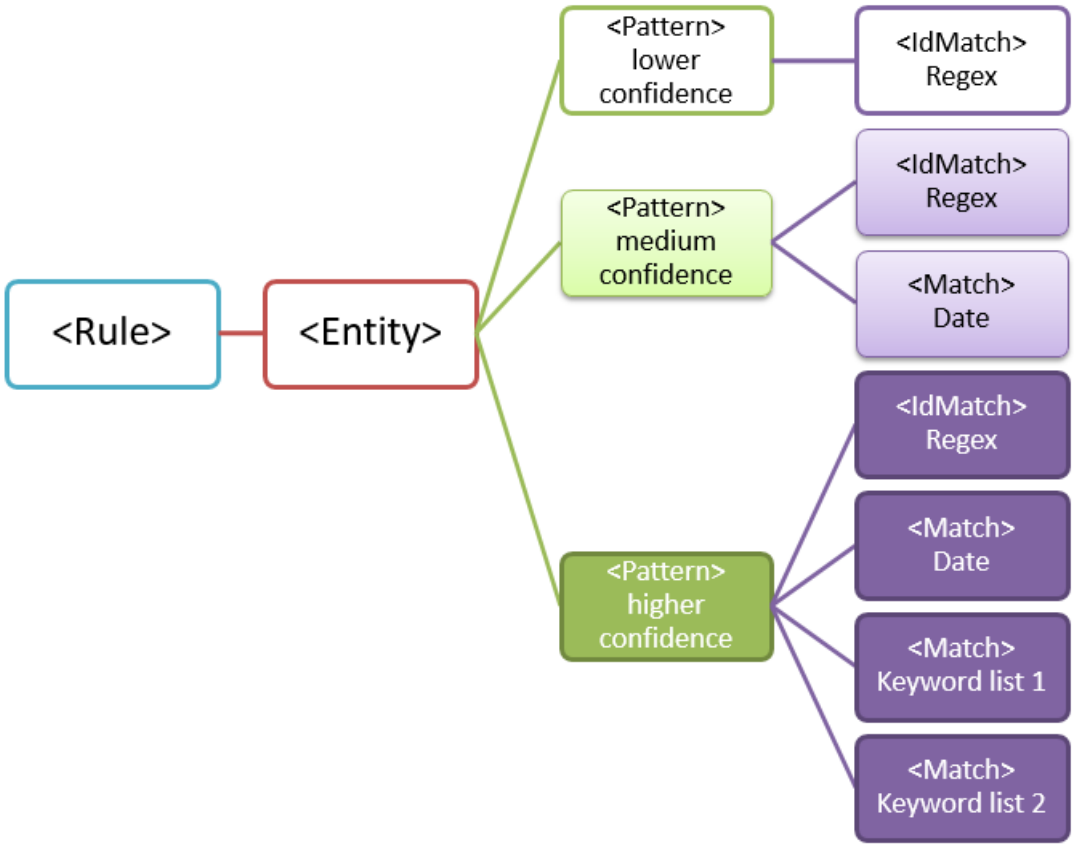
Here's the simplest scenario. You want your policy to identify content that contains your organization's employee ID, which is formatted as a nine-digit number. So the pattern refers to a regular expression contained in the rule that identifies nine-digit numbers. Any content containing a nine-digit number satisfies the pattern.

However, while simple, this pattern may identify many false positives by matching content that contains any nine-digit number that is not necessarily an employee ID.

More common scenario: entity with multiple patterns

For this reason, it's more common to define an entity by using more than one pattern, where the patterns identify supporting evidence (such as a keyword or date) in addition to the entity (such as a nine-digit number).

For example, to increase the likelihood of identifying content that contains an employee ID, you can define another pattern that also identifies a hire date, and define yet another pattern that identifies both a hire date and a keyword (such as "employee ID"), in addition to the nine-digit number.



Note a couple of important aspects of this structure:

- Patterns that require more evidence have a higher confidence level. This is useful because when you later use this sensitive information type in a policy, you can use more restrictive actions (such as block content) with only the higher-confidence matches, and you can use less restrictive actions (such as send notification) with the lower-confidence matches.
- The supporting IdMatch and Match elements reference regexes and keywords that are actually children of the Rule element, not the Pattern. These supporting elements are referenced by the Pattern but included in the Rule. This means that a single definition of a supporting element, like a regular expression or a keyword list, can be referenced by multiple entities and patterns.

What entity do you need to identify? [Entity element, id attribute]

An entity is a sensitive information type, such as a credit card number, that has a well-defined pattern. Each entity has a unique GUID as its ID.

Name the entity and generate its GUID

1. In your XML editor of choice, add the Rules and Entity elements.
2. Add a comment that contains the name of your custom entity — in this example, Employee ID. Later, you'll add the entity name to the localized strings section, and that name is what appears in the UI when you create a policy.
3. Generate a GUID for your entity. There are several ways to generate GUIDs, but you can do it easily in PowerShell by typing **[guid]::NewGuid()**. Later, you'll also add the entity GUID to the localized strings section.

```
<Rules>
  <!-- Employee ID -->
  <Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378">
  </Entity>
</Rules>
```

Add comment and name entity.

Generate GUID and add as id attribute.

What pattern do you want to match? [Pattern element, IdMatch element, Regex element]

The pattern contains the list of what the sensitive information type is looking for. This can include regexes, keywords, and built-in functions (which perform tasks like running regexes to find dates or addresses). Sensitive information types can have multiple patterns with unique confidences.

What all of the below patterns have in common is that they all reference the same regular expression, which looks for a nine-digit number (\d{9}) surrounded by white space (\s) ... (\s). This regular expression is referenced by the IdMatch element and is the common requirement for all patterns that look for the Employee ID entity. IdMatch is the identifier that the pattern is to trying to match, such as Employee ID or credit card number or social security number. A Pattern element must have exactly one IdMatch element.

```
<Rules>

  <!-- Employee ID -->
  <Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378">

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

  </Entity>

  <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>

</Rules>
```

Each Pattern has exactly one required IdMatch element, which references the same regex.

Regex defines the identifier the pattern is trying to match.

When satisfied, a pattern returns a count and confidence level, which you can use in the conditions in your policy. When you add a condition for detecting a sensitive information type to a policy, you can edit the count and confidence level as shown here. Confidence level (also called match accuracy) is explained later in this topic.

When content contains sensitive information *

Sensitive information type	Instance count min	Instance count max	Match accuracy min	Match accuracy max
U.S. Individual Taxpayer Identification Number (ITIN)	1	9	75	100
U.S. Social Security Number (SSN)	1	9	75	100
U.S. / U.K. Passport Number	1	9	75	100

When you create your regular expression, keep in mind that there are potential issues to be aware of. For example, if you write and upload a regex that identifies too much content, this can impact performance. To learn more about these potential issues, see the later section Potential validation issues to be aware of.

Do you want to require additional evidence? [Match element,

minCount attribute]

In addition to the IdMatch, a pattern can use the Match element to require additional supporting evidence, such as a keyword, regex, date, or address.

A Pattern can include multiple Match elements; they can be included directly in the Pattern element or combined by using the Any element. Match elements are joined by an implicit AND operator; all Match elements must be satisfied for the pattern to be matched. You can use the Any element to introduce AND or OR operators (more on that in a later section).

You can use the optional minCount attribute to specify how many instances of a match need to be found for each of the Match elements. For example, you can specify that a pattern is satisfied only when at least two keywords from a keyword list are found.

```
<Rules>

  <!-- Employee ID -->
  <Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378">

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
      <Match idRef="Keyword_employee" />
      <Match idRef="Keyword_badge" minCount="2" />
    </Pattern>

  </Entity>

  <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>
```

Keywords [Keyword, Group, and Term elements, matchStyle and caseSensitive attributes]

When you identify sensitive information, like an employee ID, you often want to require keywords as corroborative evidence. For example, in addition to matching a nine-digit number, you may want to look for words like "card", "badge", or "ID". To do this, you use the Keyword element. The Keyword element has an ID attribute that can be referenced by multiple Match elements in multiple patterns or entities.

Keywords are included as a list of Term elements in a Group element. The Group element has a matchStyle attribute with two possible values:

- **matchStyle="word"** Word match identifies whole words surrounded by white space or other delimiters. You should always use word unless you need to match parts of words or match words in Asian languages.
- **matchStyle="string"** String match identifies strings no matter what they're surrounded by. For example, "id" will match "bid" and "idea". Use string only when you need to match Asian words or if your keyword may be included as part of other strings.

Finally, you can use the caseSensitive attribute of the Term element to specify that the content must match the keyword exactly, including lower- and upper-case letters.

```
<Rules>

    <!-- Employee ID -->
    <Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378" >

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
        </Pattern>

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
        </Pattern>

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
            <Match idRef="Keyword_badge"/>
            <Match idRef="Keyword_employee"/>
        </Pattern>

    </Entity>
    <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>

    <Keyword id="Keyword_employee">
        <Group matchStyle="word">
            <Term>Identification</Term>
            <Term>Contoso Employee</Term>
        </Group>
    </Keyword>

    <Keyword id="Keyword_badge">
        <Group matchStyle="string">
            <Term>card</Term>
            <Term>badge</Term>
            <Term caseSensitive="true">ID</Term>
        </Group>
    </Keyword>

</Rules>
```

Match element uses idRef to reference Keyword element defined outside entity.

matchStyle can be either word or string.

A Term can be made case sensitive.

Regular expressions [Regex element]

In this example, the employee ID entity already uses the IdMatch element to reference a regex for the pattern — a nine-digit number surrounded by whitespace. In addition, a pattern can use a Match element to reference an additional Regex element to identify corroborative evidence, such as a five- or nine-digit number in the format of a US zip code.

Additional patterns such as dates or addresses [built-in functions]

In addition to the built-in sensitive information types, sensitive information types can also use built-in functions that can identify corroborative evidence such as a US date, EU date, expiration date, or US address. Microsoft 365 does not support uploading your own custom functions, but when you create a custom sensitive information type, your entity can reference the built-in functions.

For example, an employee ID badge has a hire date on it, so this custom entity can use the built-in function `Func_us_date` to identify a date in the format commonly used in the US.

For more information, see What the DLP functions look for.

```
<Rules>

  <!-- Employee ID -->
  <Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378">

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
      <Match idRef="Func_us_date" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
      <Match idRef="Keyword_employee" />
      <Match idRef="Keyword_badge" />
    </Pattern>

  </Entity>

  <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>

  <Keyword id="Keyword_employee">
    <Group matchStyle="word">
      <Term>Identification</Term>
      <Term>Contoso Employee</Term>
    </Group>
  </Keyword>

  <Keyword id="Keyword_badge">
    <Group matchStyle="string">
      <Term>card</Term>
      <Term>badge</Term>
      <Term>ID</Term>
    </Group>
  </Keyword>

</Rules>
```

Patterns can reference the built-in DLP functions to find corroborative evidence.

Because the functions are built in, they don't require a separate element in the Rules element.

Different combinations of evidence [Any element, minMatches and maxMatches attributes]

In a Pattern element, all IdMatch and Match elements are joined by an implicit AND operator — all of the matches must be satisfied before the pattern can be satisfied. However, you can create more flexible matching logic by using the Any element to group Match elements. For example, you can use the Any element to match all, none, or an exact subset of its children Match elements.

The Any element has optional minMatches and maxMatches attributes that you can use to define how many of the children Match elements must be satisfied before the pattern is matched. Note that these attributes define the number of Match elements that must be satisfied, not the number of instances of evidence found for the matches. To define a minimum number of instances for a specific match, such as two keywords from a list, use the minCount attribute for a Match element (see above).

Match at least one child Match element

If you want to require that only a minimum number of Match elements must be met, you can use the minMatches attribute. In effect, these Match elements are joined by an implicit OR operator. This Any element is satisfied if a US-formatted date or a keyword from either list is found.

```
<Any minMatches="1" >
     <Match idRef="Func_us_date" />
     <Match idRef="Keyword_employee" />
     <Match idRef="Keyword_badge" />
</Any>
```

Match an exact subset of any children Match elements

If you want to require that an exact number of Match elements must be met, you can set minMatches and maxMatches to the same value. This Any element is satisfied only if exactly one date or keyword is found — any more than that, and the pattern won't be matched.

```
<Any minMatches="1" maxMatches="1" >
     <Match idRef="Func_us_date" />
     <Match idRef="Keyword_employee" />
     <Match idRef="Keyword_badge" />
</Any>
```

Match none of children Match elements

If you want to require the absence of specific evidence for a pattern to be satisfied, you can set both minMatches and maxMatches to 0. This can be useful if you have a keyword list or other evidence that are likely to indicate a false positive.

For example, the employee ID entity looks for the keyword "card" because it might refer to an "ID card". However, if card appears only in the phrase "credit card", "card" in this content is unlikely to mean "ID card". So you can add "credit card" as a keyword to a list of terms that you want to exclude from satisfying the pattern.

```
<Any minMatches="0" maxMatches="0" >
    <Match idRef="Keyword_false_positives_local" />
    <Match idRef="Keyword_false_positives_intl" />
</Any>
```

Match a number of unique terms

If you want to match a number of unique terms, use the *uniqueResults* parameter, set to *true*, as shown in the following example:

```
<Pattern confidenceLevel="75">
    <IdMatch idRef="Salary_Revision_terms" />
    <Match idRef=" Salary_Revision_ID " minCount="3" uniqueResults="true" />
</Pattern>
```

In this example, a pattern is defined for salary revision using at least three unique matches.

How close to the entity must the other evidence be? [patternsProximity attribute]

Your sensitive information type is looking for a pattern that represents an employee ID, and as part of that pattern it's also looking for corroborative evidence like a keyword such as "ID". It makes sense that the closer together this evidence is, the more likely the pattern is to be an actual employee ID. You can determine how close other evidence in the pattern must be to the entity by using the required patternsProximity attribute of the Entity element.

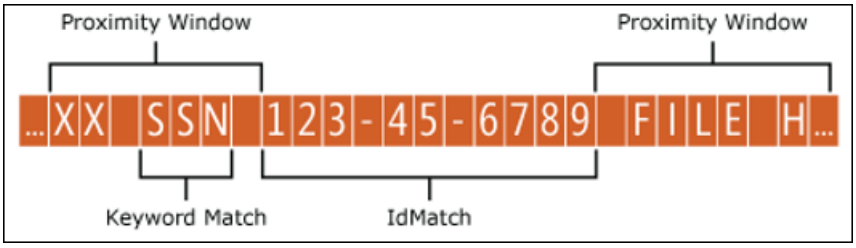
```
<!-- Employee ID -->
<Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378" patternsProximity="300" >

  <Pattern confidenceLevel="75">
    <IdMatch idRef="Regex_employee_id" />
    <Match idRef="Keyword_employee" />
  </Pattern>

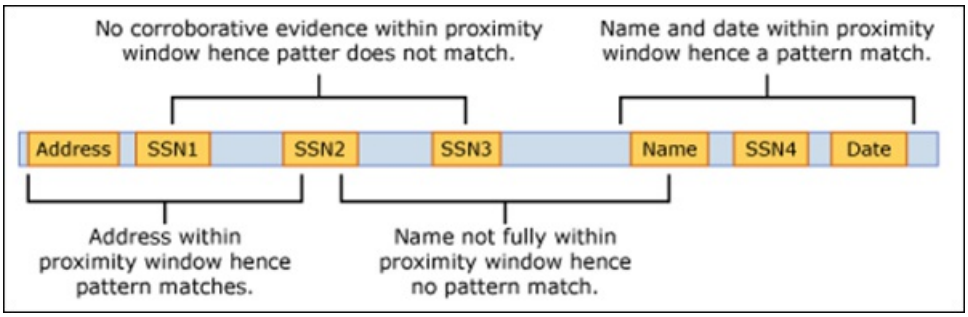
</Entity>
```

Attribute value defines the distance in Unicode characters from IdMatch to all other Match elements in the Pattern.

For each pattern in the entity, the patternsProximity attribute value defines the distance (in Unicode characters) from the IdMatch location for all other Matches specified for that Pattern. The proximity window is anchored by the IdMatch location, with the window extending to the left and right of the IdMatch.



The example below illustrates how the proximity window affects the pattern matching where IdMatch element for the employee ID custom entity requires at least one corroborating match of keyword or date. Only ID1 matches because for ID2 and ID3, either no or only partial corroborating evidence is found within the proximity window.



Note that for email, the message body and each attachment are treated as separate items. This means that the proximity window does not extend beyond the end of each of these items. For each item (attachment or body), both the idMatch and corroborative evidence needs to reside in that item.

What are the right confidence levels for different patterns? [confidenceLevel attribute, recommendedConfidence attribute]

The more evidence that a pattern requires, the more confidence you have that an actual entity (such as employee ID) has been identified when the pattern is matched. For example, you have more confidence in a pattern that requires a nine-digit ID number, hire date, and keyword in close proximity, than you do in a pattern that requires only a nine-digit ID number.

The Pattern element has a required confidenceLevel attribute. You can think of the value of confidenceLevel (an integer between 1 and 100) as a unique ID for each pattern in an entity — the patterns in an entity must have different confidence levels that you assign. The precise value of the integer doesn't matter — simply pick numbers that make sense to your compliance team. After you upload your custom sensitive information type and then create a policy, you can reference these confidence levels in the conditions of the rules that you create.

```
<!-- Employee ID -->
<Entity id="E1CC861E-3FE9-4A58-82DF-4BD259EAB378" patternsProximity="300">

  <Pattern confidenceLevel="60">
    <IdMatch idRef="Regex_employee_id" />
  </Pattern>

  <Pattern confidenceLevel="70">
    <IdMatch idRef="Regex_employee_id" />
    <Match idRef="Func_us_date" />
  </Pattern>

  <Pattern confidenceLevel="80">
    <IdMatch idRef="Regex_employee_id" />
    <Match idRef="Func_us_date" />
    <Any minMatches="1" >
        <Match idRef="Keyword_badge" />
        <Match idRef="Keyword_employee" />
    </Any>
    <Any maxMatches="0" >
        <Match idRef="Keyword_false_positives_local" />
        <Match idRef="Keyword_false_positives_intl" />
    </Any>
  </Pattern>

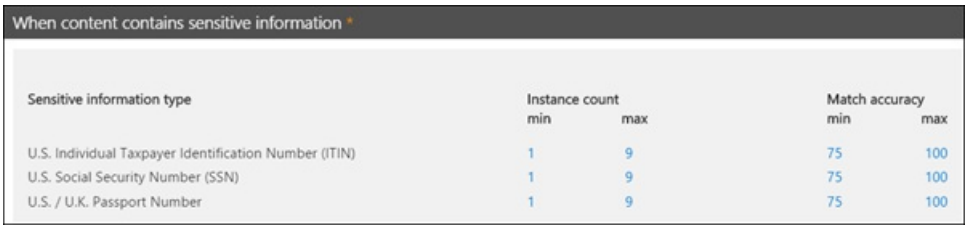
</Entity>
```

The more evidence the Pattern requires, the higher the confidence level.

In addition to confidenceLevel for each Pattern, the Entity has a recommendedConfidence attribute. The recommended confidence attribute can be thought of as the default confidence level for the rule. When you create a rule in a policy, if you don't specify a confidence level for the rule to use, that rule will match based on the recommended confidence level for the entity. Please note that the recommendedConfidence attribute is mandatory for each Entity ID in the Rule Package, if missing you won't be able to save policies that use the Sensitive Information Type.

Do you want to support other languages in the UI of the Compliance center? [LocalizedStrings element]

If your compliance team uses the Microsoft 365 Compliance center to create polices policies in different locales and in different languages, you can provide localized versions of the name and description of your custom sensitive information type. When your compliance team uses Microsoft 365 in a language that you support, they'll see the localized name in the UI.



The Rules element must contain a LocalizedStrings element, which contains a Resource element that references the GUID of your custom entity. In turn, each Resource element contains one or more Name and Description elements that each use the langcode attribute to provide a localized string for a specific language.

```
  <LocalizedStrings>
    <Resource idRef="E1CC861E-3FE9-4A58-82DF-4BD259EAB378">
      <Name default="true" langcode="en-us">Employee ID</Name>
      <Description default="true" langcode="en-us">
        A custom classification for detecting Employee IDs.
      </Description>
      <Name default="true" langcode="de-de">Name for German locale</Name>
      <Description default="true" langcode="de-de">
        Description for German locale.
      </Description>
    </Resource>

  </LocalizedStrings>
 </Rules>
</RulePackage>
```

Resource element references GUID of the entity.

Name and Description elements use langcode attribute to specify strings for a locale.

Note that you use localized strings only for how your custom sensitive information type appears in the UI of the Compliance center. You can't use localized strings to provide different localized versions of a keyword list or regular expression.

Other rule package markup [RulePack GUID]

Finally, the beginning of each RulePackage contains some general information that you need to fill in. You can use the following markup as a template and replace the ". . ." placeholders with your own info.

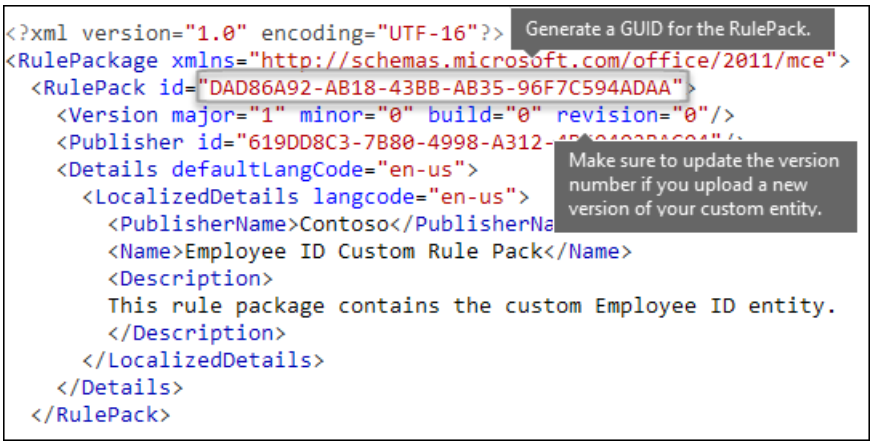
Most importantly, you'll need to generate a GUID for the RulePack. Above, you generated a GUID for the entity; this is a second GUID for the RulePack. There are several ways to generate GUIDs, but you can do it easily in PowerShell by typing [guid]::NewGuid().

The Version element is also important. When you upload your rule package for the first time, Microsoft 365 notes the version number. Later, if you update the rule package and upload a new version, make sure to update the version number or Microsoft 365 won't deploy the rule package.

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="http://schemas.microsoft.com/office/2011/mce">
  <RulePack id=". . .">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id=". . ." />
    <Details defaultLangCode=". . .">
      <LocalizedDetails langcode=" . . . ">
         <PublisherName>. . .</PublisherName>
         <Name>. . .</Name>
         <Description>. . .</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

  <Rules>
  . . .
  </Rules>
</RulePackage>
```

When complete, your RulePack element should look like this.



```
<?xml version="1.0" encoding="UTF-16"?>
<RulePackage xmlns="http://schemas.microsoft.com/office/2011/mce">
  <RulePack id="DAD86A92-AB18-43BB-AB35-96F7C594ADAA">
    <Version major="1" minor="0" build="0" revision="0"/>
    <Publisher id="619DD8C3-7B80-4998-A312-
    <Details defaultLangCode="en-us">
      <LocalizedDetails langcode="en-us">
        <PublisherName>Contoso</PublisherNa
        <Name>Employee ID Custom Rule Pack</Name>
        <Description>
        This rule package contains the custom Employee ID entity.
        </Description>
      </LocalizedDetails>
    </Details>
  </RulePack>
```

Changes for Exchange Online

Previously, you might have used Exchange Online PowerShell to import your custom sensitive information types for DLP. Now your custom sensitive information types can be used in both the Exchange admin center and the Compliance center. As part of this improvement, you should use Compliance center PowerShell to import your custom sensitive information types — you can't import them from the Exchange PowerShell anymore. Your custom sensitive information types will continue to work just like before; however, it may take up to one hour for changes made to custom sensitive information types in the Compliance center to appear in the Exchange admin center.

Note that in the Compliance center, you use the **New-DlpSensitiveInformationTypeRulePackage** cmdlet to upload a rule package. (Previously, in the Exchange admin center, you used the **ClassificationRuleCollection**` cmdlet.)

Upload your rule package

To upload your rule package, do the following steps:

1. Save it as an .xml file with Unicode encoding.
2. Connect to Compliance center PowerShell
3. Use the following syntax:

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData (Get-Content -Path "PathToUnicodeXMLFile" -
   Encoding Byte -ReadCount 0)
   ```

   This example uploads the Unicode XML file named MyNewRulePack.xml from C:\My Documents.

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData (Get-Content -Path "C:\My
   Documents\MyNewRulePack.xml" -Encoding Byte -ReadCount 0)
   ```

   For detailed syntax and parameter information, see New-DlpSensitiveInformationTypeRulePackage.

   > **NOTE**
   > The maximum number of rule packages supported is 10, but each package can contain the definition of multiple sensitive information types.

4. To verify that you've successfully created a new sensitive information type, do any of the following steps:

   - Run the Get-DlpSensitiveInformationTypeRulePackage cmdlet to verify the new rule package is

listed:

```
Get-DlpSensitiveInformationTypeRulePackage
```

- Run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information type is listed:

  ```
  Get-DlpSensitiveInformationType
  ```

  For custom sensitive information types, the Publisher property value will be something other than Microsoft Corporation.

- Replace <Name> with the Name value of the sensitive information type (example: Employee ID) and run the Get-DlpSensitiveInformationType cmdlet:

  ```
  Get-DlpSensitiveInformationType -Identity "<Name>"
  ```

Potential validation issues to be aware of

When you upload your rule package XML file, the system validates the XML and checks for known bad patterns and obvious performance issues. Here are some known issues that the validation checks for — a regular expression:

- Cannot begin or end with alternator "|", which matches everything because it's considered an empty match.

  For example, "|a" or "b|" will not pass validation.

- Cannot begin or end with a ".{0,m}" pattern, which has no functional purpose and only impairs performance.

  For example, ".{0,50}ASDF" or "ASDF.{0,50}" will not pass validation.

- Cannot have ".{0,m}" or ".{1,m}" in groups, and cannot have ".*" or ".+" in groups.

  For example, "(.{0,50000})" will not pass validation.

- Cannot have any character with "{0,m}" or "{1,m}" repeaters in groups.

  For example, "(a*)" will not pass validation.

- Cannot begin or end with ".{1,m}"; instead, use just "."

  For example, ".{1,m}asdf" will not pass validation; instead, use just ".asdf".

- Cannot have an unbounded repeater (such as "*" or "+") on a group.

  For example, "(xx)*" and "(xx)+" will not pass validation.

- Keywords have a maximum of 50 characters in Length. If you have a keyword within a Group exceeding this, a suggested solution is to create the Group of terms as a Keyword Dictionary and reference the GUID of the Keyword Dictionary within the XML structure as part of the Entity for Match or idMatch in the file.

- Each Custom Sensitive Information Type can have a maximum of 2048 keywords total.

- The maximum size of Keyword Dictionaries in a single tenant is 100 kilobytes compressed. Reference the same dictionary as many times as necessary when creating custom sensitive information types. Start with creating custom keyword lists in the sensitive information type and use keyword dictionaries if you have more than 2048 keywords in a keyword list or a keyword is larger than 50 characters in length.

- Ensure each Entity element contains a recommendedConfidence attribute.
- When using the PowerShell Cmdlet there is a maximum return size of the Deserialized Data of approximately 1 megabyte. This will affect the size of your rule pack XML file. Keep the uploaded file limited to a 770 kilobyte maximum as a suggested limit for consistent results without error when processing.
- The XML structure does not require formatting characters such as spaces, tabs, or carriage return/linefeed entries. Take note of this when optimizing for space on uploads. Tools such as Microsoft Visual Code provide join line features to compact the XML file.

If a custom sensitive information type contains an issue that may affect performance, it won't be uploaded and you may see one of these error messages:

- **Generic quantifiers which match more content than expected (e.g., '+', '*')**
- **Lookaround assertions**
- **Complex grouping in conjunction with general quantifiers**

Recrawl your content to identify the sensitive information

Microsoft 365 uses the search crawler to identify and classify sensitive information in site content. Content in SharePoint Online and OneDrive for Business sites is recrawled automatically whenever it's updated. But to identify your new custom type of sensitive information in all existing content, that content must be recrawled.

In Microsoft 365, you can't manually request a recrawl of an entire tenant, but you can do this for a site collection, list, or library — see Manually request crawling and re-indexing of a site, a library or a list.

Remove a custom sensitive information type

> **NOTE**
> Before your remove a custom sensitive information type, verify that no DLP policies or Exchange mail flow rules (also known as transport rules) still reference the sensitive information type.

In Compliance center PowerShell, there are two methods to remove custom sensitive information types:

- **Remove individual custom sensitive information types**: Use the method documented in Modify a custom sensitive information type. You export the custom rule package that contains the custom sensitive information type, remove the sensitive information type from the XML file, and import the updated XML file back into the existing custom rule package.
- **Remove a custom rule package and all custom sensitive information types that it contains**: This method is documented in this section.

1. Connect to Compliance center PowerShell
2. To remove a custom rule package, use the Remove-DlpSensitiveInformationTypeRulePackage cmdlet:

   ```
   Remove-DlpSensitiveInformationTypeRulePackage -Identity "RulePackageIdentity"
   ```

   You can use the Name value (for any language) or the `RulePack id` (GUID) value to identify the rule package.

   This example removes the rule package named "Employee ID Custom Rule Pack".

```
Remove-DlpSensitiveInformationTypeRulePackage -Identity "Employee ID Custom Rule Pack"
```

For detailed syntax and parameter information, see Remove-DlpSensitiveInformationTypeRulePackage.

3. To verify that you've successfully removed a custom sensitive information type, do any of the following steps:

   - Run the Get-DlpSensitiveInformationTypeRulePackage cmdlet and verify the rule package is no longer listed:

     ```
     Get-DlpSensitiveInformationTypeRulePackage
     ```

   - Run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information types in the removed rule package are no longer listed:

     ```
     Get-DlpSensitiveInformationType
     ```

     For custom sensitive information types, the Publisher property value will be something other than Microsoft Corporation.

   - Replace <Name> with the Name value of the sensitive information type (for example, Employee ID) and run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information type is no longer listed:

     ```
     Get-DlpSensitiveInformationType -Identity "<Name>"
     ```

Modify a custom sensitive information type

In Compliance center PowerShell, modifying a custom sensitive information type requires you to:

1. Export the existing rule package that contains the custom sensitive information type to an XML file (or use the existing XML file if you have it).
2. Modify the custom sensitive information type in the exported XML file.
3. Import the updated XML file back into the existing rule package.

To connect to Compliance Center PowerShell, see Connect to Compliance Center PowerShell.

Step 1: Export the existing rule package to an XML file

> **NOTE**
> If you have a copy of the XML file (for example, you just created and imported it), you can skip to the next step to modify the XML file.

1. If you don't already know it, run the Get-DlpSensitiveInformationTypeRulePackage cmdlet to find the name of the custom rule package:

```
Get-DlpSensitiveInformationTypeRulePackage
```

> **NOTE**
> The built-in rule package that contains the built-in sensitive information types is named Microsoft Rule Package. The rule package that contains the custom sensitive information types that you created in the Compliance center UI is named Microsoft.SCCManaged.CustomRulePack.

2. Use the Get-DlpSensitiveInformationTypeRulePackage cmdlet to store the custom rule package to a variable:

   ```
   $rulepak = Get-DlpSensitiveInformationTypeRulePackage -Identity "RulePackageName"
   ```

   For example, if the name of the rule package is "Employee ID Custom Rule Pack", run the following cmdlet:

   ```
   $rulepak = Get-DlpSensitiveInformationTypeRulePackage -Identity "Employee ID Custom Rule Pack"
   ```

3. Use the Set-Content cmdlet to export the custom rule package to an XML file:

   ```
   Set-Content -Path "XMLFileAndPath" -Encoding Byte -Value
   $rulepak.SerializedClassificationRuleCollection
   ```

   This example export the rule package to the file named ExportedRulePackage.xml in the C:\My Documents folder.

   ```
   Set-Content -Path "C:\My Documents\ExportedRulePackage.xml" -Encoding Byte -Value
   $rulepak.SerializedClassificationRuleCollection
   ```

Step 2: Modify the sensitive information type in the exported XML file

Sensitive information types in the XML file and other elements in the file are described earlier in this topic.

Step 3: Import the updated XML file back into the existing rule package

To import the updated XML back into the existing rule package, use the Set-DlpSensitiveInformationTypeRulePackage cmdlet:

```
Set-DlpSensitiveInformationTypeRulePackage -FileData ([Byte[]]$(Get-Content -Path "C:\My Documents\External
Sensitive Info Type Rule Collection.xml" -Encoding Byte -ReadCount 0))
```

For detailed syntax and parameter information, see Set-DlpSensitiveInformationTypeRulePackage.

Reference: Rule package XML schema definition

You can copy this markup, save it as an XSD file, and use it to validate your rule package XML file.

```
<?xml version="1.0" encoding="utf-8"?>
<xs:schema xmlns:mce="http://schemas.microsoft.com/office/2011/mce"
           targetNamespace="http://schemas.microsoft.com/office/2011/mce"
           xmlns:xs="https://www.w3.org/2001/XMLSchema"
           elementFormDefault="qualified"
           attributeFormDefault="unqualified"
           id="RulePackageSchema">
  <!-- Use include if this schema has the same target namespace as the schema being referenced, otherwise
use import -->
  <xs:element name="RulePackage" type="mce:RulePackageType"/>
  <xs:simpleType name="LangType">
```

```
<xs:simpleType name="LangType">
  <xs:union memberTypes="xs:language">
    <xs:simpleType>
      <xs:restriction base="xs:string">
        <xs:enumeration value=""/>
      </xs:restriction>
    </xs:simpleType>
  </xs:union>
</xs:simpleType>
<xs:simpleType name="GuidType" final="#all">
  <xs:restriction base="xs:token">
    <xs:pattern value="[0-9a-fA-F]{8}\-([0-9a-fA-F]{4}\-){3}[0-9a-fA-F]{12}"/>

Create a keyword dictionary

2/18/2021 • 6 minutes to read • Edit Online

Data loss prevention (DLP) can identify, monitor, and protect your sensitive items. Identifying sensitive items sometimes requires looking for keywords, particularly when identifying generic content (such as healthcare-related communication), or inappropriate or explicit language. Although you can create keyword lists in sensitive information types, keyword lists are limited in size and require modifying XML to create or edit them. Keyword dictionaries provide simpler management of keywords and at a much larger scale, supporting up to 1MB of terms (post compression) in the dictionary and support any language. The tenant limit is also 1MB after compression. 1MB of post compression limit means that all dictionaries combined across a tenant can have close to 1 million character.

NOTE

Microsoft 365 Information Protection now supports in preview double byte character set languages for:

- Chinese (simplified)
- Chinese (traditional)
- Korean
- Japanese

This support is available for sensitive information types. See, Information protection support for double byte character sets release notes (preview) for more information.

Basic steps to creating a keyword dictionary

The keywords for your dictionary could come from a variety of sources, most commonly from a file (such as a .csv or .txt list) imported in the service or by PowerShell cmdlet, from a list you enter directly in the PowerShell cmdlet, or from an existing dictionary. When you create a keyword dictionary, you follow the same core steps:

1. Use the **Security & Compliance Center** (https://protection.office.com) or connect to **Security & Compliance Center PowerShell**.
2. **Define or load your keywords from your intended source**. The wizard and the cmdlet both accept a comma-separated list of keywords to create a custom keyword dictionary, so this step will vary slightly depending on where your keywords come from. Once loaded, they're encoded and converted to a byte array before they're imported.
3. **Create your dictionary**. Choose a name and description and create your dictionary.

Create a keyword dictionary using the Security & Compliance Center

Use the following steps to create and import keywords for a custom dictionary:

1. Connect to the Security & Compliance Center (https://protection.office.com).
2. Navigate to **Classifications > Sensitive info types**.
3. Select **Create** and enter a **Name** and **Description** for your sensitive info type, then select **Next**
4. Select **Add an element**, then select **Dictionary (Large keywords)** in the **Detect content containing** drop-down list.

5. Select **Add a dictionary**
6. Under the Search control, select **You can create new keyword dictionaries here**.
7. Enter a **Name** for your custom dictionary.
8. Select **Import**, and select either **From text** or **From csv** depending on your keyword file type.
9. In the file dialog, select the keyword file from your local PC or network file share, then select **Open**.
10. Select **Save**, then select your custom dictionary from the **Keyword dictionaries** list.
11. Select **Add**, then select **Next**.
12. Review and finalize your sensitive info type selections, then select **Finish**.

Create a keyword dictionary from a file using PowerShell

Often when you need to create a large dictionary, it's to use keywords from a file or a list exported from some other source. In this case, you'll create a keyword dictionary containing a list of inappropriate language to screen in external email. You must first connect to Security & Compliance Center PowerShell.

1. Copy the keywords into a text file and make sure that each keyword is on a separate line.
2. Save the text file with Unicode encoding. In Notepad > **Save As** > **Encoding** > **Unicode**.
3. Read the file into a variable by running this cmdlet:

   ```
   $fileData = Get-Content <filename> -Encoding Byte -ReadCount 0
   ```

4. Create the dictionary by running this cmdlet:

   ```
   New-DlpKeywordDictionary -Name <name> -Description <description> -FileData $fileData
   ```

Modifying an existing keyword dictionary

You might need to modify keywords in one of your keyword dictionaries, or modify one of the built-in dictionaries. Currently, your can only update a custom keyword dictionary using PowerShell.

For example, we'll modify some terms in PowerShell, save the terms locally where you can modify them in an editor, and then update the previous terms in place.

First, retrieve the dictionary object:

```
$dict = Get-DlpKeywordDictionary -Name "Diseases"
```

Printing `$dict` will show the various variables. The keywords themselves are stored in an object on the backend, but `$dict.KeywordDictionary` contains a string representation of them, which you'll use to modify the dictionary.

Before you modify the dictionary, you need to turn the string of terms back into an array using the `.split(',')` method. Then you'll clean up the unwanted spaces between the keywords with the `.trim()` method, leaving just the keywords to work with.

```
$terms = $dict.KeywordDictionary.split(',').trim()
```

Now you'll remove some terms from the dictionary. Because the example dictionary has only a few keywords, you could just as easily skip to exporting the dictionary and editing it in Notepad, but dictionaries generally contain a large amount of text, so you'll first learn this way to edit them easily in PowerShell.

In the last step, you saved the keywords to an array. There are several ways to remove items from an array, but as a straightforward approach, you'll create an array of the terms you want to remove from the dictionary, and then copy only the dictionary terms to it that aren't in the list of terms to remove.

Run the command `$terms` to show the current list of terms. The output of the command looks like this:

`aarskog's syndrome` `abandonment` `abasia` `abderhalden-kaufmann-lignac` `abdominalgia` `abduction contracture` `abetalipoproteinemia` `abiotrophy` `ablatio` `ablation` `ablepharia` `abocclusion` `abolition` `aborter` `abortion` `abortus` `aboulomania` `abrami's disease`

Run this command to specify the terms that you want to remove:

```
$termsToRemove = @('abandonment', 'ablatio')
```

Run this command to actually remove the terms from the list:

```
$updatedTerms = $terms | Where-Object{ $_ -notin $termsToRemove }
```

Run the command `$updatedTerms` to show the updated list of terms. The output of the command looks like this (the specified terms have been removed):

`aarskog's syndrome` `abasia` `abderhalden-kaufmann-lignac` `abdominalgia` `abduction contracture` `abetalipo proteinemia` `abiotrophy` `ablation` `ablepharia` `abocclusion` `abolition` `aborter` `abortion` `abortus` `aboulomania` `abrami's disease`

```
Now save the dictionary locally and add a few more terms. You could add the terms right here in PowerShell,
but you'll still need to export the file locally to ensure it's saved with Unicode encoding and contains the
BOM.

Save the dictionary locally by running the following:

```powershell
Set-Content $updatedTerms -Path "C:\myPath\terms.txt"
```

Now simply open the file, add your additional terms, and save with Unicode encoding (UTF-16). Now you'll upload the updated terms and update the dictionary in place.

```
PS> Set-DlpKeywordDictionary -Identity "Diseases" -FileData (Get-Content -Path "C:myPath\terms.txt" -
Encoding Byte -ReadCount 0)
```

Now the dictionary has been updated in place. Note that the `Identity` field takes the name of the dictionary. If you wanted to also change the name of your dictionary using the `set-` cmdlet, you would just need to add the `-Name` parameter to what's above with your new dictionary name.

Using keyword dictionaries in custom sensitive information types and DLP policies

Keyword dictionaries can be used as part of the match requirements for a custom sensitive information type, or as a sensitive information type themselves. Both require you to create a custom sensitive information type.
```

Follow the instructions in the linked article to create a sensitive information type. Once you have the XML, you'll need the GUID identifier for the dictionary to use it.

```
<Entity id="9e5382d0-1b6a-42fd-820e-44e0d3b15b6e" patternsProximity="300" recommendedConfidence="75">
    <Pattern confidenceLevel="75">
        <IdMatch idRef=". . ."/>
    </Pattern>
</Entity>
```

To get the identity of your dictionary, run this command and copy the **Identity** property value:

```
Get-DlpKeywordDictionary -Name "Diseases"
```

The output of the command looks like this:

```
RunspaceId : 138e55e7-ea1e-4f7a-b824-79f2c4252255 Identity : 8d2d44b0-91f4-41f2-94e0-21c1c5b5fc9f
Name : Diseases Description : Names of diseases and injuries from ICD-10-CM lexicon
KeywordDictionary : aarskog's syndrome, abandonment, abasia, abderhalden-kaufmann-lignac, abdominalgia,
abduction contracture, abetalipo
proteinemia, abiotrophy, ablatio, ablation, ablepharia, abocclusion, abolition, aborter, abortion, abortus,
aboulomania,
abrami's disease, abramo IsValid : True ObjectState : Unchanged
```

Paste the identity into your custom sensitive information type's XML and upload it. Now your dictionary will appear in your list of sensitive information types and you can use it right in your policy, specifying how many keywords are required to match.

```
<Entity id="d333c6c2-5f4c-4131-9433-db3ef72a89e8" patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="8d2d44b0-91f4-41f2-94e0-21c1c5b5fc9f" />
      </Pattern>
    </Entity>
    <LocalizedStrings>
      <Resource idRef="d333c6c2-5f4c-4131-9433-db3ef72a89e8">
        <Name default="true" langcode="en-us">Diseases</Name>
        <Description default="true" langcode="en-us">Detects various diseases</Description>
      </Resource>
    </LocalizedStrings>
```

Document Fingerprinting

11/2/2020 • 6 minutes to read • Edit Online

Information workers in your organization handle many kinds of sensitive information during a typical day. In the Security & Compliance Center, Document Fingerprinting makes it easier for you to protect this information by identifying standard forms that are used throughout your organization. This topic describes the concepts behind Document Fingerprinting and how to create one by using PowerShell.

Basic scenario for Document Fingerprinting

Document Fingerprinting is a Data Loss Prevention (DLP) feature that converts a standard form into a sensitive information type, which you can use in the rules of your DLP policies. For example, you can create a document fingerprint based on a blank patent template and then create a DLP policy that detects and blocks all outgoing patent templates with sensitive content filled in. Optionally, you can set up policy tips to notify senders that they might be sending sensitive information, and the sender should verify that the recipients are qualified to receive the patents. This process works with any text-based forms used in your organization. Additional examples of forms that you can upload include:

- Government forms
- Health Insurance Portability and Accountability Act (HIPAA) compliance forms
- Employee information forms for Human Resources departments
- Custom forms created specifically for your organization

Ideally, your organization already has an established business practice of using certain forms to transmit sensitive information. After you upload an empty form to be converted to a document fingerprint and set up a corresponding policy, the DLP detects any documents in outbound mail that match that fingerprint.

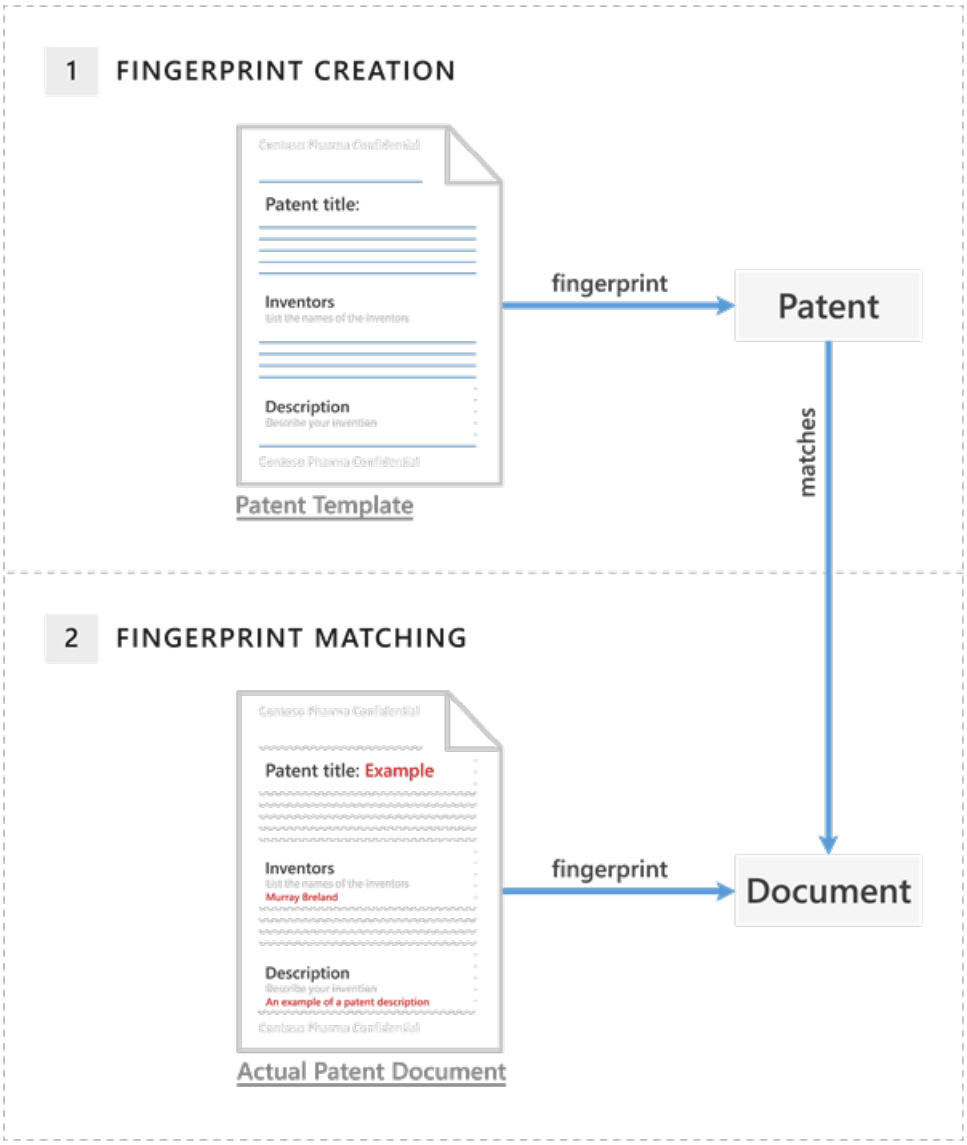
How Document Fingerprinting works

You've probably already guessed that documents don't have actual fingerprints, but the name helps explain the feature. In the same way that a person's fingerprints have unique patterns, documents have unique word patterns. When you upload a file, DLP identifies the unique word pattern in the document, creates a document fingerprint based on that pattern, and uses that document fingerprint to detect outbound documents containing the same pattern. That's why uploading a form or template creates the most effective type of document fingerprint. Everyone who fills out a form uses the same original set of words and then adds his or her own words to the document. As long as the outbound document isn't password protected and contains all the text from the original form, DLP can determine if the document matches the document fingerprint.

> **IMPORTANT**
> For now, DLP can use document fingerprinting as a detection method in Exchange online only.

The following example shows what happens if you create a document fingerprint based on a patent template, but you can use any form as a basis for creating a document fingerprint.

Example of a patent document matching a document fingerprint of a patent template



The patent template contains the blank fields "Patent title," "Inventors," and "Description" and descriptions for each of those fields—that's the word pattern. When you upload the original patent template, it's in one of the supported file types and in plain text. DLP converts this word pattern into a document fingerprint, which is a small Unicode XML file containing a unique hash value representing the original text, and the fingerprint is saved as a data classification in Active Directory. (As a security measure, the original document itself isn't stored on the service; only the hash value is stored, and the original document can't be reconstructed from the hash value.) The patent fingerprint then becomes a sensitive information type that you can associate with a DLP policy. After you associate the fingerprint with a DLP policy, DLP detects any outbound emails containing documents that match the patent fingerprint and deals with them according to your organization's policy.

For example, you might want to set up a DLP policy that prevents regular employees from sending outgoing messages containing patents. DLP will use the patent fingerprint to detect patents and block those emails. Alternatively, you might want to let your legal department to be able to send patents to other organizations because it has a business need for doing so. You can allow specific departments to send sensitive information by creating exceptions for those departments in your DLP policy, or you can allow them to override a policy tip with a business justification.

Supported file types

Document Fingerprinting supports the same file types that are supported in mail flow rules (also known as transport rules). For a list of supported file types, see Supported file types for mail flow rule content inspection. One quick note about file types: neither mail flow rules nor Document Fingerprinting supports the .dotx file type, which can be confusing because that's a template file in Word. When you see the word "template" in this and other Document Fingerprinting topics, it refers to a document that you have established as a standard form, not

the template file type.

Limitations of document fingerprinting

Document Fingerprinting won't detect sensitive information in the following cases:

- Password protected files
- Files that contain only images
- Documents that don't contain all the text from the original form used to create the document fingerprint

Use PowerShell to create a classification rule package based on document fingerprinting

Note that you can currently create a document fingerprint only by using PowerShell in the Security & Compliance Center. To connect, see Connect to Security & Compliance Center PowerShell.

DLP uses classification rule packages to detect sensitive content. To create a classification rule package based on a document fingerprint, use the **New-DlpFingerprint** and **New-DlpSensitiveInformationType** cmdlets. Because the results of **New-DlpFingerprint** aren't stored outside the data classification rule, you always run **New-DlpFingerprint** and **New-DlpSensitiveInformationType** or **Set-DlpSensitiveInformationType** in the same PowerShell session. The following example creates a new document fingerprint based on the file C:\My Documents\Contoso Employee Template.docx. You store the new fingerprint as a variable so you can use it with the **New-DlpSensitiveInformationType** cmdlet in the same PowerShell session.

```
$Employee_Template = Get-Content "C:\My Documents\Contoso Employee Template.docx" -Encoding byte -ReadCount
0
$Employee_Fingerprint = New-DlpFingerprint -FileData $Employee_Template -Description "Contoso Employee
Template"
```

Now, let's create a new data classification rule named "Contoso Employee Confidential" that uses the document fingerprint of the file C:\My Documents\Contoso Customer Information Form.docx.

```
$Customer_Form = Get-Content "C:\My Documents\Contoso Customer Information Form.docx" -Encoding byte -
ReadCount 0
$Customer_Fingerprint = New-DlpFingerprint -FileData $Customer_Form -Description "Contoso Customer
Information Form"
New-DlpSensitiveInformationType -Name "Contoso Customer Confidential" -Fingerprints $Customer_Fingerprint -
Description "Message contains Contoso customer information."
```

You can now use the **Get-DlpSensitiveInformationType** cmdlet to find all DLP data classification rule packages, and in this example, "Contoso Customer Confidential" is part of the data classification rule packages list.

Finally, add the "Contoso Customer Confidential" data classification rule package to a DLP policy in the Security & Compliance Center. This example adds a rule to an existing DLP policy named "ConfidentialPolicy".

```
New-DlpComplianceRule -Name "ContosoConfidentialRule" -Policy "ConfidentialPolicy" -
ContentContainsSensitiveInformation @{Name="Contoso Customer Confidential"} -BlockAccess $True
```

You can also use the data classification rule package in mail flow rules in Exchange Online, as shown in the following example. To run this command, you first need to Connect to Exchange Online PowerShell. Also note that it takes time for the rule package to sync from the Security & Compliance Center to the Exchange admin center.

```
New-TransportRule -Name "Notify :External Recipient Contoso confidential" -NotifySender NotifyOnly -Mode
Enforce -SentToScope NotInOrganization -MessageContainsDataClassification @{Name=" Contoso Customer
Confidential"}
```

DLP now detects documents that match the Contoso Customer Form.docx document fingerprint.

For syntax and parameter information, see:

- New-DlpFingerprint
- New-DlpSensitiveInformationType
- Remove-DlpSensitiveInformationType
- Set-DlpSensitiveInformationType
- Get-DlpSensitiveInformationType

What the DLP functions look for

11/2/2020 • 10 minutes to read • Edit Online

Data loss prevention (DLP) policies can use sensitive information types to identify sensitive items. Credit card number and EU debit card number are examples of sensitive information types. Sensitive information types look for specific patterns. Sensitive information types validate the data by looking at it's format, it's checksums, and looks for relevant keywords or other information. Some of this functionality is performed by internal functions. For example, the Credit Card Number sensitive information type uses a function to look for dates that are formatted like an expiration date. This helps to corroborate that a number is a credit card number.

This article explains what these functions look for, to help you understand how the predefined sensitive information types work. For more information, see Sensitive information type entity definitions

Table of functions

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_Argentina_Unique_Tax_Key	detects and validates Argentina Unique tax key	no	
Func_aba_routing	detects ABA routing number	yes	
Func_alabama_drivers_license_number	detects Alabama driver's license number	no	
Func_alaska_delaware_oregon_drivers_license_number	detects Alaska, Delaware, Oregon driver's license number	no	
Func_alaska_drivers_license_number	detects Alaska driver's license number	no	
Func_alberta_drivers_license_number	detects Alberta driver's license number	no	
Func_Argentina_Unique_Tax_Key	detects Argentina Unique tax key	no	
Func_arizona_drivers_license_number	detects Arizona driver's license number	no	
Func_arkansas_drivers_license_number	detects Arkansas driver's license number	no	
Func_australian_business_number	detects Australia business number	no	
Func_Australian_Company_Number	detects Australia company number	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_australian_medical_account_number	detects Australia medical account number	no	
Func_australian_tax_file_number	detects Australia tax file number	yes	
Func_austria_eu_ssn_or_equivalent	detects Austria social security number	no	
Func_austria_eu_tax_file_number	detects Austria tax file number	no	
Func_Austria_Value_Added_Tax	detects Austria Value Added Tax	no	
Func_belgium_national_number	detects Belgium national number	no	
Func_belgium_value_added_tax_number	detects Belgium value added tax number	no	
Func_brazil_cnpj	detects Brazil legal entity number (CNPJ)	yes	
Func_brazil_cpf	detects Brazil CPF	yes	
Func_brazil_rg	detects Brazil RG	no	
Func_british_columbia_drivers_license_number	detects British Columbia driver's license number	no	
Func_bulgaria_eu_national_id_card	detects Bulgaria uniform civil number	no	
Func_california_drivers_license_number	detects California driver's license number	no	
Func_canadian_sin	detects Canada sin	yes	
Func_chile_id_card	detects Chile ID card	no	
Func_china_resident_id	detects China-resident ID	no	
Func_colorado_drivers_license_number	detects Colorado driver's license number	no	
Func_connecticut_drivers_license_number	detects Connecticut driver's license number	no	
Func_credit_card	detects credit card	yes	no
Func_croatia_id_card	detects Croatia ID card	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_croatia_oib_number	detects Croatia OIB number	no	
Func_cyprus_eu_tax_file_number	detects Cyprus tax file number	no	
Func_czech_id_card	detects Czech ID card	no	
Func_czech_id_card_new_format	detects Czech ID card in new format	no	
Func_dea_number	detects DEA number	yes	
Func_denmark_eu_tax_file_number	detects Denmark personal identification number	no	
Func_district_of_columbia_drivers_license_number	detects District of Columbia driver's license number	no	
Func_estonia_eu_national_id_card	detects Estonia Personal Identification Code	no	
Func_eu_debit_card	detects EU debit card	no	
Func_finnish_national_id	detects Finnish national ID	no	
Func_florida_drivers_license_number	detects Florida driver's license number	no	
Func_florida_maryland_michigan_minnesota_drivers_license_number	detects Florida, Maryland, Michigan, Minnesota driver's license number	no	
Func_formatted_itin	detects formatted US ITIN	yes	
Func_fr_insee	detects France INSEE	no	
Func_fr_passport	detects France passport	no	
Func_france_eu_tax_file_number	detects France tax file number	no	
Func_france_value_added_tax_number	detects France value added tax number	no	
Func_french_drivers_license	detects French driver's license	no	
Func_french_insee	detects French INSEE	no	
Func_georgia_drivers_license_number	detects Georgia driver's license number	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_german_drivers_license	detects Germany driver's license	no	
Func_german_passport	detects Germany passport	no	
Func_german_passport_data	detects Germany passport	no	
Func_germany_eu_tax_file_number	detects Germany tax file number	no	
Func_germany_value_added_tax_number	detects Germany value added tax number	no	
Func_greece_eu_ssn	detects Greece sin (AMKA)	no	
Func_hawaii_drivers_license_number	detects Hawaii driver's license number	no	
Func_hong_kong_id_card	detects Hong Kong ID card	no	
Func_hungarian_value_added_tax_number	detects Hungary value added tax number	no	
Func_hungary_eu_national_id_card	detects Hungary personal identification number	no	
Func_hungary_eu_ssn_or_equivalent	detects Hungary social security number	no	
Func_hungary_eu_tax_file_number	detects Hungary tax file number	no	
Func_iban	detects IBAN	yes	
Func_idaho_drivers_license_number	detects Idaho driver's license number	no	
Func_illinois_drivers_license_number	detects Illinois driver's license number	no	
Func_india_aadhaar	detects India aadhaar	yes	
Func_indiana_drivers_license_number	detects Indiana driver's license number	no	
Func_iowa_drivers_license_number	detects Iowa driver's license number	no	
Func_ireland_pps	detects Ireland PPS	no	
Func_israeli_national_id_number	detects Israel national ID number	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_italy_eu_national_id_card	detects Italy fiscal code	no	
Func_italy_value_added_tax_number	detects Italy value added tax number	no	
Func_japanese_my_number_corporate	detects Japan my number corporate	yes	
Func_japanese_my_number_personal	detects Japan my number personal	yes	
Func_jp_bank_account	detects Japan bank account	no	
Func_jp_bank_account_branch_code	detects Japan bank account branch code	no	
Func_jp_drivers_license_number	detects Japan driver's license number	no	
Func_jp_passport	detects Japan passport	no	
Func_jp_resident_registration_number	detects Japan-resident registration number	no	
Func_jp_sin	detects Japan SIN	no	
Func_jp_sin_pre_1997	detects Japan sin pre 1997	no	
Func_kansas_drivers_license_number	detects Kansas driver's license number	no	
Func_kentucky_drivers_license_number	detects Kentucky driver's license number	no	
Func_kentucky_massachusetts_virginia_drivers_license_number	detects Kentucky, Massachusetts, Virginia driver's license number	no	
Func_latvia_eu_national_id_card	detects Latvia personal code	no	
Func_lithuania_eu_tax_file_number	detects Lithuania personal code	no	
Func_louisiana_drivers_license_number	detects Louisiana driver's license number	no	
Func_luxemburg_eu_tax_file_number	detects Luxemburg national identification number (natural persons)	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_luxemburg_eu_tax_file_number_non_natural	detects Luxemburg national identification number (non-natural persons)	no	
Func_maine_drivers_license_number	detects Maine driver's license number	no	
Func_manitoba_drivers_license_number	detects Manitoba driver's license number	no	
Func_maryland_drivers_license_number	detects Maryland driver's license number	no	
Func_massachusetts_drivers_license_number	detects Massachusetts driver's license number	no	
Func_mexico_population_registry_code	detects Mexico population registry code	no	
Func_michigan_minnesota_drivers_license_number	detects Michigan, Minnesota driver's license number	no	
Func_minnesota_drivers_license_number	detects Minnesota driver's license number	no	
Func_mississippi_oklahoma_drivers_license_number	detects Mississippi, Oklahoma driver's license number	no	
Func_missouri_drivers_license_number	detects Missouri driver's license number	no	
Func_montana_drivers_license_number	detects Montana driver's license number	no	
Func_nebraska_drivers_license_number	detects Nebraska driver's license number	no	
Func_netherlands_bsn	detects Netherlands BSN	no	
Func_netherlands_eu_tax_file_number	detects Netherlands tax file number	no	
Func_netherlands_value_added_tax_number	detects Netherlands value added tax number	no	
Func_nevada_drivers_license_number	detects Nevada driver's license number	no	
Func_new_brunswick_drivers_license_number	detects New Brunswick driver's license number	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_new_hampshire_drivers_license_number	detects New Hampshire driver's license number	no	
Func_new_jersey_drivers_license_number	detects New Jersey driver's license number	no	
Func_new_mexico_drivers_license_number	detects New Mexico driver's license number	no	
Func_new_york_drivers_license_number	detects New York driver's license number	no	
Func_new_zealand_bank_account_number	detects New Zealand bank account number	no	
Func_new_zealand_inland_revenue_number	detects New Zealand inland revenue number	no	
Func_new_zealand_ministry_of_health_number	detects New Zealand ministry of health number	no	
Func_newfoundland_labrador_drivers_license_number	detects Newfoundland Labrador driver's license number	no	
Func_newzealand_driver_license_number	detects New Zealand driver license number	no	
Func_newzealand_social_welfare_number	detects New Zealand social welfare number	no	
Func_north_carolina_drivers_license_number	detects North Carolina driver's license number	no	
Func_north_dakota_drivers_license_number	detects North Dakota driver's license number	no	
Func_norway_id_number	detects Norway ID number	no	
Func_nova_scotia_drivers_license_number	detects Nova Scotia driver's license number	no	
Func_ohio_drivers_license_number	detects Ohio driver's license number	no	
Func_ontario_drivers_license_number	detects Ontario driver's license number	no	
Func_pennsylvania_drivers_license_number	detects Pennsylvania driver's license number	no	
Func_pesel_identification_number	detects Poland National ID (PESEL)	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_poland_eu_tax_file_number	detects Poland tax file number	no	
Func_polish_national_id	detects Poland identity card	no	
Func_polish_passport_number	detects Polish passport number	no	
Func_polish_regon_number	detects Polish REGON number	no	
Func_portugal_eu_tax_file_number	detects Portugal Tax Identification Number	no	
Func_prince_edward_island_drivers_license_number	detects Prince Edward Island driver's license number	no	
Func_quebec_drivers_license_number	detects Quebec driver's license number	no	
Func_randomized_formatted_ssn	detects randomized formatted US SSN	yes	
Func_randomized_unformatted_ssn	detects randomized unformatted US SSN	yes	
Func_rhode_island_drivers_license_number	detects Rhode Island driver's license number	no	
Func_romania_eu_national_id_card	detects Romania personal numeric code (CNP)	no	
Func_saskatchewan_drivers_license_number	detects Saskatchewan driver's license number	no	
Func_slovakia_eu_national_id_card	detects Slovakia personal number	no	
Func_slovenia_eu_national_id_card	detects Slovenia Unique Master Citizen Number	no	
Func_slovenia_eu_tax_file_number	detects Slovenia tax file number	no	
Func_south_africa_identification_number	detects South Africa identification number	yes	
Func_south_carolina_drivers_license_number	detects South Carolina driver's license number	no	
Func_south_dakota_drivers_license_number	detects South Dakota driver's license number	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_south_korea_resident_number	detects South Korea resident number	no	
Func_spain_eu_DL_and_NI_number_citizen	detects Spain DL and NI number citizen	no	
Func_spain_eu_DL_and_NI_number_foreigner	detects Spain DL and NI number foreigner	no	
Func_spain_eu_driver's_license_number	detects Spain driver's license number	no	
Func_spain_eu_tax_file_number	detects Spain tax file number	no	
Func_spanish_social_security_number	detects Spanish social security number	no	
Func_ssn	Function to detect non-randomized formatted US SSN	yes	
Func_sweden_eu_tax_file_number	detects Sweden tax file number	no	
Func_swedish_national_identifier	detects Swedish national identifier	yes	
Func_swiss_social_security_number_ahv	detects Swiss social security number AHV	no	
Func_taiwanese_national_id	detects Taiwanese national ID	no	
Func_tennessee_drivers_license_number	detects Tennessee driver's license number	no	
Func_texas_drivers_license_number	detects Texas driver's license number	no	
Func_Thai_Citizen_Id	detects Thai Citizen ID	no	
Func_Turkish_National_Id	detects Turkish National ID	yes	
Func_uk_drivers_license	detects UK driver's license	no	
Func_uk_eu_tax_file_number	detects UK unique taxpayer number	no	
Func_uk_nhs_number	detects UK NHS number	yes	
Func_uk_nino	detects UK NINO	no	

FUNCTION NAME	FUNCTION ACTION	IS A VALIDATOR	
Func_unformatted_canadian_sin	detects unformatted Canadian SIN	no	
Func_unformatted_itin	detects unformatted US ITIN	yes	
Func_unformatted_ssn	detects non-randomized unformatted US SSN	yes	
Func_usa_uk_passport	detects USA and UK passport	yes	
Func_utah_drivers_license_number	detects Utah driver's license number	no	
Func_vermont_drivers_license_number	detects Vermont driver's license number	no	
Func_virginia_drivers_license_number	detects Virginia driver's license number	no	
Func_washington_drivers_license_number	detects Washington driver's license number	no	
Func_west_virginia_drivers_license_number	detects West Virginia driver's license number	no	
Func_wisconsin_drivers_license_number	detects Wisconsin driver's license number	no	
Func_wyoming_drivers_license_number	detects Wyoming driver's license number	no	

Func_us_date

Func_us_date looks for dates in common U.S. formats. The common formats are "month/day/year", "month-day-year", and "month day year ". The names or abbreviations of months aren't case-sensitive.

Examples:

- December 2, 2016
- Dec 2, 2016
- dec 02 2016
- 12/2/2016
- 12/02/16
- Dec-2-2016
- 12-2-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.

Func_eu_date

Fund_eu_dates looks for dates in common E.U. formats (and most places outside the U.S.), such as "day/month/year", "day-month-year", and "day month year". The names or abbreviations of months aren't case-sensitive.

Examples:

- 2 Dec 2016
- 02 dec 2016
- 2 Dec 16
- 2/12/2016
- 02/12/16
- 2-Dec-2016
- 2-12-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.
- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept oct okt nov dec
- French
  - janvier, février, mars, avril, mai, juin juillet, août, septembre, octobre, novembre, décembre
  - janv. févr. mars avril mai juin juil. août sept. oct. nov. déc.
- German
  - jänuar, februar, märz, April, mai, juni juli, August, September, oktober, November, dezember
  - Jan./Jän. Feb. März Apr. Mai Juni Juli Aug. Sept. Okt. Nov. Dez.
- Italian
  - gennaio, febbraio, marzo, aprile, maggio, giugno, luglio, agosto, settembre, ottobre, novembre, dicembre
  - genn. febbr. mar. apr. magg. giugno luglio ag. sett. ott. nov. dic.
- Portuguese

    - janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
    - jan fev mar abr mai jun jul ago set out nov dez
- Spanish
    - enero, febrero, marzo, abril, mayo, junio, julio, agosto, septiembre, octubre, noviembre, diciembre
    - enero feb. marzo abr. mayo jun. jul. agosto sept./set. oct. nov. dic.

Func_eu_date1 (deprecated)

> **NOTE**
> This function is deprecated because it supports only Portuguese month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Portuguese. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Dez 2016
- 02 dez 2016
- 2 Dez 16
- 2/12/2016
- 02/12/16
- 2-Dez-2016
- 2-12-16

Accepted month names:

- Portuguese
    - janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
    - jan fev mar abr mai jun jul ago set out nov dez

Func_eu_date2 (deprecated)

> **NOTE**
> This function is deprecated because it supports only Dutch month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Dutch. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Mei 2016

- 02 mei 2016
- 2 Mei 16
- 2/12/2016
- 02/12/16
- 2-Mei-2016
- 2-12-16

Accepted month names:

- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept out okt nov dec

Func_expiration_date

Func_expiration_date looks for dates that are in formats commonly used by credit and debit cards. This function will match dates in format of "month/year", "month-year", "[month name] year", and "[month abbreviation] year". The names or abbreviations of months aren't case-sensitive.

Examples:

- MM/YY -- for example, 01/11 or 1/11
- MM/YYYY -- for example, 01/2011 or 1/2011
- MM-YY -- for example, 01-22 or 1-11
- MM-YYYY -- for example, 01-2000 or 1-2000

The following formats support YY or YYYY:

- Month-YYYY -- for example Jan-2010 or january-2010 or Jan-10 or january-10
- Month YYYY -- for example, 'january 2010' or 'Jan 2010' or 'january 10' or 'Jan 10'
- MonthYYYY -- for example, 'january2010' or 'Jan2010' or 'january10' or 'Jan10'
- Month/YYYY -- for example, 'january/2010' or 'Jan/2010' or 'january/10' or 'Jan/10'

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan Feb Mar Apr May June July Aug Sept Oct Nov Dec

Func_us_address

Func_us_address looks for a U.S. state name or postal abbreviation followed by a valid zip code. The zip code must be one of the correct zip codes associated with the U.S. state name or abbreviation. The U.S. state name and zip code cannot be separated by punctuation or letters.

Examples:

- Washington 98052
- Washington 98052-9998
- WA 98052
- WA 98052-9998

Learn about trainable classifiers

2/18/2021 • 5 minutes to read • Edit Online

Classifying and labeling content so it can be protected and handled properly is the starting place for the information protection discipline. Microsoft 365 has three ways to classify content.

Manually

This method requires human judgment and action. An admin may either use the pre-existing labels and sensitive information types or create their own and then publish them. Users and admins apply them to content as they encounter it. You can then protect the content and manage its disposition.

Automated pattern matching

This category of classification mechanisms include finding content by:

- Keywords or metadata values (keyword query language).
- Using previously identified patterns of sensitive information like social security, credit card or bank account numbers (Sensitive information type entity definitions).
- Recognizing an item because it's a variation on a template (document finger printing).
- Using the presence of exact strings (exact data match).

Sensitivity and retention labels can then be automatically applied to make the content available for use in data loss prevention (DLP) and auto-apply polices for retention labels.

Classifiers

This classification method is particularly well suited to content that isn't easily identified by either the manual or automated pattern matching methods. This method of classification is more about training a classifier to identify an item based on what the item is, not by elements that are in the item (pattern matching). A classifier learns how to identify a type of content by looking at hundreds of examples of the content you're interested in classifying. You start by feeding it examples that are definitely in the category. Once it processes those, you test it by giving it a mix of both matching and non-matching examples. The classifier then makes predictions as to whether any given item falls into the category you're building. You then confirm its results, sorting out the true positives, true negatives, false positives, and false negatives to help increase the accuracy of its predictions.

When you publish the classifier, it sorts through items in locations like SharePoint Online, Exchange, and OneDrive, and classifies the content. After you publish the classifier, you can continue to train it using a feedback process that is similar to the initial training process.

Where you can use trainable classifiers

Both built-in classifiers and trainable classifiers are available as a condition for Office autolabeling with sensitivity labels, auto-apply retention label policy based on a condition and in communication compliance.

Sensitivity labels can use classifiers as conditions, see Apply a sensitivity label to content automatically.

> **IMPORTANT**
> Classifiers only work with items that are not encrypted and are in English.

Types of classifiers

- **pre-trained classifiers** - Microsoft has created and pre-trained a number of classifiers that you can start using without training them. These classifiers will appear with the status of `Ready to use`.
- **custom classifiers** - If you have classification needs that extend beyond what the pre-trained classifiers cover, you can create and train your own classifiers.

Pre-trained classifiers

Microsoft 365 comes with five pre-trained classifiers:

Caution

We are deprecating the **Offensive Language** pre-trained classifier because it has been producing a high number of false positives. Don't use it and if you are currently using it, you should move your business processes off of it. We recommend using the **Threat**, **Profanity**, and **Harassment** pre-trained classifiers instead.

- **Resumes**: detects items that are textual accounts of an applicant's personal, educational, professional qualifications, work experience, and other personally identifying information
- **Source Code**: detects items that contain a set of instructions and statements written in the top 25 used computer programming languages on GitHub
  - ActionScript
  - C
  - C#
  - C++
  - Clojure
  - CoffeeScript
  - Go
  - Haskell
  - Java
  - JavaScript
  - Lua
  - MATLAB
  - Objective-C
  - Perl
  - PHP
  - Python
  - R
  - Ruby
  - Scala
  - Shell
  - Swift
  - Tex
  - Vim Script

> **NOTE**
> Source Code is trained to detect when the bulk of the text is source code. It does not detect source code text that is interspersed with plain text.

- **Harassment**: detects a specific category of offensive language text items related to offensive conduct

targeting one or multiple individuals based on the following traits: race, ethnicity, religion, national origin, gender, sexual orientation, age, disability

- **Profanity**: detects a specific category of offensive language text items that contain expressions that embarrass most people
- **Threat**: detects a specific category of offensive language text items related to threats to commit violence or do physical harm or damage to a person or property

These appear in the **Microsoft 365 compliance center** > **Data classification** > **Trainable classifiers** view with the status of `Ready to use`.

> **IMPORTANT**
> Please note that the offensive language, harassment, profanity, and threat classifiers only work with searchable text are not exhaustive or complete. Further, language and cultural standards continually change, and in light of these realities, Microsoft reserves the right to update these classifiers in its discretion. While the classifiers may assist your organization in monitoring offensive and other language used, the classifiers do not address consequences of such language and are not intended to provide your organization's sole means of monitoring or responding to the use of such language. Your organization, and not Microsoft or its subsidiaries, remains responsible for all decisions related to monitoring, enforcement, blocking, removal and retention of any content identified by a pre-trained classifier.

Custom classifiers

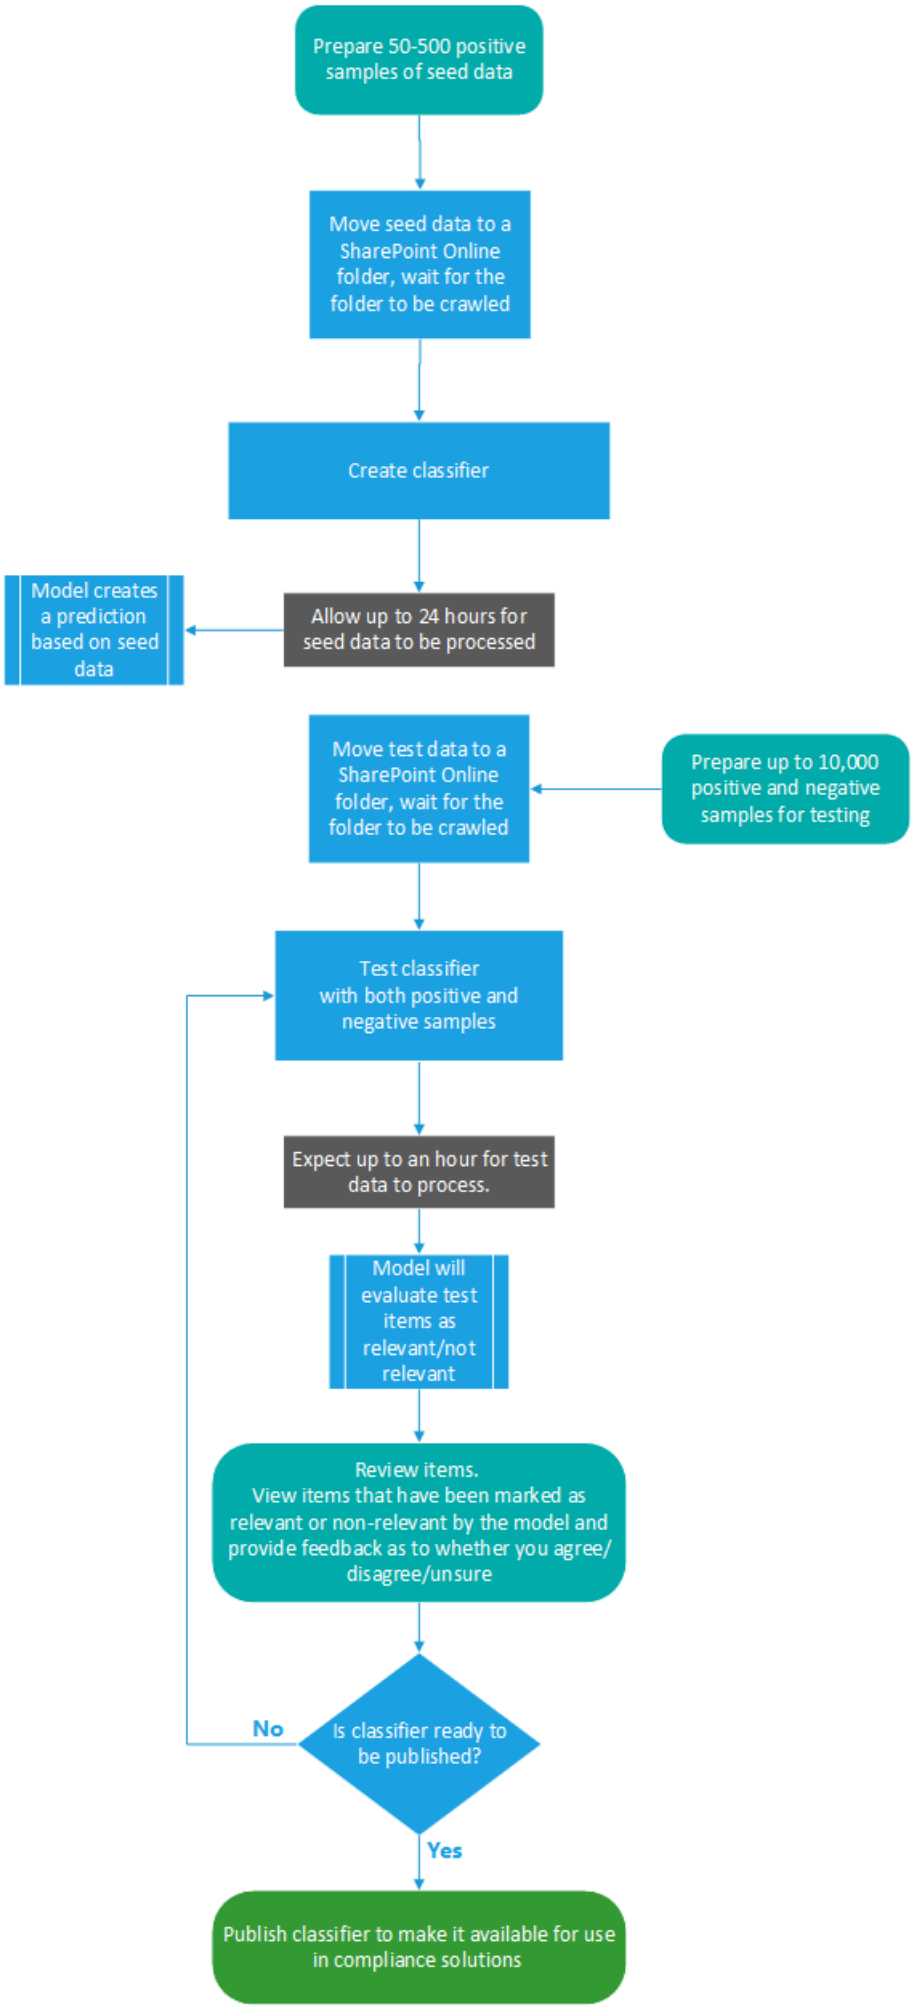
When the pre-trained classifiers don't meet your needs, you can create and train your own classifiers. There's significantly more work involved with creating your own, but they'll be much better tailored to your organizations needs.

For example you could create trainable classifiers for:

- Legal documents - such as attorney client privilege, closing sets, statement of work
- Strategic business documents - like press releases, merger and acquisition, deals, business or marketing plans, intellectual property, patents, design docs
- Pricing information - like invoices, price quotes, work orders, bidding documents
- Financial information - such as organizational investments, quarterly or annual results

Process flow for creating custom classifiers

Creating and publishing a classifier for use in compliance solutions, such as retention policies and communication supervision, follows this flow. For more detail on creating a custom trainable classifier see, Creating a custom classifier.



Retraining classifiers

You can help improve the accuracy of all custom classifiers and some pre-trained classifiers by providing them with feedback on the accuracy of the classification that they perform. This is called retraining and follow this workflow.

Get started with trainable classifiers

2/18/2021 • 6 minutes to read • Edit Online

A Microsoft 365 trainable classifier is a tool you can train to recognize various types of content by giving it samples to look at. Once trained, you can use it to identify item for application of Office sensitivity labels, Communications compliance policies, and retention label policies.

Creating a custom trainable classifier first involves giving it samples that are human picked and positively match the category. Then, after it has processed those, you test the classifiers ability to predict by giving it a mix of positive and negative samples. This article shows you how to create and train a custom classifier and how to improve the performance of custom trainable classifiers and pre-trained classifiers over their lifetime through retraining.

To learn more about the different types of classifiers, see Learn about trainable classifiers.

Prerequisites

Licensing requirements

Classifiers are a Microsoft 365 E5, or E5 Compliance feature. You must have one of these subscriptions to make use of them.

Permissions

To access classifiers in the UI:

- the Global admin needs to opt in for the tenant to create custom classifiers.
- Compliance Administrator role is required to train a classifier.

You'll need accounts with these permissions to use classifiers in these scenarios:

- Retention label policy scenario: Record Management and Retention Management roles
- Sensitivity label policy scenario: Security Administrator, Compliance Administrator, Compliance Data Administrator
- Communication compliance policy scenario: Insider Risk Management Admin, Supervisory Review Administrator

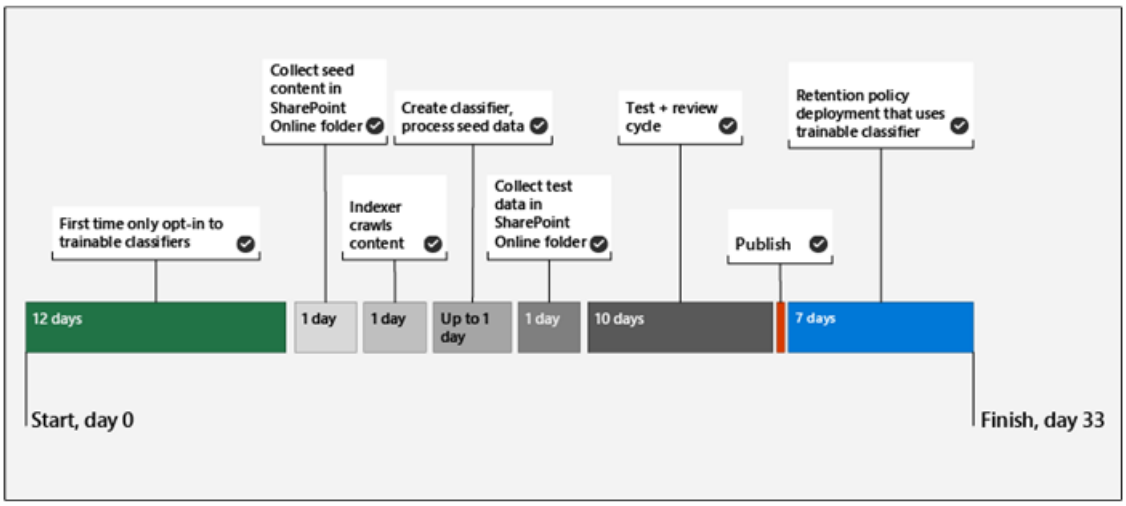
> **IMPORTANT**
> By default, only the user who creates a custom classifier can train and review predictions made by that classifier.

Prepare for a custom trainable classifier

It's helpful to understand what's involved in creating a custom trainable classifier before you dive in.

Timeline

This timeline reflects a sample deployment of trainable classifiers.



TIP

Opt-in is required the first time for trainable classifiers. It takes twelve days for Microsoft 365 to complete a baseline evaluation of your organizations content. Contact your global administrator to kick off the opt-in process.

Overall workflow

To understand more about the overall workflow of creating custom trainable classifiers, see Process flow for creating customer trainable classifiers.

Seed content

When you want a trainable classifier to independently and accurately identify an item as being in particular category of content, you first have to present it with many samples of the type of content that are in the category. This feeding of samples to the trainable classifier is known as *seeding*. Seed content is selected by a human and is judged to represent the category of content.

TIP

You need to have at least 50 positive samples and as many as 500. The trainable classifier will process up to the 500 most recent created samples (by file created date/time stamp). The more samples you provide, the more accurate the predictions the classifier will make.

Testing content

Once the trainable classifier has processed enough positive samples to build a prediction model, you need to test the predictions it makes to see if the classifier can correctly distinguish between items that match the category and items that don't. You do this by selecting another, hopefully larger, set of human picked content that consists of samples that should fall into the category and samples that won't. You should test with different data than the initial seed data you first provided. Once it processes those, you manually go through the results and verify whether each prediction is correct, incorrect, or you aren't sure. The trainable classifier uses this feedback to improve its prediction model.

TIP

For best results, have at least 200 items in your test sample set with an even distribution of positive and negative matches.

How to create a trainable classifier

1. Collect between 50-500 seed content items. These must be only samples that strongly represent the type of content you want the trainable classifier to positively identify as being in the classification category. See, Default crawled file name extensions and parsed file types in SharePoint Server for the supported file types.

   > **IMPORTANT**
   > The seed and test sample items must not be encrypted and they must be in English.

   > **IMPORTANT**
   > Make sure the items in your seed set are **strong** examples of the category. The trainable classifier initially builds its model based on what you seed it with. The classifier assumes all seed samples are strong positives and has no way of knowing if a sample is a weak or negative match to the category.

2. Place the seed content in a SharePoint Online folder that is dedicated to holding *the seed content only*. Make note of the site, library, and folder URL.

   > **TIP**
   > If you create a new site and folder for your seed data, allow at least an hour for that location to be indexed before creating the trainable classifier that will use that seed data.

3. Sign in to Microsoft 365 compliance center with compliance admin or security admin role access and open **Microsoft 365 compliance center** or **Microsoft 365 security center** > **Data classification**.
4. Choose the **Trainable classifiers** tab.
5. Choose **Create trainable classifier**.
6. Fill in appropriate values for the `Name` and `Description` fields of the category of items you want this trainable classifier to identify.
7. Pick the SharePoint Online site, library, and folder URL for the seed content site from step 2. Choose `Add`.
8. Review the settings and choose `Create trainable classifier`.
9. Within 24 hours the trainable classifier will process the seed data and build a prediction model. The classifier status is `In progress` while it processes the seed data. When the classifier is finished processing the seed data, the status changes to `Need test items`.
10. You can now view the details page by choosing the classifier.

Training process

Add items to test the classifier

Step	Items	Status
Add items to test the classifier	-	Ready to test
Review items to improve the classifier accuracy	-	Not available
Publish the classifier	-	Not available

Add items to test

11. Collect at least 200 test content items (10,000 max) for best results. These should be a mix of items that are strong positives, strong negatives and some that are a little less obvious in their nature. See, Default crawled file name extensions and parsed file types in SharePoint Server for the supported file types.

    IMPORTANT
    The sample items must not be encrypted and they must be in English.

12. Place the test content in a SharePoint Online folder that is dedicated to holding *the test content only*. Make note of the SharePoint Online site, library, and folder URL.

    TIP
    If you create a new site and folder for your test data, allow at least an hour for that location to be indexed before creating the trainable classifier that will use that seed data.

13. Choose `Add items to test`.
14. Pick the SharePoint Online site, library, and folder URL for the test content site from step 12. Choose `Add` .
15. Finish the wizard by choosing `Done`. Your trainable classifier will take up to an hour to process the test files.
16. When the trainable classifier is done processing your test files, the status on the details page will change to `Ready to review`. If you need to increase the test sample size, choose `Add items to test` and allow the trainable classifier to process the additional items.

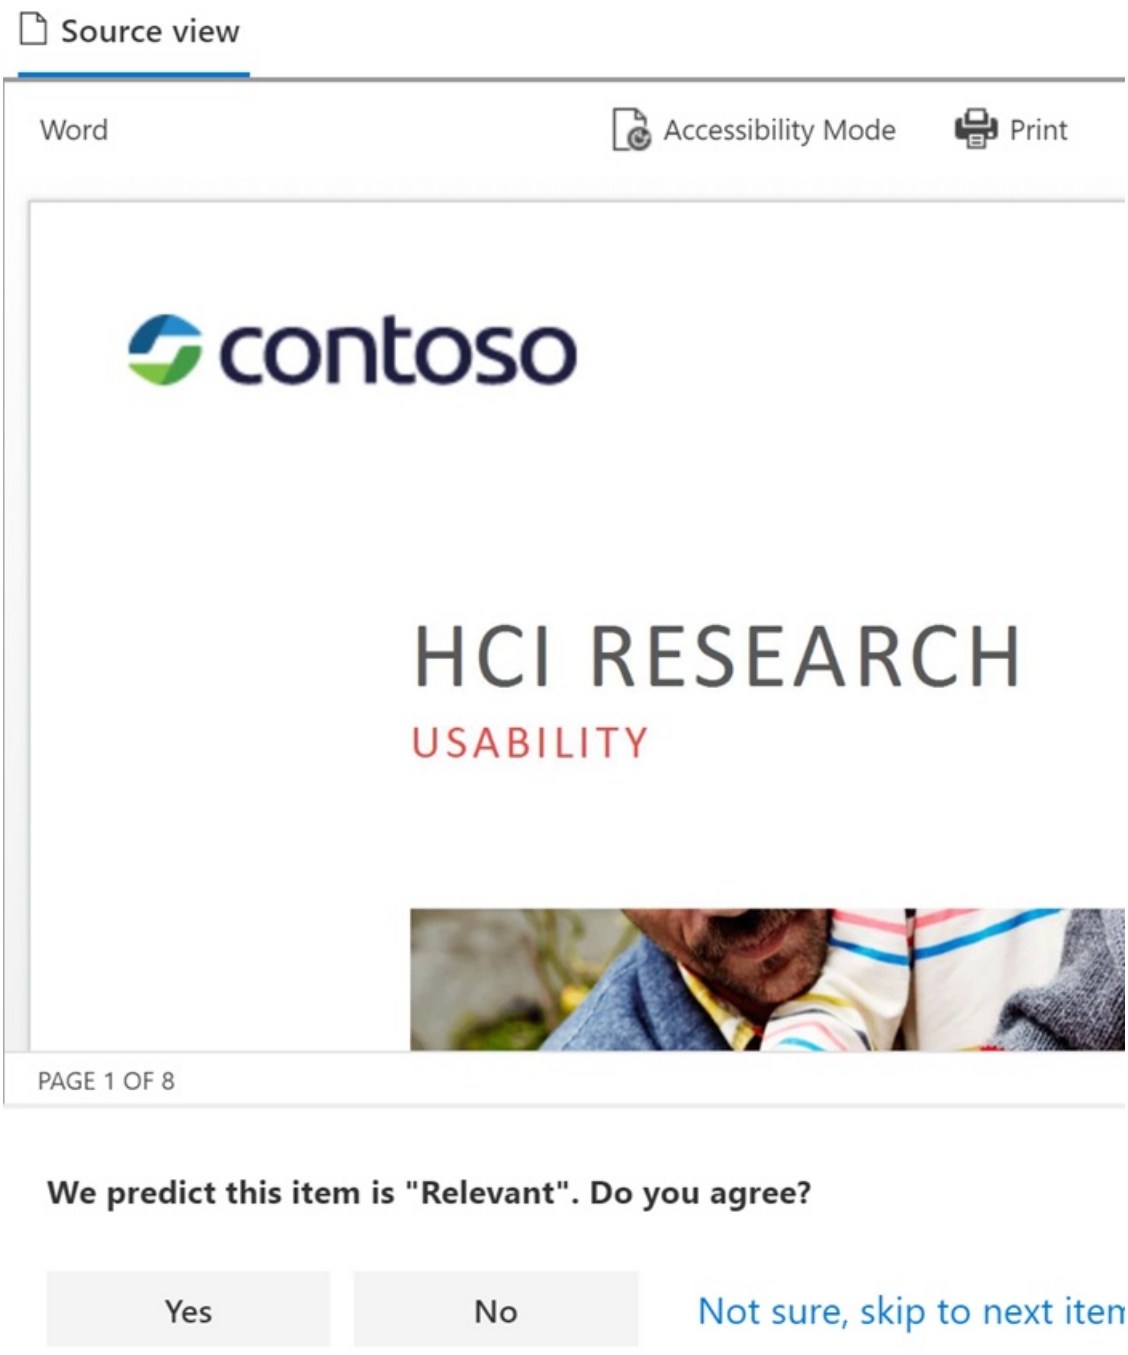
Training process

Review items to generate classifier accuracy

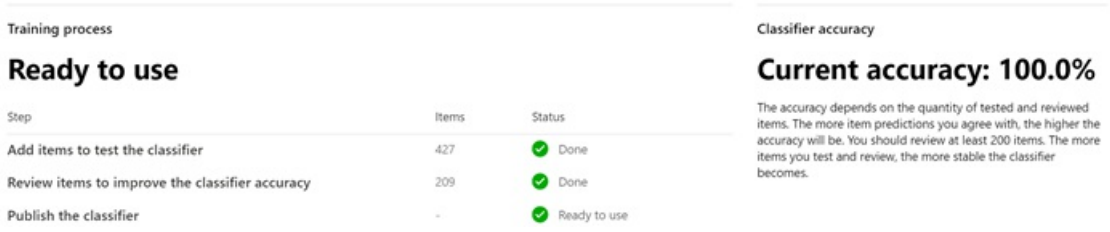
Step	Items	Status
Add items to test the classifier	24	In progress
Review items to improve the classifier accuracy	0	Ready to review
Publish the classifier	-	Not available

17. Choose `Tested items to review` tab to review items.

18. Microsoft 365 will present 30 items at a time. Review them and in the `We predict this item is "Relevant". Do you agree?` box choose either `Yes` or `No` or `Not sure, skip to next item`. Model accuracy is automatically updated after every 30 items.



19. Review *at least* 200 items. Once the accuracy score has stabilized, the **publish** option will become available and the classifier status will say `Ready to use`.



20. Publish the classifier.

21. Once published your classifier will be available as a condition in Office auto-labeling with sensitivity labels, auto-apply retention label policy based on a condition and in Communication compliance.

How to retrain a classifier in communications compliance

2/18/2021 • 3 minutes to read • Edit Online

A Microsoft 365 trainable classifier is a tool you can train to recognize various types of content by giving it samples to look at. Once trained, you can use it to identify item for application of Office sensitivity labels, communications compliance policies, and retention label policies.

This article shows you how to improve the performance of custom trainable classifiers and some pre-trained classifiers by providing them additional feedback.

To learn more about the different types of classifiers, see Learn about trainable classifiers.

Permissions

To access classifiers in the Microsoft 365 Compliance center:

- the Compliance admin role or Compliance Data Administrator is required to train a classifier

You'll need accounts with these permissions to use classifiers in these scenarios:

- Communication compliance policy scenario: Insider Risk Management Admin, Supervisory Review Administrator

Overall workflow

> **IMPORTANT**
>
> You provide feedback in the compliance solution that is using the classifier as a condition. **If you don't have a communications compliance policy that uses a classifier as a condition, stop here.**

As you use your classifiers, you may want to increase the precision of the classifications that they're making. You do this by evaluating the quality of the classifications made for items it has identified as being a match or not a match. After you make 30 evaluations for a classifier it takes that feedback and automatically retrains itself.

To understand more about the overall workflow of retraining a classifier, see Process flow for retraining a classifier.

> **NOTE**
>
> A classifier must already be published and in use before it can be retrained.

How to retrain a classifier in communication compliance policies

1. Open the Communication compliance policy that uses a classifier as a condition and choose one of the identified items from the **Pending** list.
2. Choose the ellipsis and **Improve classification**.
3. In the **Detailed feedback** pane, if the item is a true positive, choose, **Match**. If the item is a false positive, that is it was incorrectly included in the category, choose **Not a match**.

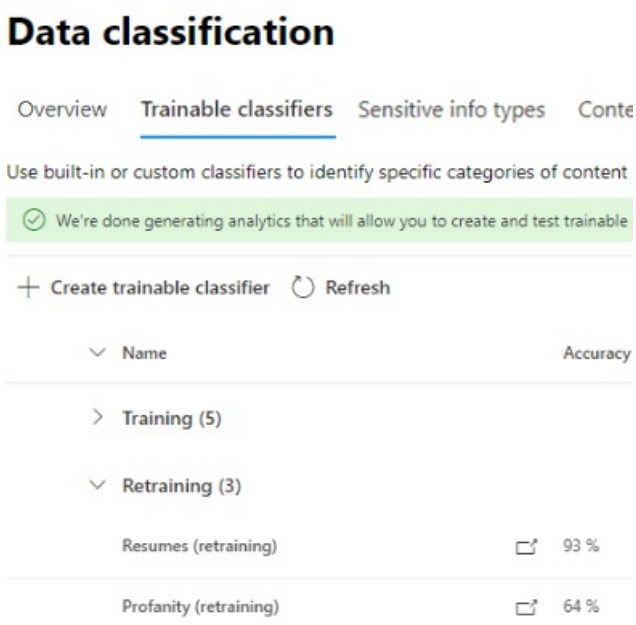
4. If there is another classifier that would be more appropriate for the item, you can choose it from the **Suggest other trainable classifiers** list. This will trigger the other classifier to evaluate the item.

> **TIP**
> You can provide feedback on multiple items simultaneously by choosing them all and then choosing **Provide detailed feedback** in the command bar.

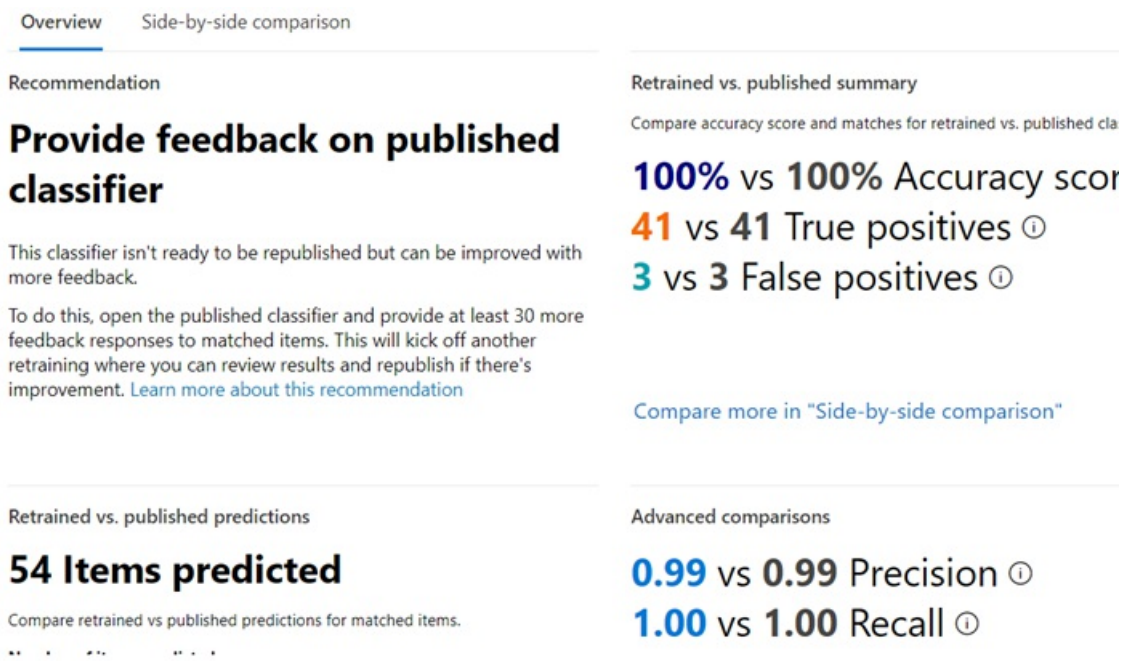
5. Choose **Send feedback** to send your evaluation of the `match`, `not a match` classifications and suggest other trainable classifiers. When you've provided 30 instances of feedback to a classifier, it will automatically retrain. Retraining can take from 1-4 hours. Classifiers can only be retrained twice per day.

> **IMPORTANT**
> This information goes to the classifier in your tenant, **it does not go back to Microsoft**.

6. Open the **Data classification** page in the **Microsoft 365 compliance center**.
7. Open **Trainable classifiers**.
8. The classifier that was used in your Communications compliance policy will appear under the **Re-training** heading.



9. Once retraining completes, choose the classifier to open the retraining overview.



10. Review the recommended action, and the prediction comparisons of the retrained and currently published versions of the classifier.
11. If you satisfied with the results of the retraining, choose **Re-publish**.
12. If you are not satisfied with the results of the retraining, you can choose to provide additional feedback to the classifier in the Communications compliance interface and start another retraining cycle or do nothing in which case the currently published version of the classifier will continue to be used.

Details on republishing recommendations

Here is a little information on how we formulate the recommendation to re-publish a retrained classifier or suggest further retraining. This requires a little deeper understanding of how trainable classifiers work.

After a retrain, we evaluate the classifier's performance on both the items with feedback as well as any items originally used to train the classifier.

- For built-in models, items used to train the classifier are the items used by Microsoft to build the model.
- For custom models, items used in the original training the classifier are from the sites you had added for test and review.

We compare the performance numbers on both sets of items for the retrained and published classifier to provide a recommendation on whether there was improvement to republish.

How to retrain a classifier in content explorer

2/18/2021 • 4 minutes to read • Edit Online

A Microsoft 365 trainable classifier is a tool you can train to recognize various types of content by giving it samples to look at. Once trained, you can use it to identify item for application of Office sensitivity labels, communications compliance policies, and retention label policies.

This article shows you how to improve the performance of custom trainable classifiers and some pre-trained classifiers by providing them additional feedback.

To learn more about the different types of classifiers, see Learn about trainable classifiers.

Permissions

To access classifiers in the Microsoft 365 Compliance center:

- the Compliance admin role or Compliance Data Administrator is required to train a classifier

You'll need accounts with these permissions to use classifiers in these scenarios:

- Retention label policy scenario: Record Management and Retention Management roles

Overall workflow

> **IMPORTANT**
> You provide feedback in content explorer for auto-apply retention label policies to Exchange items and uses the classifier as a condition. **If you don't have a retention policy that auto-applies a retention label to Exchange items and uses a classifier as a condition, stop here.**

As you use your classifiers, you may want to increase the precision of the classifications that they're making. You do this by evaluating the quality of the classifications made for items it has identified as being a match or not a match. After you make 30 evaluations for a classifier it takes that feedback and automatically retrains itself.

To understand more about the overall workflow of retraining a classifier, see Process flow for retraining a classifier.

> **NOTE**
> A classifier must already be published and in use before it can be retrained.

How to retrain a classifier in content explorer

1. Sign in to Microsoft 365 compliance center with compliance admin or security admin role access and open **Microsoft 365 compliance center** > **Data classification** > **Content explorer**.
2. Under the **Filter on labels, info types, or categories** list, expand **Trainable classifiers**.

> **IMPORTANT**
> It can take up to eight days for aggregated items to appear under the trainable classifiers heading.

3. Choose the trainable classifier you used in you auto-apply retention label policy. This is the trainable classifier you will give feedback on.

> **NOTE**
> If an item has an entry in the **Retention label** column, it means that the item was classified as a `match`. If an item doesn't have an entry in the **Retention label** column, it means it was classified as a `close match`. You can improve the classifier precision the most by providing feedback on `close match` items.

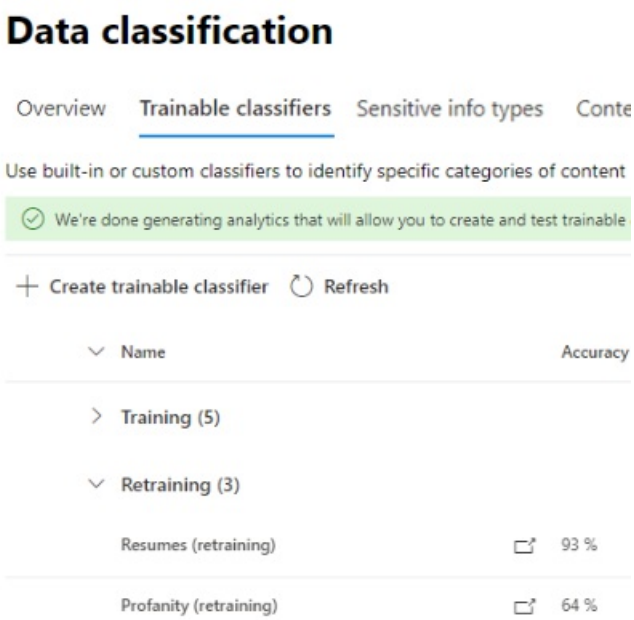
4. Choose an item and open it.

> **TIP**
> You can provide feedback on multiple items simultaneously by choosing them all and then choosing **Improve classification** in the command bar.

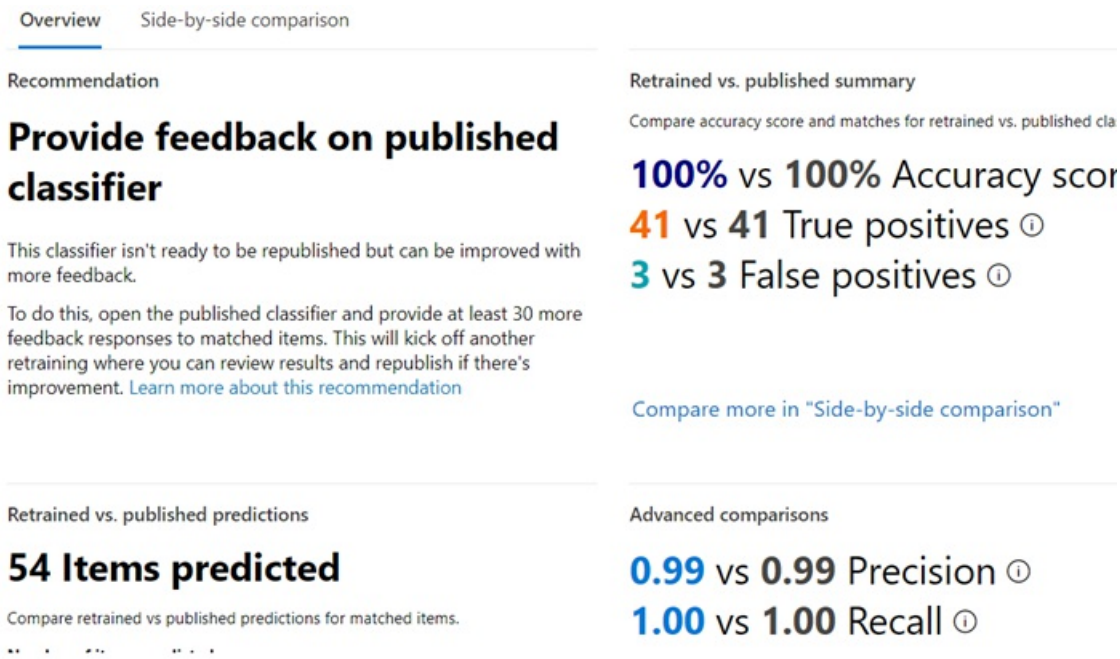
5. Choose **Provide feedback**.
6. In the **Detailed feedback** pane, if the item is a true positive, choose, **Match**. If the item is a false positive, that is it was incorrectly included in the category, choose **Not a match**.
7. If there is another classifier that would be more appropriate for the item, you can choose it from the **Suggest other trainable classifiers** list. This will trigger the other classifier to evaluate the item.
8. Choose **Send feedback** to send your evaluation of the `match`, `not a match` classifications and suggest other trainable classifiers. When you've provided 30 instances of feedback to a classifier, it will automatically retrain. Retraining can take from one to four hours. Classifiers can only be retrained twice per day.

> **IMPORTANT**
> This information goes to the classifier in your tenant, **it does not go back to Microsoft**.

9. Open **Trainable classifiers**.
10. The classifier that was used in your Communications compliance policy will appear under the **Re-training** heading.



11. Once retraining completes, choose the classifier to open the retraining overview.



12. Review the recommended action, and the prediction comparisons of the retrained and currently published versions of the classifier.
13. If you satisfied with the results of the retraining, choose **Re-publish**.
14. If you are not satisfied with the results of the retraining, you can choose to provide additional feedback to the classifier in the Communications compliance interface and start another retraining cycle or do nothing in which case the currently published version of the classifier will continue to be used.

Details on republishing recommendations

Here is a little information on how we formulate the recommendation to re-publish a retrained classifier or suggest further retraining. This requires a little deeper understanding of how trainable classifiers work.

After a retrain, we evaluate the classifier's performance on both the items with feedback as well as any items originally used to train the classifier.

Know your data - data classification overview

2/18/2021 • 5 minutes to read • Edit Online

As a Microsoft 365 administrator or compliance administrator, you can evaluate and then tag content in your organization in order to control where it goes, protect it no matter where it is and to ensure that it is preserved and deleted according to your organizations needs. You do this through the application of sensitivity labels, retention labels, and sensitive information type classification. There are various ways to do the discovery, evaluation and tagging, but the end result is that you may have very large number of documents and emails that are tagged and classified with one or both of these labels. After you apply your retention labels and sensitivity labels, you'll want to see how the labels are being used across your tenant and what is being done with those items. The data classification page provides visibility into that body of content, specifically:

- the number items that have been classified as a sensitive information type and what those classifications are
- the top applied sensitivity labels in both Microsoft 365 and Azure Information Protection
- the top applied retention labels
- a summary of activities that users are taking on your sensitive content
- the locations of your sensitive and retained data

You also manage these features on the data classification page:

- trainable classifiers
- sensitive information types

You can find data classification in the **Microsoft 365 compliance center** or **Microsoft 365 security center** > **Classification** > **Data Classification**.

Take a video tour of our data classification features.

Data classification will scan your sensitive content and labeled content before you create any policies. This is called **zero change management**. This lets you see the impact that all the retention and sensitivity labels are having in your environment and empower you to start assessing your protection and governance policy needs.

Prerequisites

A number of different subscriptions support Endpoint DLP. To see licensing options for Endpoint DLP see Information Protection licensing for guidance.

Permissions

In order to get access to the data classification page, an account must be assigned membership in any one of these roles or role groups.

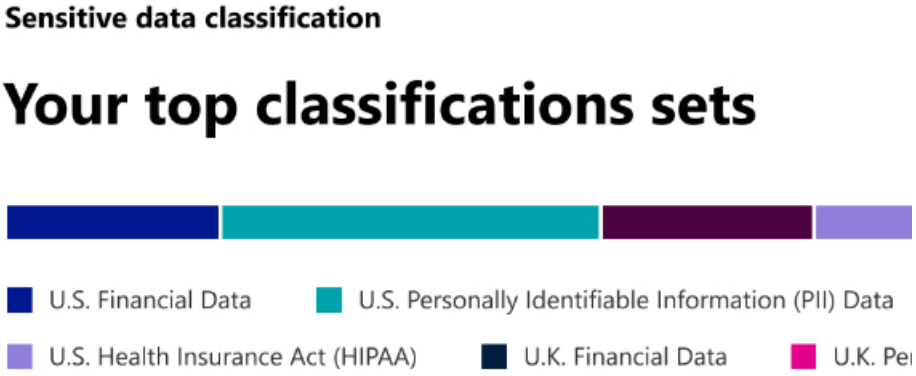
Microsoft 365 role groups

- Global administrator
- Compliance administrator
- Security administrator
- Compliance data administrator

Sensitive information types used most in your content

Microsoft 365 comes with many definitions of sensitive information types, such as an item containing a social security number or a credit card number. For more information on sensitive information types, see Sensitive information type entity definitions.

The sensitive information type card shows the top sensitive information types that have been found and labeled across your organization.



Explore data by industry regulators in the content explorer

To find out how many items are in any given classification category, hover over the bar for the category.

NOTE

If the card displays the message "No data found with sensitive information". It means that there are no items in your organization that have been classified as being a sensitive information type or no items that have been crawled. To get started with labels, see:

- Get started with sensitivity labels
- Get started with retention policies and retention labels
- Sensitive information type entity definitions

Top sensitivity labels applied to content

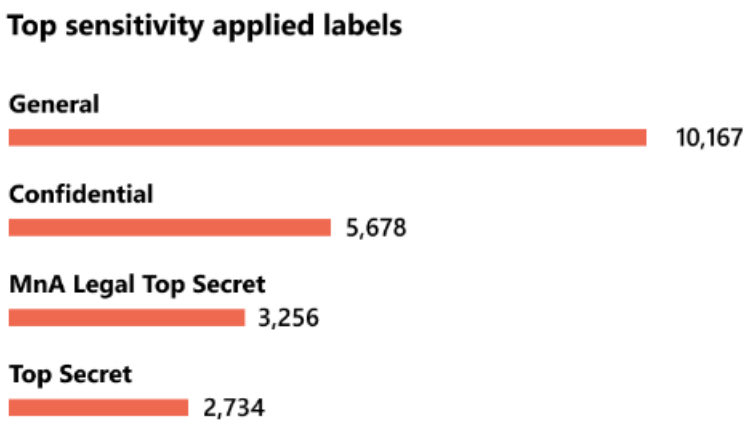
When you apply a sensitivity label to an item either through Microsoft 365 or Azure Information Protection (AIP), two things happen:

- a tag that indicates the value of the item to your org is embedded in the document and will follow it everywhere it goes
- the presence of the tag enables various protective behaviors, such as mandatory watermarking or encryption. With end point protection enabled you can even prevent an item from leaving your organizational control.

For more information on sensitivity labels, see: Learn about sensitivity labels

Sensitivity labels must be enabled for files that are in SharePoint and OneDrive in order for the corresponding data to surface in the data classification page. For more information, see Enable sensitivity labels for Office files in SharePoint and OneDrive.

The sensitivity label card shows the number of items (email or document) by sensitivity level.



NOTE

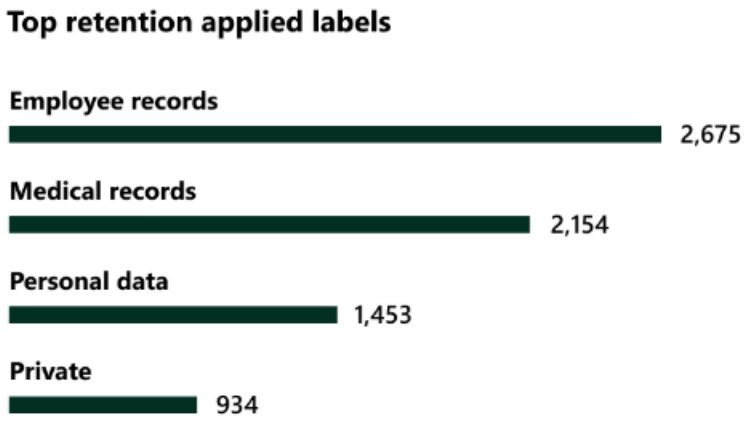
If you haven't created or published any sensitivity labels or no content has had a sensitivity label applied, this card will display the message "No sensitivity labels detected". To get started with sensitivity labels, see:

- Get started with sensitivity labels or for AIP Configure the Azure information protection policy

Top retention labels applied to content

Retention labels are used to manage the retention and disposition of content in your organization. When applied, they can be used to control how an item will be kept before deletion, whether it should be reviewed prior to deletion, when its retention period expires, and whether it should be marked as a record. For more information, see Learn about retention policies and retention labels.

The top applied retention labels card shows you how many items have a given retention label.



NOTE

If this card displays the message, "No retention labels detected", it means you haven't created or published any retention labels or no content has had a retention label applied. To get started with retention labels, see:

- Get started with retention policies and retention labels

Top activities detected

This card provides a quick summary of the most common actions that users are taking on the sensitivity labeled items. You can use the Activity explorer to drill deep down on eight different activities that Microsoft 365 tracks on labeled content and content that is located on Windows 10 endpoints.

> **NOTE**
>
> If this card displays the message, "No activity detected" it means that there's been no activity on the files or that user and admin auditing isn't turned on. To turn the audit logs on , see:
>
> - Search the audit log in security & compliance center

Sensitivity and retention labeled data by location

The point of the data classification reporting is to provide visibility into the number of items that have which label as well as their location. These cards let you know how many labeled items the are in Exchange, SharePoint, and OneDrive etc.

> **NOTE**
>
> If this card displays the message, "No locations detected, it means you haven't created or published any sensitivity labels or no content has had a retention label applied. To get started with sensitivity labels, see:
>
> - Sensitivity labels

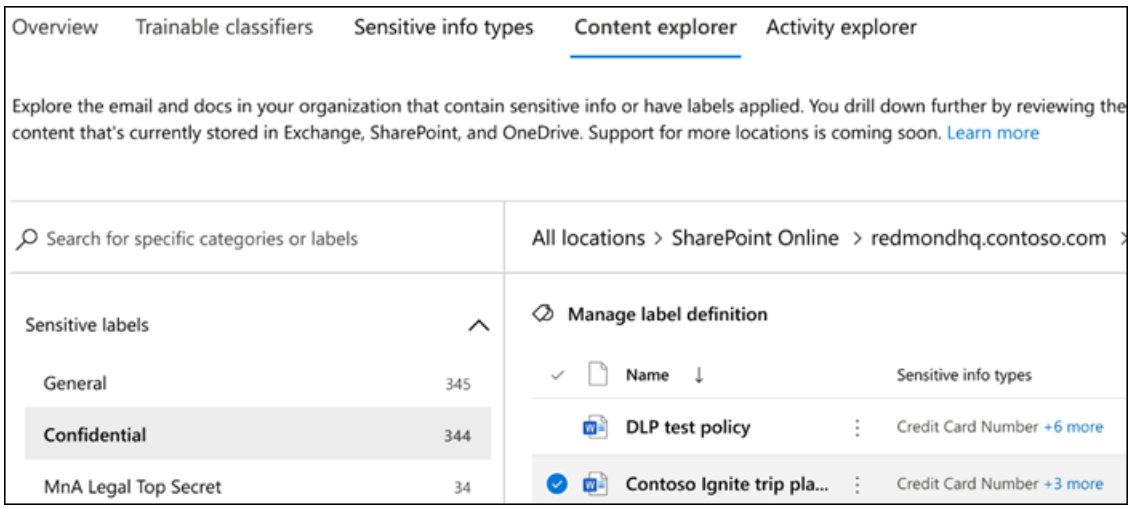
Get started with content explorer

2/18/2021 • 4 minutes to read • Edit Online

The data classification content explorer allows you to natively view the items that were summarized on the overview page.



Prerequisites

Every account that accesses and uses data classification must have a license assigned to it from one of these subscriptions:

- Microsoft 365 (E5)
- Office 365 (E5)
- Advanced Compliance (E5) add-on
- Advanced Threat Intelligence (E5) add-on
- Microsoft 365 E5/A5 Info Protection & Governance
- Microsoft 365 E5/A5 Compliance

Permissions

In order to get access to the content explorer tab, an account must be assigned membership in any one of these roles or role groups.

Microsoft 365 role groups

- Global administrator
- Compliance administrator
- Security administrator
- Compliance data administrator

> **IMPORTANT**
> Membership in these role groups does not allow you to view the list of items in content explorer or to view the contents of the items in content explorer.

Required permissions to access items in content explorer

Access to content explorer is highly restricted because it lets you read the contents of scanned files.

> **IMPORTANT**
> These permissions supercede permissions that are locally assigned to the items, which allows viewing of the content.

There are two roles that grant access to content explorer and it is granted using the Microsoft Security & Compliance Center:

- **Content Explorer List viewer**: Membership in this role group allows you to see each item and its location in list view. The `data classification list viewer` role has been pre-assigned to this role group.
- **Content Explorer Content viewer**: Membership in this role group allows you to view the contents of each item in the list. The `data classification content viewer` role has been pre-assigned to this role group.

The account you use to access content explorer must be in one or both of the role groups. These are independent role groups and are not cumulative. For example, if you want to grant an account the ability to view the items and their locations only, grant Content Explorer List viewer rights. If you want that same account to also be able to view the contents of the items in the list, grant Content Explorer Content viewer rights as well.

You can also assign either or both of the roles to a custom role group to tailor access to content explorer.

A Global admin, Compliance admin, or Data admin can assign the necessary Content Explorer List Viewer, and Content Explorer Content Viewer role group membership.

Content explorer

Content explorer shows a current snapshot of the items that have a sensitivity label, a retention label or have been classified as a sensitive information type in your organization.

Sensitive information types

A DLP policy can help protect sensitive information, which is defined as a **sensitive information type**. Microsoft 365 includes definitions for many common sensitive information types from across many different regions that are ready for you to use. For example, a credit card number, bank account numbers, national ID numbers, and Windows Live ID service numbers.

> **NOTE**
> Content explorer doesn't currently scan for sensitive information types in Exchange Online.

Sensitivity labels

A sensitivity label is simply a tag that indicates the value of the item to your organization. It can be applied manually, or automatically. Once applied it gets embedded in the document and will follow it everywhere it goes. A sensitivity label enables various protective behaviors, such as mandatory watermarking or encryption.

Sensitivity labels must be enabled for files that are in SharePoint and OneDrive in order for the corresponding data to surface in the data classification page. For more information, see Enable sensitivity labels for Office files in SharePoint and OneDrive.

Retention labels

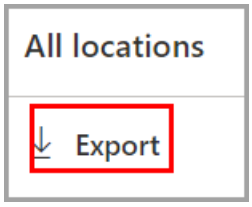
A retention label allows you to define how long a labeled item is kept and the steps to be taken prior to deleting it. They are applied manually or automatically via policies. They can play a role in helping your organization stay in compliance with legal and regulatory requirements.

How to use content explorer

1. Open **Microsoft 365 compliance center** > **Data classification** > **Content explorer**.
2. If you know the name of the label, or the sensitive information type, you can type that into the filter box.
3. Alternately, you can browse for the item by expanding the label type and selecting the label from the list.
4. Select a location under **All locations** and drill down the folder structure to the item.
5. Double-click to open the item natively in content explorer.

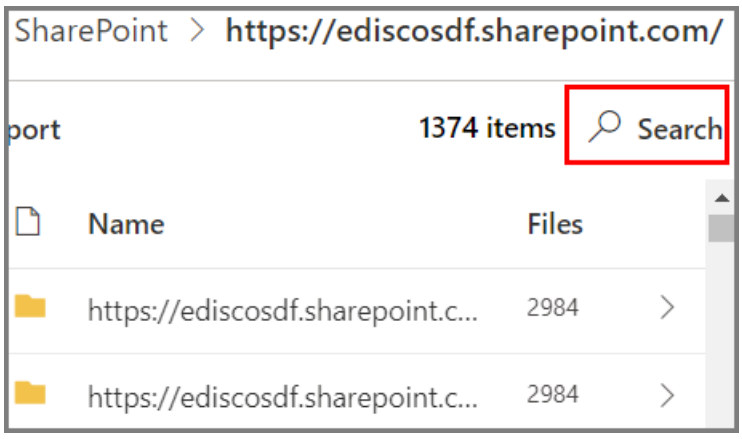
Export

The **export** control will create a .csv file that contains a listing of whatever is showing in the **All locations** pane.



Search

When you drill down into a location, such as an Exchange folder, or a SharePoint or OneDrive site, the **search** tool appears.



The scope of the search tool is what is displaying in the **All locations** pane and what you can search on varies depending on the selected location.

When **Exchange** is the selected location, you can search on the full email address of the mailbox, for example `user@domainname.com`.

When either **SharePoint** or **OneDrive** are selected location, the search tool will appear when you drill down to site names, folders and files.

> **NOTE**
>
> **OneDrive** We have listened to your valuable feedback on OneDrive integration during our preview program. Based on that feedback, the OneDrive functionality will remain in preview till all fixes are in place. Depending on your tenant, some customers may not see OneDrive as a location. We appreciate your continued support on this.

You can search on:

VALUE	EXAMPLE
full site name	`https://contoso.onmicrosoft.com/sites/sitename`
root folder name - gets all subfolders	`/sites`

VALUE	EXAMPLE
file name	`RES_Resume_1234.txt`
text at the beginning of file name	`RES`
text after an underscore character (_) in file name	`Resume` or `1234`
file extension	`txt`

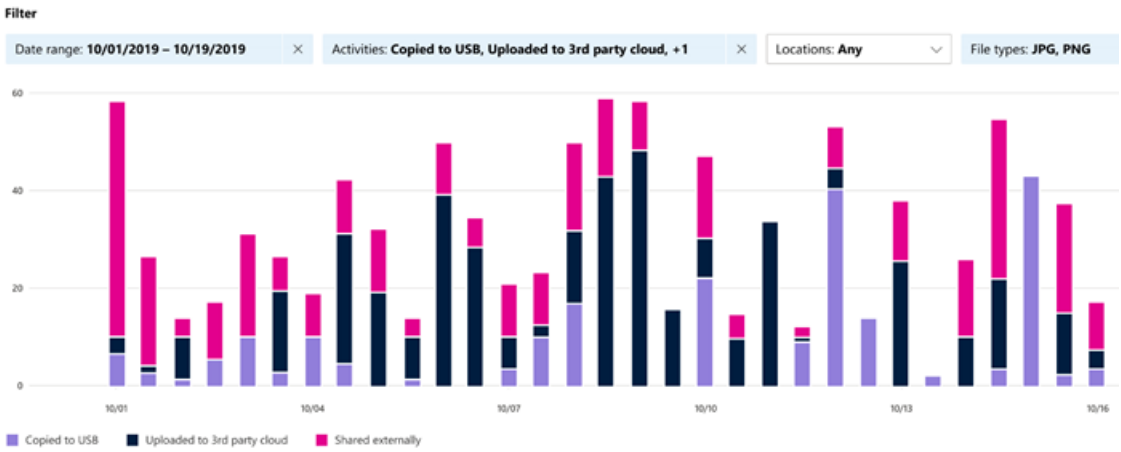
Get started with activity explorer

2/18/2021 • 2 minutes to read • Edit Online

The data classification overview and content explorer tabs give you visibility into what content has been discovered and labeled, and where that content is. Activity explorer rounds out this suite of functionality by allowing you to monitor what's being done with your labeled content. Activity explorer provides a historical view.



There are over 30 different filters available for use, some are:

- date range
- activity type
- location
- user
- sensitivity label
- retention label
- file path
- DLP policy

Prerequisites

Every account that accesses and uses data classification must have a license assigned to it from one of these subscriptions:

- Microsoft 365 (E5)
- Office 365 (E5)
- Advanced Compliance (E5) add-on
- Advanced Threat Intelligence (E5) add-on
- Microsoft 365 E5/A5 Info Protection & Governance
- Microsoft 365 E5/A5 Compliance

Permissions

In order to get access to the activity explorer tab, an account must be assigned membership in any one of these roles or role groups.

Microsoft 365 role groups

- Global administrator

- Compliance administrator
- Security administrator
- Compliance data administrator

Activity type

Microsoft 365 monitors and reports on types of activities across SharePoint Online, and OneDrive like:

- label applied
- label changed (upgraded, downgraded, or removed)
- auto-labeling simulation

The value of understanding what actions are being taken with your sensitive labeled content is that you can see if the controls that you have already put into place, such as data loss prevention policies are effective or not. If not, or if you discover something unexpected, such as a large number of items that are labeled `highly confidential` and are downgraded `general`, you can manage your various policies and take new actions to restrict the undesired behavior.

> **NOTE**
> Activity explorer doesn't currently monitor retention activities for Exchange Online.

Data classification release notes

2/18/2021 • 2 minutes to read • Edit Online

Exchange mailbox count

You will notice a small tool tip appear when you drill into Exchange mailboxes. This is to call out the fact that the aggregate count displayed for sensitive information type, sensitivity label and retention label may not exactly match the number of items that you will find inside the mailbox. This is because the drill-down into the folder fetches the live view of content, which is classified, while the aggregated count is calculated.

Rendering of encrypted documents

SharePoint, Exchange, and OneDrive files that are encrypted don't render in the content explorer. This is a sensitive issue that requires a balance between the need to see file contents in content explorer and the need to keep the contents encrypted. With the permissions granted by **Content Explorer List Viewer**, and **Content Explorer Content Viewer** role groups, you will see a list view of the files, the file metadata, and a link you can use to access the content via the web client.

Supported characters in retention label names in SharePoint search

SharePoint search doesn't support retention label names with `-`, or `_` in them. For example, `Label-MIP` and `Label_MIP` aren't supported. SharePoint search does support those characters in sensitivity label names and sensitive information type names.

OneDrive remains in preview

Thanks for your valuable feedback on OneDrive integration during our preview program. As we work through the specifics, you may run into inconsistent data / flows. We'll continue to showcase OneDrive in preview until all fixes are in place. We appreciate your continued support.

Learn about sensitivity labels

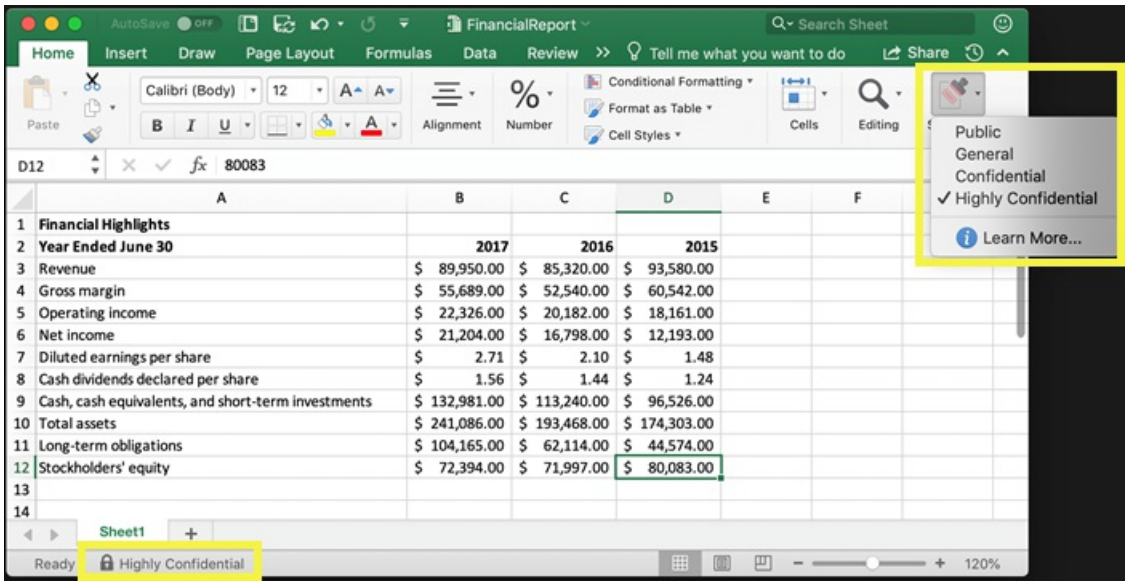
2/18/2021 • 17 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

To get their work done, people in your organization collaborate with others both inside and outside the organization. This means that content no longer stays behind a firewall—it can roam everywhere, across devices, apps, and services. And when it roams, you want it to do so in a secure, protected way that meets your organization's business and compliance policies.

Sensitivity labels from the Microsoft Information Protection solution let you classify and protect your organization's data, while making sure that user productivity and their ability to collaborate isn't hindered.

Example showing available sensitivity labels in Excel, from the **Home** tab on the Ribbon. In this example, the applied label displays on the status bar:



To apply sensitivity labels, users must be signed in with their Microsoft 365 work or school account.

> **NOTE**
>
> Sensitivity labels are newly supported For US Government tenants (GCC and GCC-H). For more information, see the release notes for Microsoft 365 Apps for enterprise, Version 2101: January 26.
>
> For the Azure Information Protection unified labeling client and scanner, see Azure Information Protection Premium Government Service Description.

You can use sensitivity labels to:

- **Provide protection settings that include encryption and content markings.** For example, apply a "Confidential" label to a document or email, and that label encrypts the content and applies a "Confidential" watermark. Content markings include headers and footers as well as watermarks, and encryption can also restrict what actions authorized people can take on the content.
- **Protect content in Office apps across different platforms and devices.** Supported by Word, Excel, PowerPoint, and Outlook on the Office desktop apps and Office on the web. Supported on Windows, macOS, iOS, and Android.

- **Protect content in third-party apps and services** by using Microsoft Cloud App Security. With Cloud App Security, you can detect, classify, label, and protect content in third-party apps and services, such as SalesForce, Box, or DropBox, even if the third-party app or service does not read or support sensitivity labels.
- **Protect containers** that include Teams, Microsoft 365 Groups, and SharePoint sites. For example, set privacy settings, external user access and external sharing, and access from unmanaged devices.
- **Extend sensitivity labels to Power BI**: When you turn on this capability, you can apply and view labels in Power BI, and protect data when it's saved outside the service.
- **Extend sensitivity labels to assets in Azure Purview**: When you turn on this capability, currently in preview, you can apply your sensitivity labels to assets such as SQL columns, files in Azure Blob Storage, and more.
- **Extend sensitivity labels to third-party apps and services.** Using the Microsoft Information Protection SDK, third-party apps can read sensitivity labels and apply protection settings.
- **Classify content without using any protection settings.** You can also simply assign a label as a result of classifying the content. This provides users with a visual mapping of classification to your organization's label names, and can use the labels to generate usage reports and see activity data for your sensitive content. Based on this information, you can always choose to apply protection settings later.

In all these cases, sensitivity labels in Microsoft 365 can help you take the right actions on the right content. With sensitivity labels, you can classify data across your organization, and enforce protection settings based on that classification.

For more information about these and other scenarios that are supported by sensitivity labels, see Common scenarios for sensitivity labels. New features are being developed all the time that support sensitivity labels, so you might also find it useful to reference the Microsoft 365 roadmap.

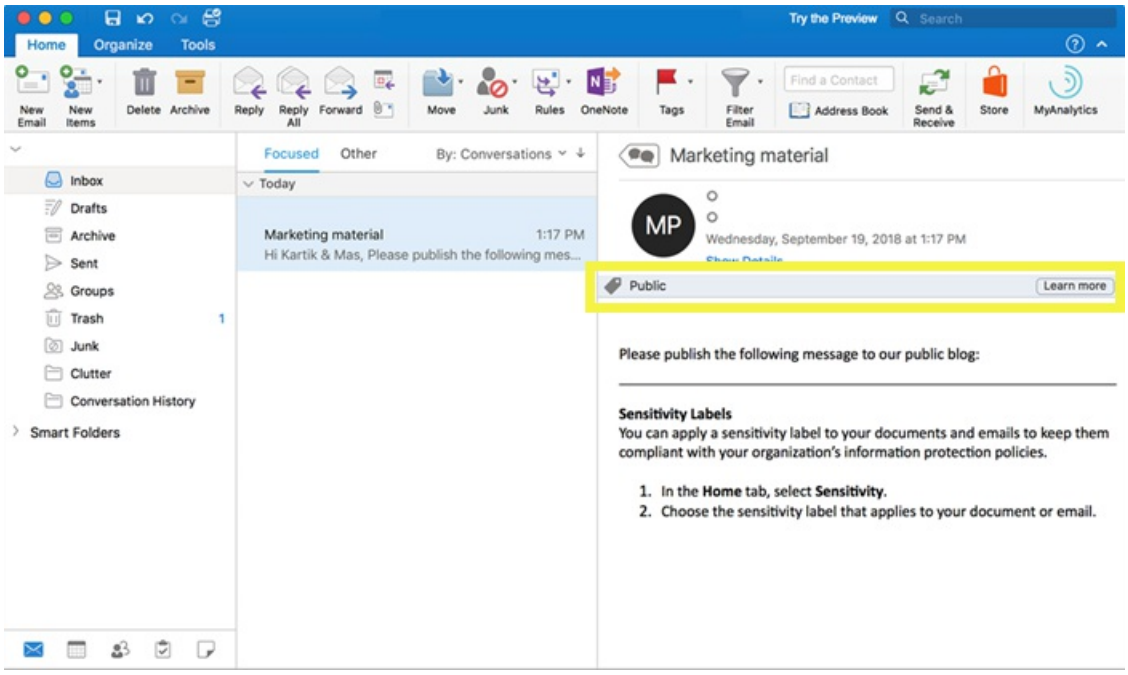
What a sensitivity label is

When you assign a sensitivity label to content, it's like a stamp that's applied and is:

- **Customizable.** Specific to your organization and business needs, you can create categories for different levels of sensitive content in your organization. For example, Personal, Public, General, Confidential, and Highly Confidential.
- **Clear text.** Because a label is stored in clear text in the metadata for files and emails, third-party apps and services can read it and then apply their own protective actions, if required.
- **Persistent.** Because the label is stored in metadata for files and emails, the label roams with the content, no matter where it's saved or stored. The unique label identification becomes the basis for applying and enforcing the policies that you configure.

When viewed by users, a sensitivity label appears like a tag on apps that they use and can be easily integrated into their existing workflows.

Each item that supports sensitivity labels can have a single sensitivity label applied to it. Documents and emails can have both a sensitivity label and a retention label applied to them.



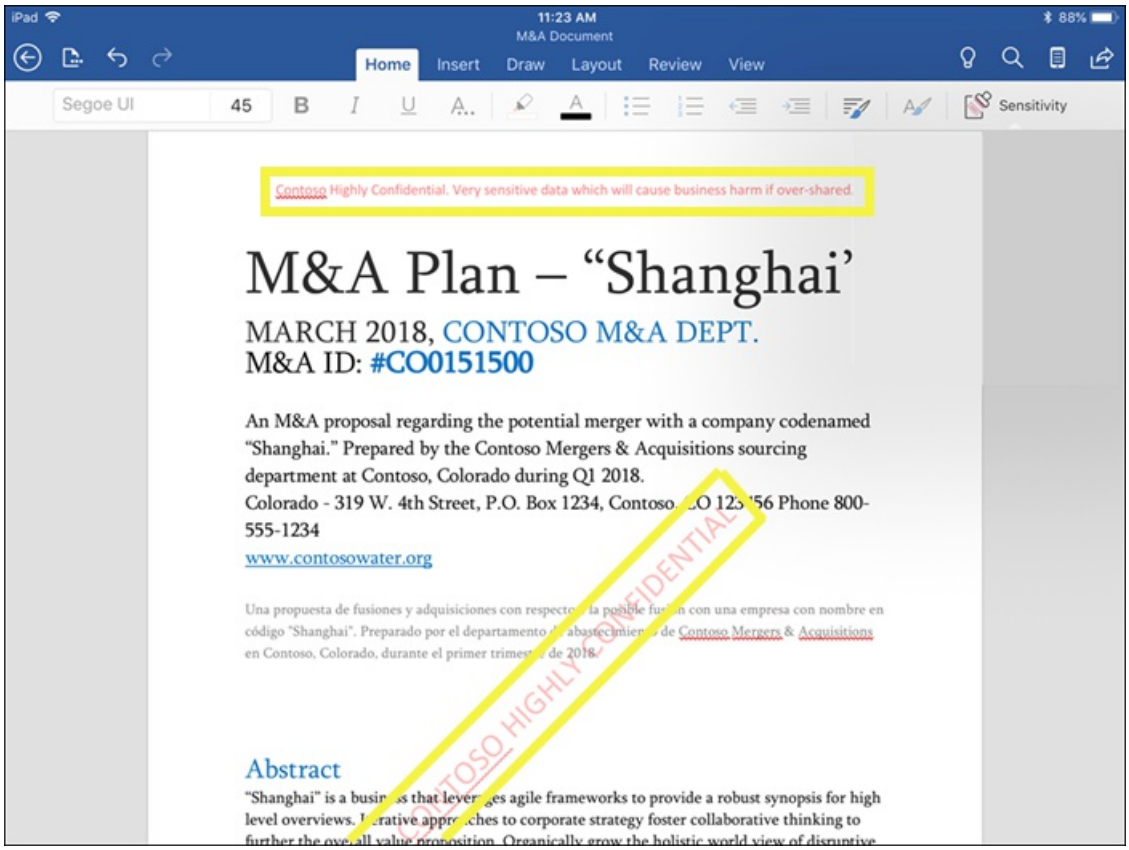
What sensitivity labels can do

After a sensitivity label is applied to an email or document, any configured protection settings for that label are enforced on the content. You can configure a sensitivity label to:

- **Encrypt** emails and documents to prevent unauthorized people from accessing this data. You can additionally choose which users or group have permissions to perform which actions and for how long. For example, you can choose to allow all users in your organization to modify a document while a specific group in another organization can only view it. Alternatively, instead of administrator-defined permissions, you can allow your users to assign permissions to the content when they apply the label.

  For more information about the **Encryption** settings when you create or edit a sensitivity label, see Restrict access to content by using encryption in sensitivity labels.

- **Mark the content** when you use Office apps, by adding watermarks, headers, or footers to email or documents that have the label applied. Watermarks can be applied to documents but not email. Example header and watermark:



Need to check when content markings are applied? See When Office apps apply content marking and encryption.

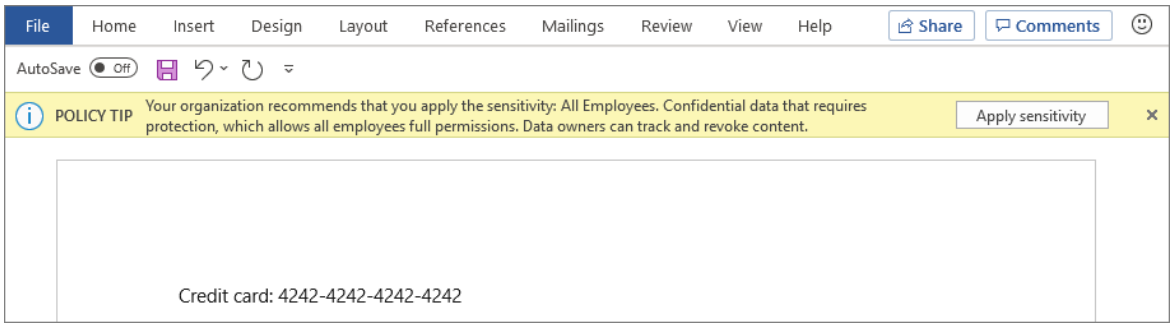
Some, but not all apps support dynamic markings by using variables. For example, insert the label name or document name into the header, footer, or watermark. For more information, see Dynamic markings with variables.

String lengths: Watermarks are limited to 255 characters. Headers and footers are limited to 1024 characters, except in Excel. Excel has a total limit of 255 characters for headers and footers but this limit includes characters that aren't visible, such as formatting codes. If that limit is reached, the string you enter is not displayed in Excel.

- **Protect content in containers such as sites and groups** when you enable the capability to use sensitivity labels with Microsoft Teams, Microsoft 365 groups, and SharePoint sites.

  You can't configure protection settings for groups and sites until you enable this capability. This label configuration doesn't result in documents or emails being automatically labeled but instead, the label settings protect content by controlling access to the container where content can be stored. These settings include privacy settings, external user access and external sharing, and access from unmanaged devices.

- **Apply the label automatically to files and emails, or recommend a label.** Choose how to identify sensitive information that you want labeled, and the label can be applied automatically, or you can prompt users to apply the label that you recommend. If you recommend a label, the prompt displays whatever text you choose. For example:



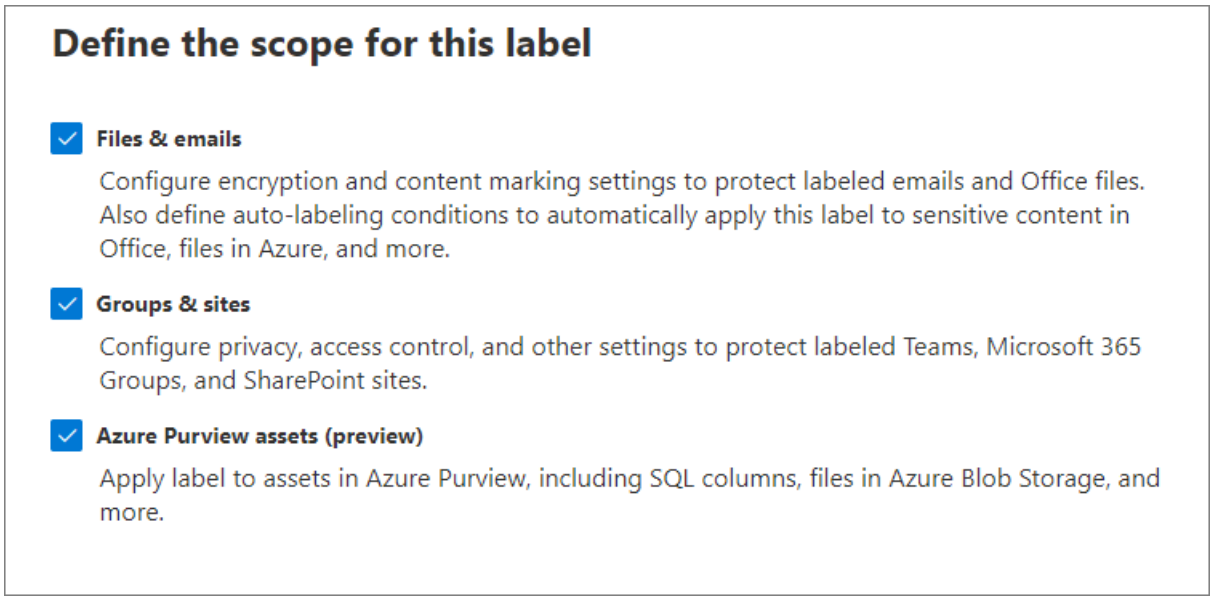
For more information about the **Auto-labeling for files and emails** settings when you create or edit a sensitivity label, see Apply a sensitivity label to content automatically for Office apps, and Automatically label your data in Azure Purview.

Label scopes

When you create a sensitivity label, you're asked to configure the label's scope which determines two things:

- Which label settings you can configure for that label
- Where the label will be visible to users

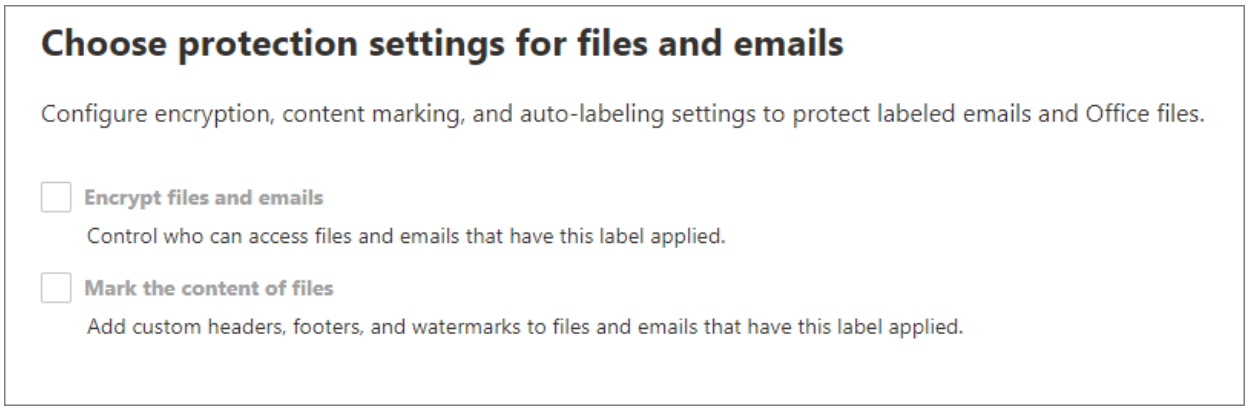
This scope configuration lets you have sensitivity labels that are just for documents and emails and can't be selected for containers. And similarly, sensitivity labels that are just for containers and can't be selected for documents and emails. New, and currently in preview, you can also select the scope for Azure Purview assets:



By default, the **Files & emails** scope is always selected. The other scopes are selected by default when the features are enabled for your tenant:

- **Groups & sites**: Enable sensitivity labels for containers and synchronize labels
- **Azure Purview assets (preview)**: Automatically label your content in Azure Purview

If you change the defaults so not all scopes are selected, you see the first page of the configuration settings for scopes you haven't selected, but you can't configure the settings. For example, if the scope for files and emails is not selected, you can't select the options on the next page:



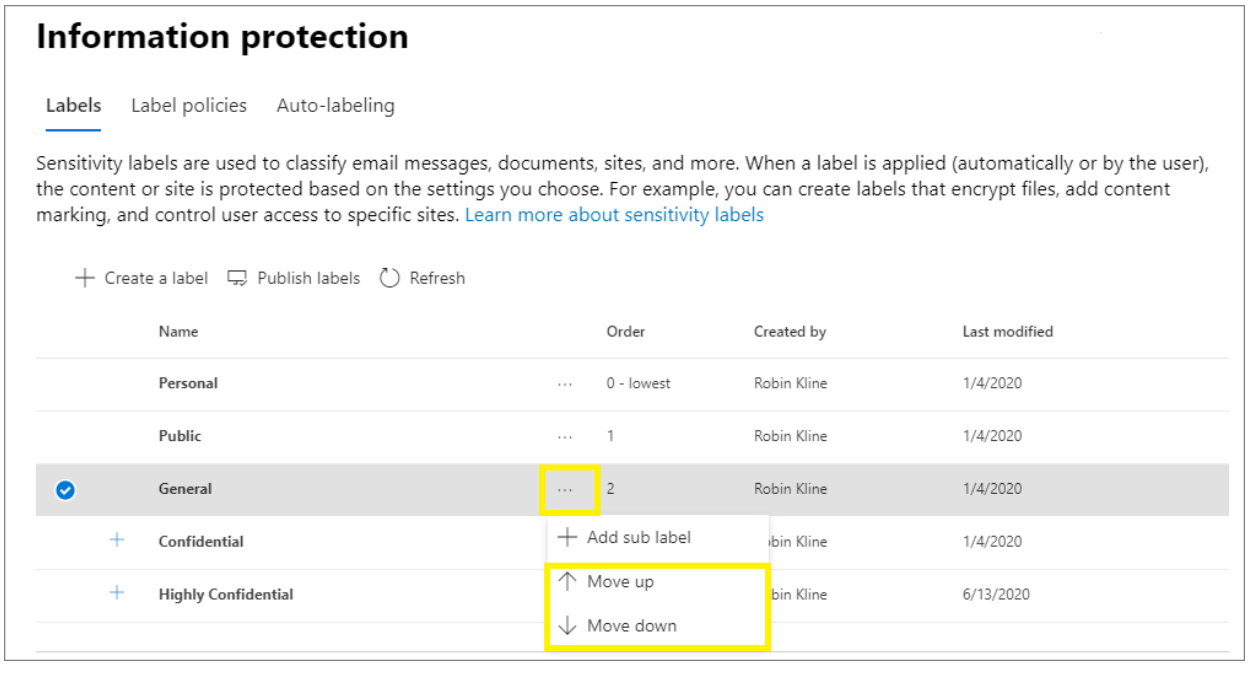
For these pages that have unavailable options, select **Next** to continue. Or, select **Back** to change the label's scope.

Label priority (order matters)

When you create your sensitivity labels in your admin center, they appear in a list on the **Sensitivity** tab on the **Labels** page. In this list, the order of the labels is important because it reflects their priority. You want your most restrictive sensitivity label, such as Highly Confidential, to appear at the **bottom** of the list, and your least restrictive sensitivity label, such as Public, to appear at the **top**.

You can apply just one sensitivity label to an item such as a document, email, or container. If you set an option that requires your users to provide a justification for changing a label to a lower classification, the order of this list identifies the lower classifications. However, this option does not apply to sublabels.

The ordering of sublabels is used with automatic labeling, though. When you configure labels to be applied automatically or as a recommendation, multiple matches can result for more than one label. To determine the label to apply or recommend, the label ordering is used: The last sensitive label is selected, and then if applicable, the last sublabel.



Sublabels (grouping labels)

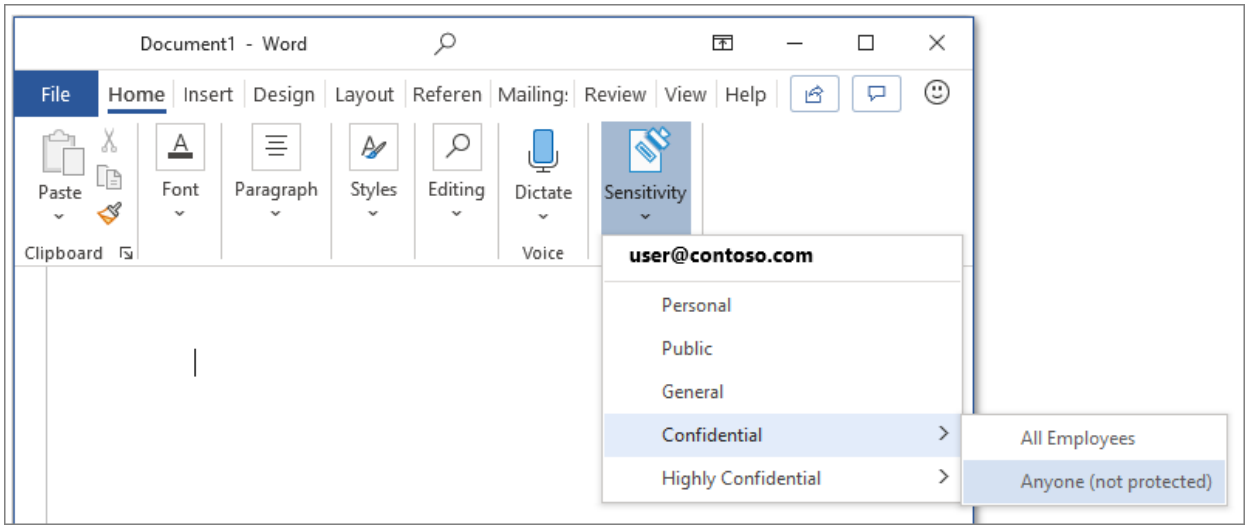
With sublabels, you can group one or more labels below a parent label that a user sees in an Office app. For example, under Confidential, your organization might use several different labels for specific types of that classification. In this example, the parent label Confidential is simply a text label with no protection settings, and because it has sublabels, it can't be applied to content. Instead, users must choose Confidential to view the sublabels, and then they can choose a sublabel to apply to content.

Sublabels are simply a way to present labels to users in logical groups. Sublabels don't inherit any settings from

their parent label. When you publish a sublabel for a user, that user can then apply that sublabel to content but can't apply just the parent label.

Don't choose a parent label as the default label, or configure a parent label to be automatically applied (or recommended). If you do, the parent label won't be applied to content.

Example of how sublabels display for users:



Editing or deleting a sensitivity label

If you delete a sensitivity label from your admin center, the label is not automatically removed from content, and any protection settings continue to be enforced on content that had that label applied.

If you edit a sensitivity label, the version of the label that was applied to content is what's enforced on that content.

What label policies can do

After you create your sensitivity labels, you need to publish them, to make them available to people and services in your organization. The sensitivity labels can then be applied to Office documents and emails, and other items that support sensitivity labels.

Unlike retention labels, which are published to locations such as all Exchange mailboxes, sensitivity labels are published to users or groups. Apps that support sensitivity labels can then display them to those users and groups as applied labels, or as labels that they can apply.

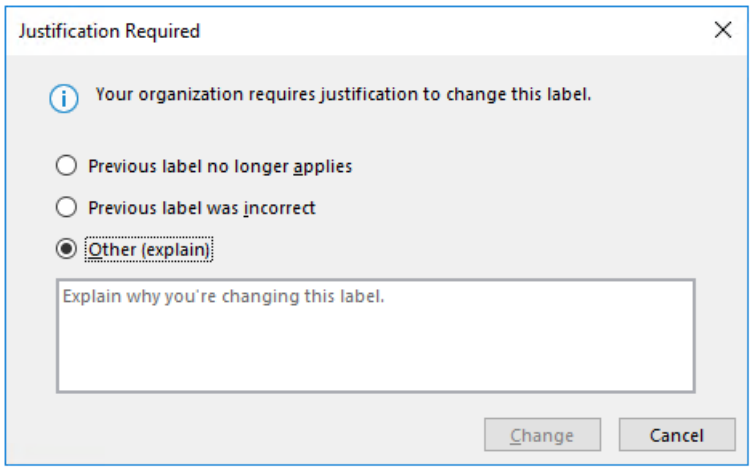
When you configure a label policy, you can:

- **Choose which users and groups see the labels.** Labels can be published to any specific user or email-enabled security group, distribution group, or Microsoft 365 group (which can have dynamic membership) in Azure AD.
- **Apply a default label** to all new documents and email created by the users and groups included in the label policy, and the same or different default label to containers (if you've enabled sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites). Users can always change the default label if it's not the right label for their document or email.

  Consider using a default label to set a base level of protection settings that you want applied to all your content. However, without user training and other controls, this setting can also result in inaccurate labeling. It's usually not a good idea to select a label that applies encryption as a default label to documents. For example, many organizations need to send and share documents with external users who might not have apps that support the encryption or they might not use an account that can be authorized. For more information about this scenario, see Sharing encrypted documents with external

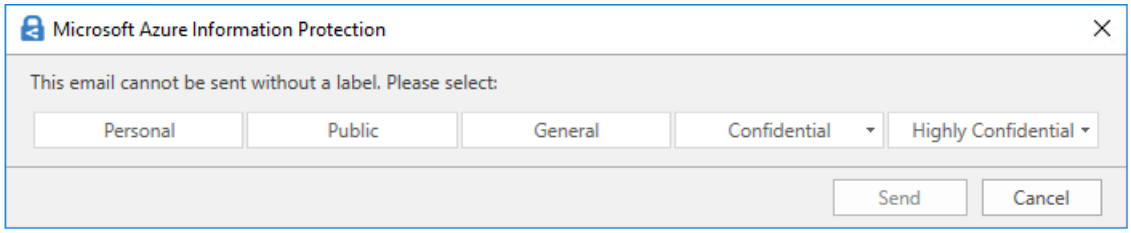
users.

- **Require a justification for changing a label.** If a user tries to remove a label or replace it with a label that has a lower-order number, you can require the user provides a justification to perform this action. For example, a user opens a document labeled Confidential (order number 3) and replaces that label with one named Public (order number 1). Currently, the justification reason is used only by the Azure Information Protection unified labeling client, which sends this information to Azure Information Protection analytics.



- **Require users to apply a label** with one option for email and documents, and another for containers. Also known as mandatory labeling, these options ensure a label must be applied before users can save documents and send emails, and create new groups or sites.

  For documents and emails, a label can be assigned manually by the user, automatically as a result of a condition that you configure, or be assigned by default (the default label option previously described). An example prompt shown in Outlook when a user is required to assign a label:

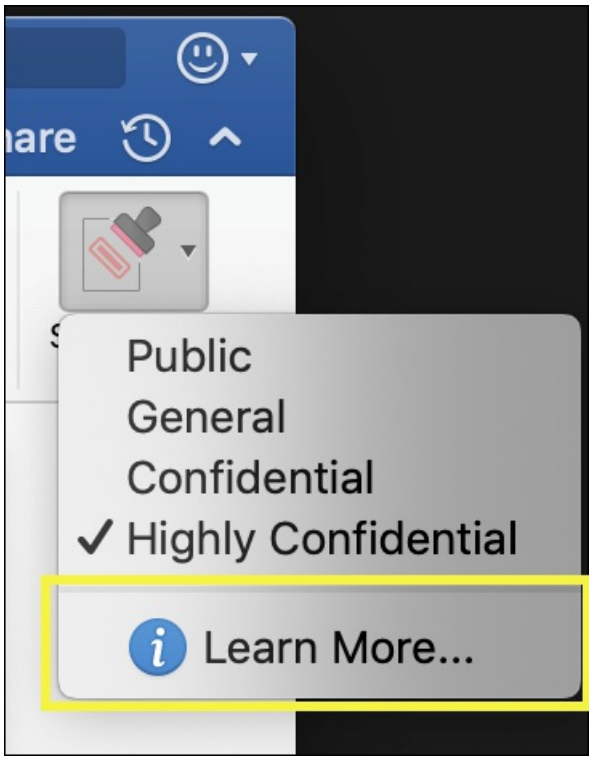


> **NOTE**
> Mandatory labeling for documents and emails isn't available for all apps or all platforms. For more information, see Require users to apply a label to their email and documents.

  For containers, a label must be assigned at the time the group or site is created.

  Consider using this option to help increase your labeling coverage. However, without user training, these settings can result in inaccurate labeling. In addition, unless you also set a corresponding default label, mandatory labeling can frustrate your users with the frequent prompts.

- **Provide help link to a custom help page.** If your users aren't sure what your sensitivity labels mean or how they should be used, you can provide a Learn More URL that appears at the bottom of the **Sensitivity label** menu in the Office apps:



After you create a label policy that assigns new sensitivity labels to users and groups, users start to see those labels in their Office apps. Allow up to 24 hours for the latest changes to replicate throughout your organization.

There is no limit to the number of sensitivity labels that you can create and publish, with one exception: If the label applies encryption, there is a maximum of 500 labels that you can create. However, as a best practice to lower admin overheads and reduce complexity for your users, try to keep the number of labels to a minimum. Real-world deployments have proved effectiveness to be noticeably reduced when users have more than five main labels or more than five sublabels per main label.

Label policy priority (order matters)

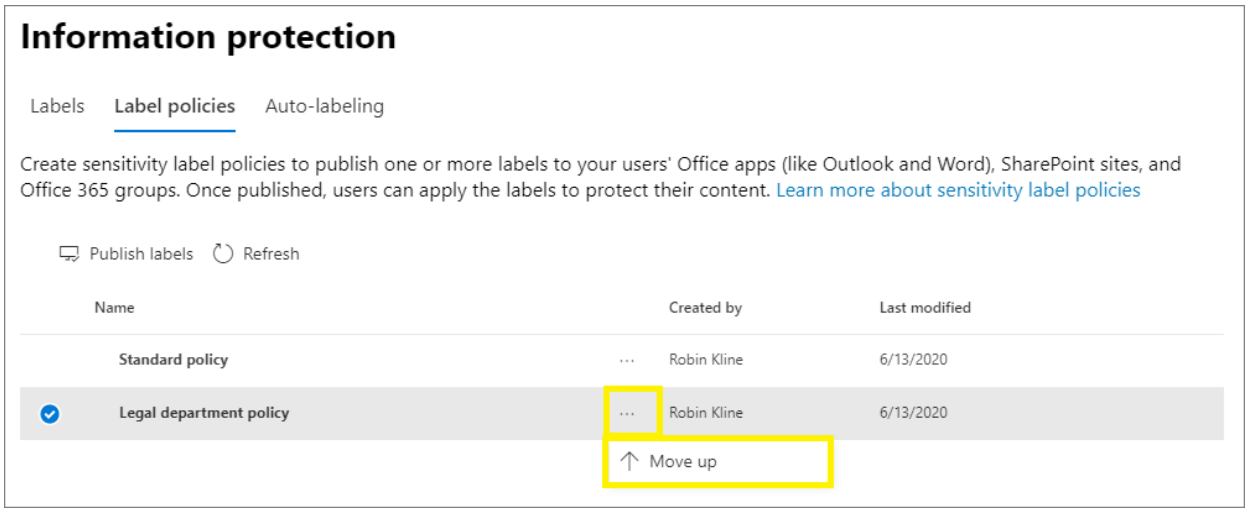
You make your sensitivity labels available to users by publishing them in a sensitivity label policy that appears in a list on the **Sensitivity policies** tab on the **Label policies** page. Just like sensitivity labels (see Label priority (order matters)), the order of the sensitivity label policies is important because it reflects their priority. The label policy with lowest priority is shown at the **top**, and the label policy with the highest priority is shown at the **bottom**.

A label policy consists of:

- A set of labels.
- The users and groups that will be assigned the policy with labels.
- The scope of the policy and policy settings for that scope (such as default label for files and emails).

You can include a user in multiple label policies, and the user will see all the sensitivity labels from those policies. However, a user gets the policy settings from only the label policy with the highest priority.

If you're not seeing the label or label policy setting that you expect for a user or group, check the order of the sensitivity label policies. To reorder the label policies, select a sensitivity label policy > choose the ellipsis on the right > **Move down** or **Move up**.



If you use retention labels in addition to sensitivity labels, it's important to remember that priority matters for sensitivity label policies, but not for retention labels.

Sensitivity labels and Azure Information Protection

If you have deployed labels with Azure Information Protection, use the following sections for guidance before you start to use sensitivity labels.

Azure Information Protection labels

> **NOTE**
> Label management for Azure Information Protection labels in the Azure portal is being deprecated **March 31, 2021**. Learn more from the official deprecation notice.

If you are using Azure Information Protection labels because your tenant isn't yet on the unified labeling platform, we recommend that you avoid creating sensitivity labels until you activate unified labeling. In this scenario, the labels you see in the Azure portal are Azure Information Protection labels rather than sensitivity labels. These labels can be used by the Azure Information Protection client (classic) on Windows computers, but can't be used by devices running macOS, iOS, or Android. To resolve this, migrate these labels to sensitivity labels.

The metadata applied by both sets of labels are compatible, so you don't need to relabel documents and emails when the migration is complete.

Azure Information Protection clients

When you use sensitivity labels in Microsoft 365 Apps for enterprise apps on Windows computers, you have a choice of using an Azure Information Protection client, or use labeling that's built into Office.

By default, built-in labeling is turned off in these apps when the Azure Information Protection client is installed. For more information, including how to change this default behavior, see Office built-in labeling client and the Azure Information Protection client.

Even when you use built-in labeling in Office apps, you can also use the Azure Information Protection unified labeling client with sensitivity labels for the following:

- A scanner to discover sensitive information that's stored on-premises, and then optionally, label that content
- Right-click options in File Explorer for users to apply labels to all file types
- A viewer to display encrypted files for text, images, or PDF documents

- A PowerShell module to discover sensitive information in files on premises, and apply or remove labels and encryption from these files.

If you are new to Azure Information Protection, or if you are an existing Azure Information Protection customer that has just migrated your labels, see Choose which labeling client to use for Windows computers from the Azure Information Protection documentation.

Sensitivity labels and Microsoft Cloud App Security

By using Cloud App Security (CAS), you can discover, classify, label, and protect content in third-party services and apps, such as SalesForce, Box, or Dropbox.

Cloud App Security works with both Azure Information Protection labels and sensitivity labels:

- If the labeling admin centers have one or more sensitivity labels published to at least one user: Sensitivity labels are used.
- If the labeling admin centers don't have sensitivity labels published: Azure Information Protection labels are used.

For instructions to use Cloud App Security with these labels, see Azure Information Protection integration.

Sensitivity labels and the Microsoft Information Protection SDK

Because a sensitivity label is stored as clear text in the metadata of a document, third-party apps and services can read from and write to this labeling metadata to supplement your labeling deployment. Additionally, software developers can use the Microsoft Information Protection SDK to fully support labeling and encryption capabilities across multiple platforms. To learn more, see the General Availability announcement on the Tech Community blog.

You can also learn about partner solutions that are integrated with Microsoft Information Protection.

Deployment guidance

For deployment planning and guidance that includes licensing information, permissions, deployment strategy, a list of supported scenarios, and end-user documentation, see Get started with sensitivity labels.

Get started with sensitivity labels

2/18/2021 • 6 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

For information about what sensitivity labels are and how they can help you protect your organization's data, see Learn about sensitivity labels.

If you have Azure Information Protection, determine whether you need to migrate labels to the unified labeling platform, and which labeling client to use:

- How can I determine if my tenant is on the unified labeling platform?
- Choose which labeling client to use for Windows computers

When you're ready to start protecting your organization's data by using sensitivity labels:

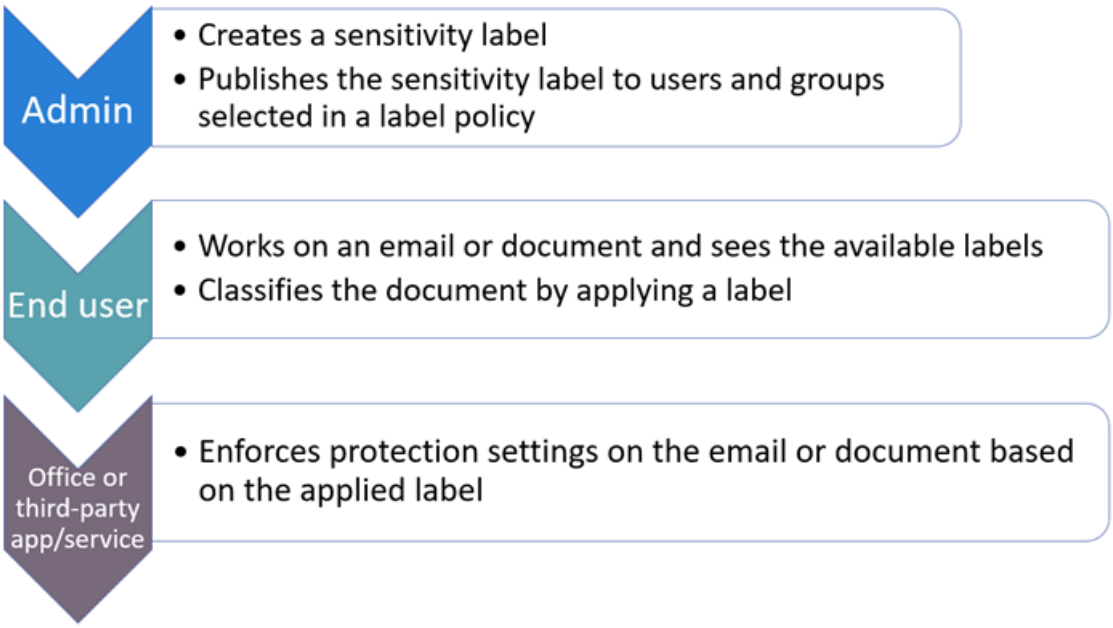
1. **Create the labels.** Create and name your sensitivity labels according to your organization's classification taxonomy for different sensitivity levels of content. Use common names or terms that make sense to your users. If you don't already have an established taxonomy, consider starting with label names such as Personal, Public, General, Confidential, and Highly Confidential. You can then use sublabels to group similar labels by category. When you create a label, use the tooltip text to help users select the appropriate label.

   For more extensive guidance for defining a classification taxonomy, download the white paper, "Data Classification & Sensitivity Label Taxonomy" from the Service Trust Portal.

2. **Define what each label can do.** Configure the protection settings you want associated with each label. For example, you might want lower sensitivity content (such as a "General" label) to have just a header or footer applied, while higher sensitivity content (such as a "Confidential" label) should have a watermark and encryption.

3. **Publish the labels.** After your sensitivity labels are configured, publish them by using a label policy. Decide which users and groups should have the labels and what policy settings to use. A single label is reusable—you define it once, and then you can include it in several label policies assigned to different users. So for example, you could pilot your sensitivity labels by assigning a label policy to just a few users. Then when you're ready to roll out the labels across your organization, you can create a new label policy for your labels and this time, specify all users.

The basic flow for deploying and applying sensitivity labels:



Subscription and licensing requirements for sensitivity labels

A number of different subscriptions support sensitivity labels and the licensing requirements for users depend on the features you use.

To see the options for licensing your users to benefit from Microsoft 365 compliance features, see the Microsoft 365 licensing guidance for security & compliance. For sensitivity labels, see the Information Protection section and related PDF or Excel download.

Permissions required to create and manage sensitivity labels

Members of your compliance team who will create sensitivity labels need permissions to the Microsoft 365 compliance center, Microsoft 365 security center, or the Security & Compliance Center.

By default, global administrators for your tenant have access to these admin centers and can give compliance officers and other people access, without giving them all of the permissions of a tenant admin. For this delegated limited admin access, add users to the **Compliance Data Administrator**, **Compliance Administrator**, or **Security Administrator** role group.

Alternatively to using the default roles, you can create a new role group and add either **Sensitivity Label Administrator** or **Organization Configuration** roles to this group. For a read-only role, use **Sensitivity Label Reader**.

For instructions to add users to the default roles or create your own role groups, see Give users access to the Office 365 Security & Compliance Center.

These permissions are required only to create and configure sensitivity labels and their label policies. They are not required to apply the labels in apps or services. If additional permissions are needed for specific configurations that relate to sensitivity labels, those permissions will be listed in their respective documentation instructions.

Deployment strategy for sensitivity labels

A successful strategy to deploy sensitivity labels for an organization is to create a working virtual team that identifies and manages the business and technical requirements, proof of concept testing, internal checkpoints and approvals, and final deployment for the production environment.

Using the table in the next section, we recommend identifying your top one or two scenarios that map to your

most impactful business requirements. After these scenarios are deployed, return to the list to identify the next one or two priorities for deployment.

You'll find additional general deployment guidance in the downloadable Data Loss Prevention and Microsoft Information Protection Deployment Acceleration Guide. For more information, see the blog post, Microsoft 365 Information Protection and Compliance Deployment Acceleration Guides.

Common scenarios for sensitivity labels

All scenarios require you to Create and configure sensitivity labels and their policies.

I WANT TO ...	DOCUMENTATION
Manage sensitivity labels for Office apps so that content is labeled as it's created—includes support for manual labeling on all platforms	Manage sensitivity labels in Office apps
Enable users to label and protect files from Windows computers using Office apps, File Explorer, and PowerShell	Azure Information Protection unified labeling client for Windows
Encrypt documents and emails with sensitivity labels and restrict who can access that content and how it can be used	Restrict access to content by using sensitivity labels to apply encryption
Enable sensitivity labels for Office on the web, with support for coauthoring, eDiscovery, data loss prevention, search—even when documents are encrypted	Enable sensitivity labels for Office files in SharePoint and OneDrive
Automatically apply sensitivity labels to documents and emails	Apply a sensitivity label to content automatically
Use sensitivity labels to protect content in Teams and SharePoint	Use sensitivity labels with Microsoft Teams, Microsoft 365 groups, and SharePoint sites
Prevent or warn users about sharing files or emails with a specific sensitivity label	Use sensitivity labels as conditions in DLP policies (preview)
Discover, label, and protect files stored in data stores that are on premises	Deploying the Azure Information Protection scanner to automatically classify and protect files
Discover, label, and protect files stored in data stores that are in the cloud	Discover, classify, label, and protect regulated and sensitive data stored in the cloud
Apply and view labels in Power BI, and protect data when it's saved outside the service	Sensitivity labels in Power BI
Monitor and understand how sensitivity labels are being used in my organization	Know your data - data classification overview Get started with data classification
Extend sensitivity labels to third-party apps and services	Microsoft Information Protection SDK
Extend sensitivity labels across content in Azure Blob Storage, Azure files, Azure Data Lake Storage Gen1, and Azure Data Lake Storage Gen12	Automatically label your content in Azure Purview

End-user documentation for sensitivity labels

The most effective end-user documentation will be customized guidance and instructions you provide for the label names and configurations you choose. For built-in labeling, you can use the label policy setting **Provide users with a link to a custom help page** to specify an internal link for this documentation. Users can then easily access it by selecting **Learn More** from the **Sensitivity** button on the Office ribbon for Word, PowerPoint, Excel, and Outlook.

To help you write your customized documentation, see the following blog post for a download package that you can use to train users and drive adoption: End User Training for Sensitivity Labels in M365 – How to Accelerate Your Adoption.

You can also use the following resources for basic instructions:

- Apply sensitivity labels to your files and email in Office
    - Known issues with sensitivity labels in Office
- Automatically apply or recommend sensitivity labels to your files and emails in Office
    - Known issues with automatically applying or recommending sensitivity labels
- Azure Information Protection unified labeling user guide

If your sensitivity labels apply encryption for PDF documents, these documents can be opened with Microsoft Edge on Windows or Mac. For more information, and alternative readers, see Which PDF readers are supported for protected PDFs?

Create and configure sensitivity labels and their policies

2/18/2021 • 11 minutes to read • Edit Online

> *Microsoft 365 licensing guidance for security & compliance*.

All Microsoft Information Protection solutions (sometimes abbreviated to MIP) are implemented by using sensitivity labels. To create and publish these labels, go to your labeling admin center, such as the Microsoft 365 compliance center. You can also use the Microsoft 365 security center, or the Security & Compliance Center.

First, create and configure the sensitivity labels that you want to make available for apps and other services. For example, the labels you want users to see and apply from Office apps.

Then, create one or more label policies that contain the labels and policy settings that you configure. It's the label policy that publishes the labels and settings for your chosen users and locations.

Before you begin

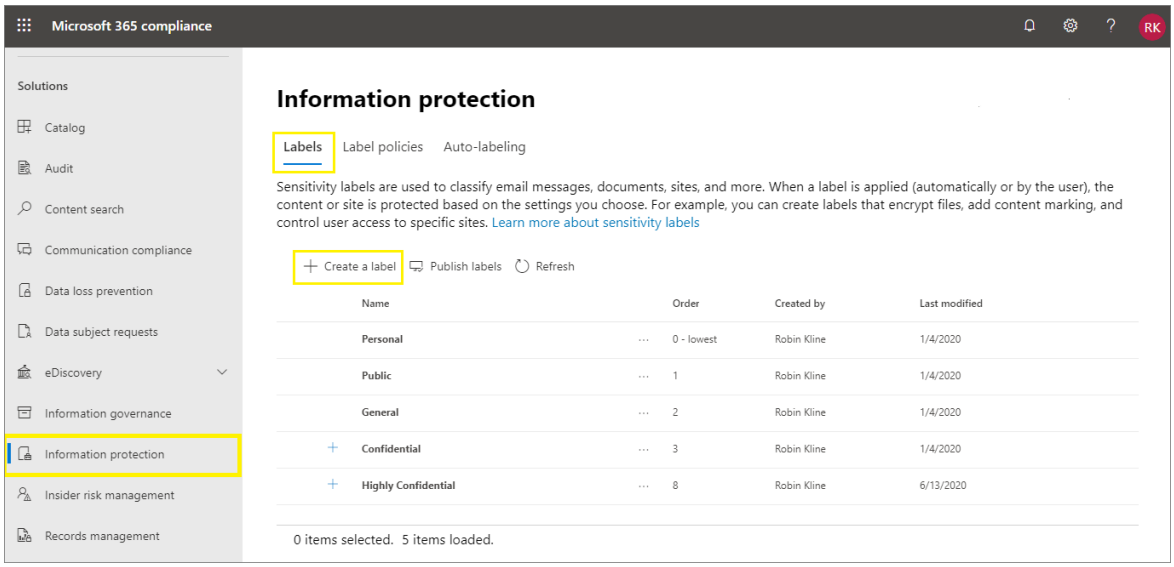
The global admin for your organization has full permissions to create and manage all aspects of sensitivity labels. If you aren't signing in as a global admin, see Permissions required to create and manage sensitivity labels.

Create and configure sensitivity labels

1. In your labeling admin center, navigate to sensitivity labels:
   - Microsoft 365 compliance center:
     - **Solutions** > **Information protection**

     If you don't immediately see this option, first select **Show all**.
   - Microsoft 365 security center:
     - **Classification** > **Sensitivity labels**
   - Security & Compliance Center:
     - **Classification** > **Sensitivity labels**
2. On the **Labels** page, select **+ Create a label** to start the New sensitivity label wizard.

   For example, from the Microsoft 365 compliance center:



> **NOTE**
>
> By default, tenants don't have any labels and you must create them. The labels in the example picture show default labels that were migrated from Azure Information Protection.

3. On the **Define the scope for this label** page, the options selected determine the label's scope for the settings that you can configure and where they will be visible when they are published:

   - If **Files & emails** is selected, you can configure settings in this wizard that apply to apps that support sensitivity labels, such as Office Word and Outlook. If this option isn't selected, the wizard displays the first page of these settings but you can't configure them and the labels won't be available for users to select in these apps.
   - If **Groups & sites** is selected, you can configure settings in this wizard that apply to Microsoft 365 groups, and sites for Teams and SharePoint. If this option isn't selected, the wizard displays the first page of these settings but you can't configure them and the labels won't be available for users to select for groups and site.

   For information about the **Azure Purview assets (preview)** scope, see Automatically label your content in Azure Purview.

4. Follow the prompts in the wizard for the label settings.

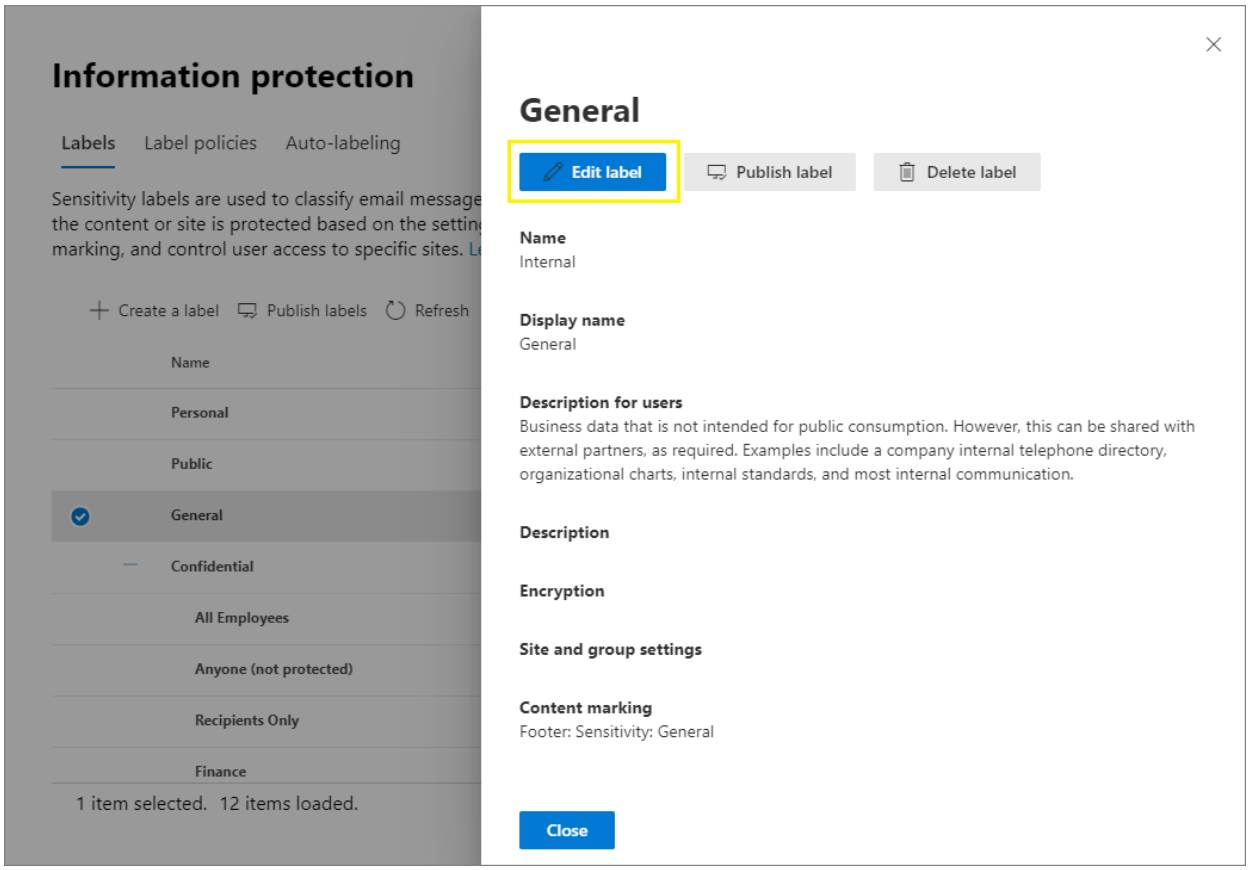
   For more information about the label settings, see What sensitivity labels can do from the overview

information and use the help in the wizard for individual settings.

5. Repeat these steps to create more labels. However, if you want to create a sublabel, first select the parent label and select ... for **More actions**, and then select **Add sub label**.

6. When you have created all the labels you need, review their order and if necessary, move them up or down. To change the order of a label, select ... for **More actions**, and then select **Move up** or **Move down**. For more information, see Label priority (order matters) from the overview information.

To edit an existing label, select it, and then select the **Edit label** button:



This button starts the **Edit sensitivity label** wizard, which lets you change all the label settings in step 4.

Don't delete a label unless you understand the impact for users. For more information, see the Removing and deleting labels section.

> **NOTE**
>
> If you edit a label that's already published by using a label policy, no extra steps are needed when you finish the wizard. For example, you don't need to add it to a new label policy for the changes to become available to the same users. However, allow up to 24 hours for the changes to replicate to all apps and services.

Until you publish your labels, they won't be available to select in apps or for services. To publish the labels, they must be added to a label policy.

> **IMPORTANT**
>
> On this **Labels** tab, do not select the **Publish labels** tab (or the **Publish label** button when you edit a label) unless you need to create a new label policy. You need multiple label policies only if users need different labels or different policy settings. Aim to have as few label policies as possible—it's not uncommon to have just one label policy for the organization.

Additional label settings with Security & Compliance Center PowerShell

Additional label settings are available with the Set-Label cmdlet from Security & Compliance Center PowerShell.

For example:

- Use the *LocaleSettings* parameter for multinational deployments so that users see the label name and tooltip in their local language. The following section has an example configuration that specifies the label name and tooltip text for French, Italian, and German.
- For the Azure Information Protection unified labeling client only, specify advanced settings that include setting a label color, and applying a custom property when a label is applied. For the full list, see Available advanced settings for labels from this client's admin guide.

Example configuration to configure a sensitivity label for different languages

The following example shows the PowerShell configuration for a label named "Public" with placeholder text for the tooltip. In this example, the label name and tooltip text are configured for French, Italian, and German.

As a result of this configuration, users who have Office apps that use those display languages see their label names and tooltips in the same language. Similarly, if you have the Azure Information Protection unified labeling client installed to label files from File Explorer, users who have those language versions of Windows see their label names and tooltips in their local language when they use the right-click actions for labeling.

For the languages that you need to support, use the Office language identifiers (also known as language tags), and specify your own translation for the label name and tooltip.

Before you run the commands in PowerShell, you must first connect to Security & Compliance Center PowerShell.

```
$Languages = @("fr-fr","it-it","de-de")
$DisplayNames=@("Publique","Publico","Oeffentlich")
$Tooltips = @("Texte Français","Testo italiano","Deutscher text")
$label = "Public"
$DisplayNameLocaleSettings = [PSCustomObject]@{LocaleKey='DisplayName';
Settings=@(
@{key=$Languages[0];Value=$DisplayNames[0];}
@{key=$Languages[1];Value=$DisplayNames[1];}
@{key=$Languages[2];Value=$DisplayNames[2];})}
$TooltipLocaleSettings = [PSCustomObject]@{LocaleKey='Tooltip';
Settings=@(
@{key=$Languages[0];Value=$Tooltips[0];}
@{key=$Languages[1];Value=$Tooltips[1];}
@{key=$Languages[2];Value=$Tooltips[2];})}
Set-Label -Identity $Label -LocaleSettings (ConvertTo-Json $DisplayNameLocaleSettings -Depth 3 -Compress),
(ConvertTo-Json $TooltipLocaleSettings -Depth 3 -Compress)
```

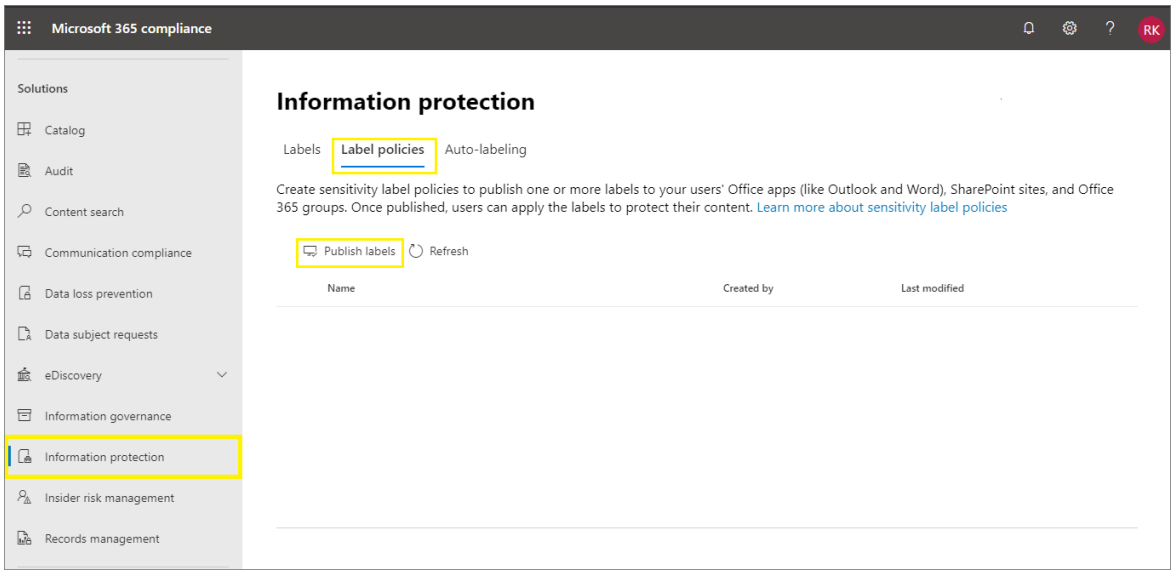
Publish sensitivity labels by creating a label policy

1. In your labeling admin center, navigate to sensitivity labels:
   - Microsoft 365 compliance center:
     - **Solutions** > **Information protection**

     If you don't immediately see this option, first select **Show all**.
   - Microsoft 365 security center:
     - **Classification** > **Sensitivity labels**
   - Security & Compliance Center:
     - **Classification** > **Sensitivity labels**

2. Select the **Label policies** tab, and then **Publish labels** to start the Create policy wizard:

   For example, from the Microsoft 365 compliance center:



> **NOTE**
>
> By default, tenants don't have any label policies and you must create them.

3. In the wizard, select **Choose sensitivity labels to publish**. Select the labels that you want to make available in apps and to services, and then select **Add**.

> **IMPORTANT**
>
> If you select a sublabel, make sure you also select its parent label.

4. Review the selected labels and to make any changes, select **Edit**. Otherwise, select **Next**.

5. Follow the prompts to configure the policy settings.

   The policy settings that you see match the scope of the labels that you selected. For example, if you selected labels that have just the **Files & emails** scope, you don't see the policy settings **Apply this label by default to groups and sites** and **Require users to apply a label to their groups and sites**.

   For more information about these settings, see What label policies can do from the overview information and use the help in the wizard for individual settings.

   For labels configured for **Azure Purview assets (preview)**: These labels don't have any associated policy settings.

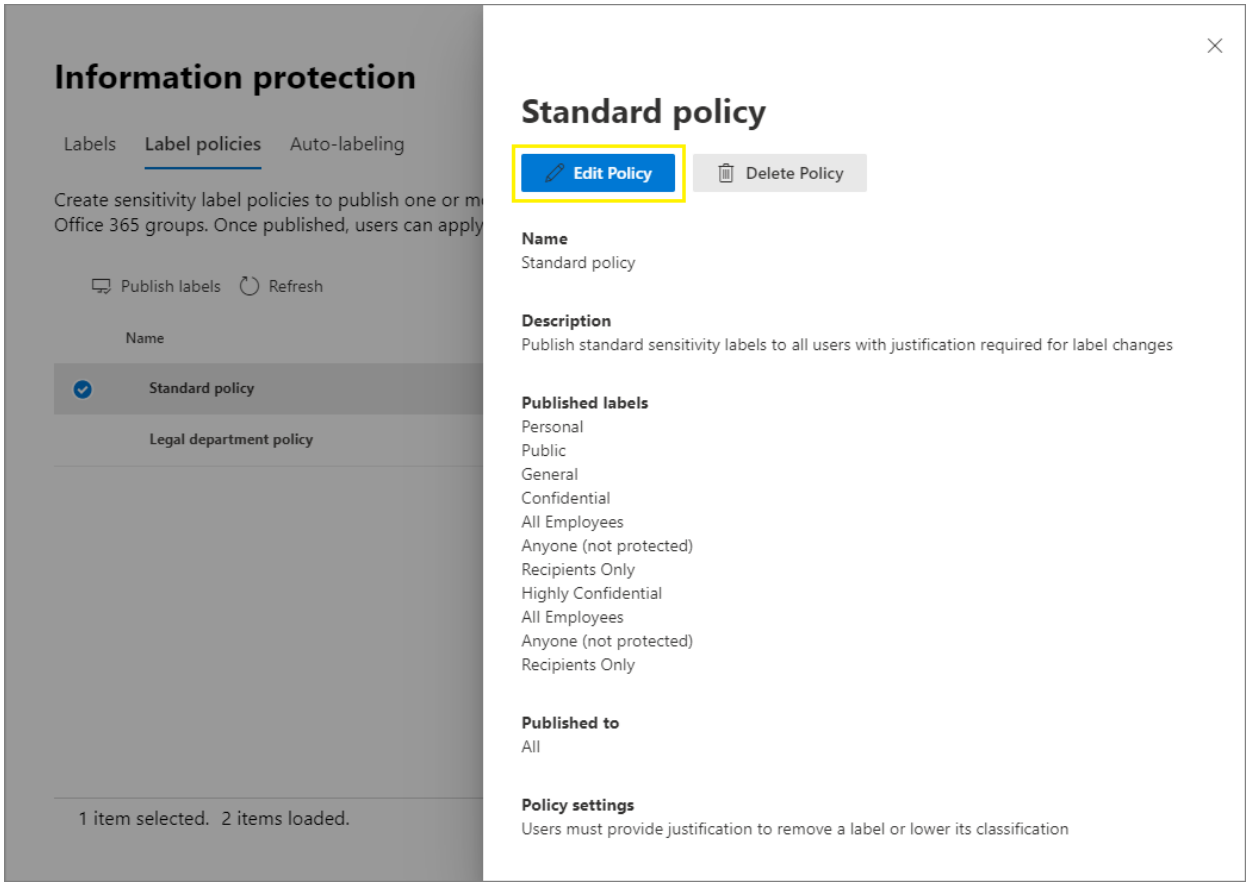
6. Repeat these steps if you need different policy settings for different users or scopes. For example, you want additional labels for a group of users, or a different default label for a subset of users. Or, if you have configured labels to have different scopes.

7. If you create more than one label policy that might result in a conflict for a user, review the policy order and if necessary, move them up or down. To change the order of a label policy, select **...** for **More actions**, and then select **Move up** or **Move down**. For more information, see Label policy priority (order matters) from the overview information.

Completing the wizard automatically publishes the label policy. To make changes to a published policy, simply

edit it. There is no specific publish or republish action for you to select.

To edit an existing label policy, select it, and then select the **Edit Policy** button:



This button starts the **Create policy** wizard, which lets you edit which labels are included and the label settings. When you complete the wizard, any changes are automatically replicated to the selected users and services.

When you use built-in labeling for Office apps on Windows, macOS, iOS, and Android, users see new labels within four hours, and within one hour for Office on the web. However, allow up to 24 hours for changes to replicate to all apps and services.

Additional label policy settings with Security & Compliance Center PowerShell

Additional label policy settings are available with the Set-LabelPolicy cmdlet from Security & Compliance Center PowerShell.

For the Azure Information Protection unified labeling client only, you can specify advanced settings that include setting a different default label for Outlook, and implement pop-up messages in Outlook that warn, justify, or block emails being sent. For the full list, see Available advanced settings for label policies from this client's admin guide.

Use PowerShell for sensitivity labels and their policies

You can now use Security & Compliance Center PowerShell to create and configure all the settings you see in your labeling admin center. This means that in addition to using PowerShell for settings that aren't available in the labeling admin centers, you can now fully script the creation and maintenance of sensitivity labels and sensitivity label policies.

See the following documentation for supported parameters and values:

- New-Label
- New-LabelPolicy
- Set-Label

- Set-LabelPolicy

You can also use Remove-Label and Remove-LabelPolicy if you need to script the deletion of sensitivity labels or sensitivity label policies. However, before you delete sensitivity labels, make sure you read the following section.

Removing and deleting labels

In a production environment, it's unlikely that you will need to remove sensitivity labels from a label policy, or delete sensitivity labels. It's more likely that you might need to do one or either of these actions during an initial testing phase. Make sure you understand what happens when you do either of these actions.

Removing a label from a label policy is less risky than deleting it, and you can always add it back to a label policy later if needed:

- When you remove a label from a label policy so that the label is no longer published to the originally specified users, the next time the label policy is refreshed, users no longer see that label to select in their Office app. However, if the label has been applied to documents or emails, the label isn't removed from that content. Any encryption that was applied by the label remains and the underlying protection template remains published.
- For labels that are removed but have previously been applied to content, users who are using built-in labeling for Word, Excel, and PowerPoint, still see the applied label name on the status bar. Similarly, labels that are removed that were applied to SharePoint sites still display the label name in the **Sensitivity** column.

In comparison, when you delete a label:

- If the label applied encryption, the underlying protection template is archived so that previously protected content can still be opened. Because of this archived protection template, you won't be able to create a new label with the same name. Although it's possible to delete a protection template by using PowerShell, don't do this unless you're sure you don't need to open content that was encrypted with the archived template.
- For desktop apps: The label information in the metadata remains, but because a label ID to name mapping is no longer possible, users don't see the applied label name displayed (for example, on the status bar) so users will assume the content isn't labeled. If the label applied encryption, the encryption remains and when the content is opened, uses still see the name and description of the now archived protection template.
- For Office on the web: Users don't see the label name on status bar or in the **Sensitivity** column. The label information in the metadata remains only if the label didn't apply encryption. If the label applied encryption, and you've enabled sensitivity labels for SharePoint and OneDrive, the label information in the metadata is removed and the encryption is removed.

When you remove a sensitivity label from a label policy, or delete a sensitivity label, these changes can take up to one hour to replicate to all users and services.

Next steps

To configure and use your sensitivity labels for specific scenarios, use the following articles:

- Restrict access to content by using encryption in sensitivity labels
- Apply a sensitivity label to content automatically
- Use sensitivity labels with teams, groups, and sites
- Enable sensitivity labels for Office files in SharePoint and OneDrive

To monitor how your labels are being used, see Get started with data classification.

Restrict access to content by using sensitivity labels to apply encryption

2/18/2021 • 21 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

When you create a sensitivity label, you can restrict access to content that the label will be applied to. For example, with the encryption settings for a sensitivity label, you can protect content so that:

- Only users within your organization can open a confidential document or email.
- Only users in the marketing department can edit and print the promotion announcement document or email, while all other users in your organization can only read it.
- Users cannot forward an email or copy information from it that contains news about an internal reorganization.
- The current price list that is sent to business partners cannot be opened after a specified date.

When a document or email is encrypted, access to the content is restricted, so that it:

- Can be decrypted only by users authorized by the label's encryption settings.
- Remains encrypted no matter where it resides, inside or outside your organization, even if the file's renamed.
- Is encrypted both at rest (for example, in a OneDrive account) and in transit (for example, email as it traverses the internet).

Finally, as an admin, when you configure a sensitivity label to apply encryption, you can choose either to:

- **Assign permissions now**, so that you determine exactly which users get which permissions to content with that label.
- **Let users assign permissions** when they apply the label to content. This way, you can allow people in your organization some flexibility that they might need to collaborate and get their work done.

The encryption settings are available when you create a sensitivity label in the Microsoft 365 compliance center, Microsoft 365 security center, or the Security & Compliance Center.

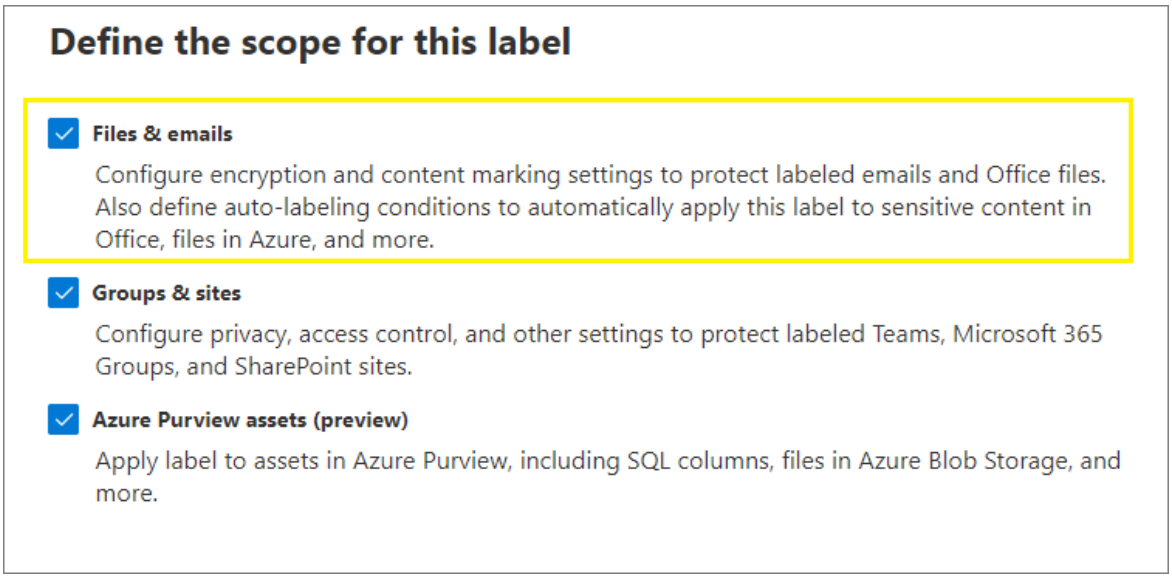
Understand how the encryption works

Encryption uses the Azure Rights Management service (Azure RMS) from Azure Information Protection. This protection solution uses encryption, identity, and authorization policies. To learn more, see What is Azure Rights Management? from the Azure Information Protection documentation.

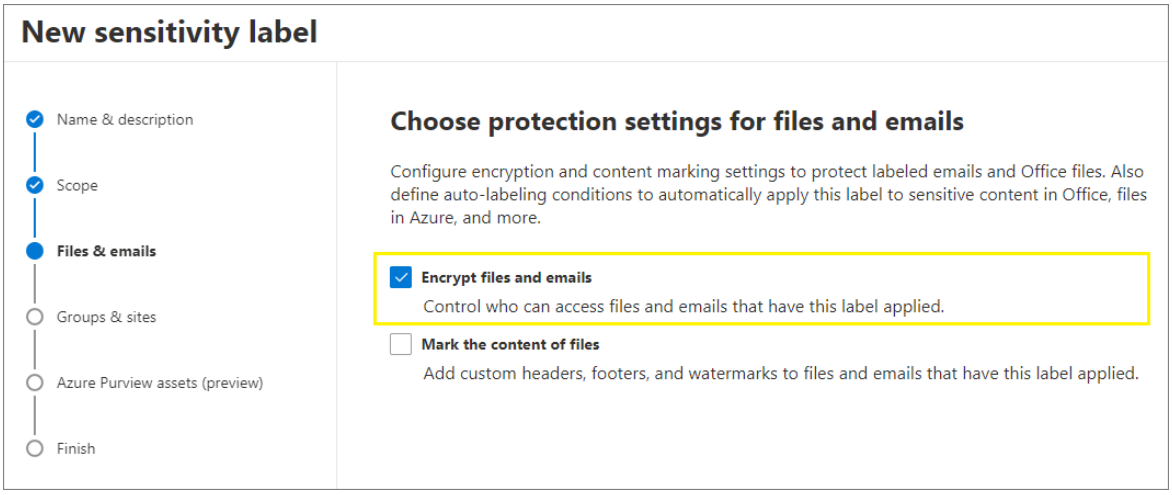
When you use this encryption solution, the **super user** feature ensures that authorized people and services can always read and inspect the data that has been encrypted for your organization. If necessary, the encryption can then be removed or changed. For more information, see Configuring super users for Azure Information Protection and discovery services or data recovery.

How to configure a label for encryption

1. Follow the general instructions to create or edit a sensitivity label and make sure **Files & emails** is selected for the label's scope:

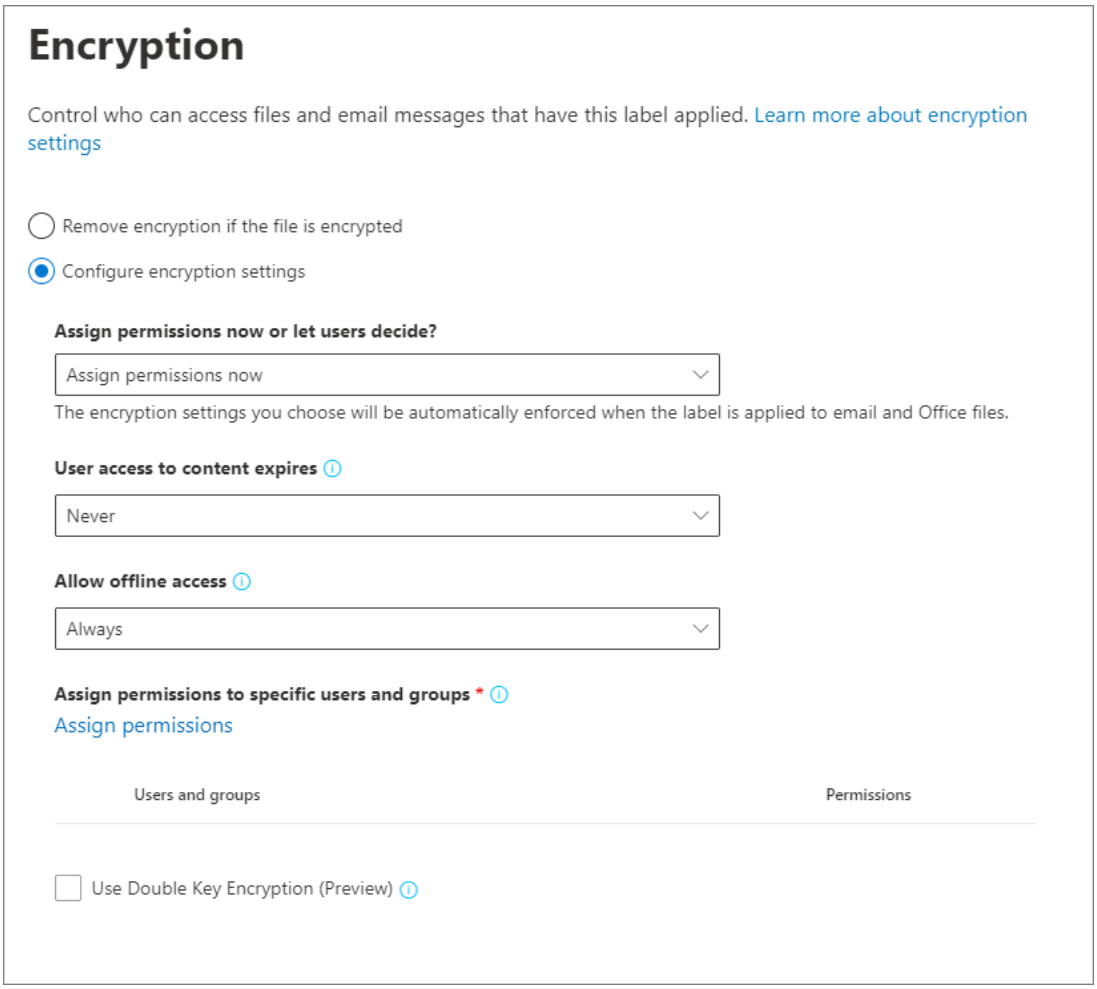


2. Then, on the **Choose protection settings for files and emails** page, make sure you select **Encrypt files and emails**



3. On the **Encryption** page of the wizard, select one of the following options:

   - **Remove encryption if the file is encrypted**: For more information about this scenario, see the What happens to existing encryption when a label's applied section. It's important to understand that this setting can result in a sensitivity label that users might not be able to apply when they don't have sufficient permissions.
   - **Configure encryption settings**: Turns on encryption and makes the encryption settings visible:



Instructions for these settings are in the following Configure encryption settings section.

What happens to existing encryption when a label's applied

If a sensitivity label is applied to unencrypted content, the outcome of the encryption options you can select is self-explanatory. For example, if you didn't select **Encrypt files and emails**, the content remains unencrypted.

However, the content might be already encrypted. For example, another user might have applied:

- Their own permissions, which include user-defined permissions when prompted by a label, custom permissions by the Azure Information Protection client, and the **Restricted Access** document protection from within an Office app.
- An Azure Rights Management protection template that encrypts the content independently from a label. This category includes mail flow rules that apply encryption by using rights protection.
- A label that applies encryption with permissions assigned by the administrator.

The following table identifies what happens to existing encryption when a sensitivity label is applied to that content:

	ENCRYPTION: NOT SELECTED	ENCRYPTION: CONFIGURED	ENCRYPTION: REMOVE
Permissions specified by a user	Original encryption is preserved	New label encryption is applied	Original encryption is removed
Protection template	Original encryption is preserved	New label encryption is applied	Original encryption is removed
Label with administator-defined permissions	Original encryption is removed	New label encryption is applied	Original encryption is removed

Note that in the cases where the new label encryption is applied or the original encryption is removed, this happens only if the user applying the label has a usage right or role that supports this action:

- The usage right Export or Full Control.
- The role of Rights Management issuer or Rights Management owner, or super user.

If the user doesn't have one of these rights or roles, the label can't be applied and so the original encryption is preserved. The user sees the following message: **You don't have permission to make this change to the sensitivity label. Please contact the content owner.**

For example, the person who applies Do Not Forward to an email message can relabel the thread to replace the encryption or remove it, because they are the Rights Management owner for the email. But with the exception of super users, recipients of this email can't relabel it because they don't have the required usage rights.

Email attachments for encrypted email messages

When an email message is encrypted by any method, any unencrypted Office documents that are attached to the email automatically inherit the same encryption settings.

Documents that are already encrypted and then added as attachments always preserve their original encryption.

Configure encryption settings

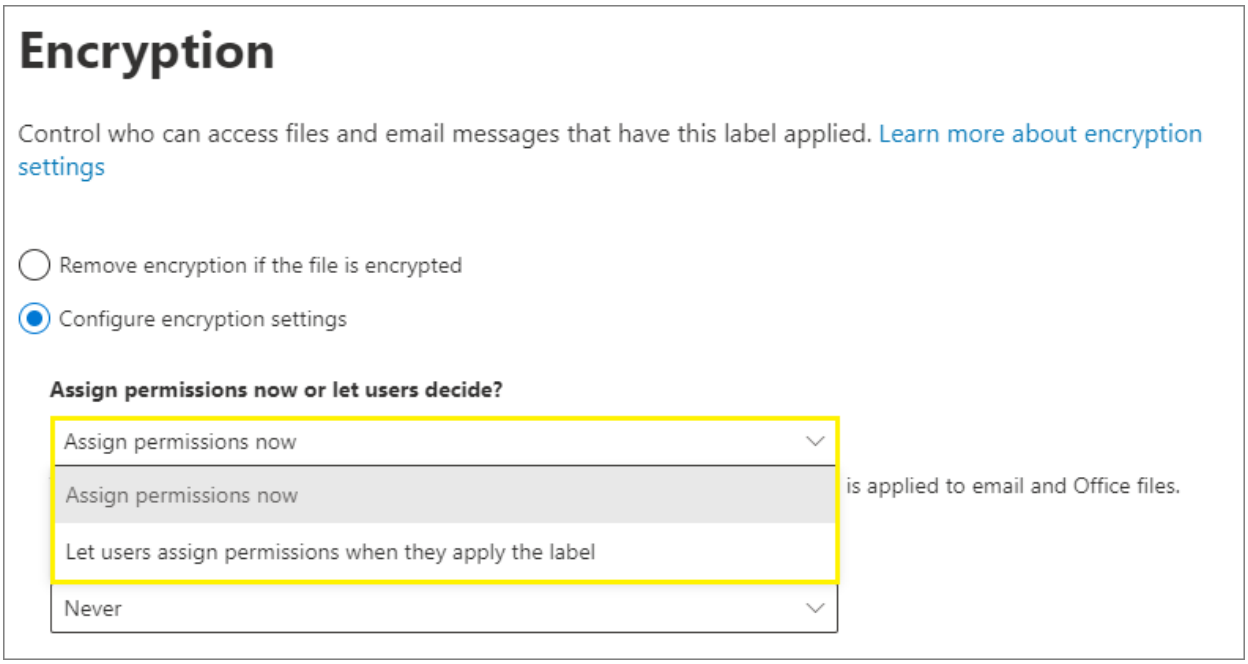
When you select **Configure encryption settings** on the **Encryption** page of the wizard to create or edit a sensitivity label, choose one of the following options:

- **Assign permissions now**, so that you can determine exactly which users get which permissions to content that has the label applied. For more information, see the next section Assign permissions now.
- **Let users assign permissions** when your users apply the label to content. With this option, you can allow people in your organization some flexibility that they might need to collaborate and get their work done. For more information, see the Let users assign permissions section on this page.

For example, if you have a sensitivity label named **Highly Confidential** that will be applied to your most sensitive content, you might want to decide now who gets what type of permissions to that content.

Alternatively, if you have a sensitivity label named **Business Contracts**, and your organization's workflow requires that your people collaborate on this content with different people on an ad hoc basis, you might want to allow your users to decide who gets permissions when they assign the label. This flexibility both helps your users' productivity and reduces the requests for your admins to update or create new sensitivity labels to address specific scenarios.

Choosing whether to assign permissions now or let users assign permissions:

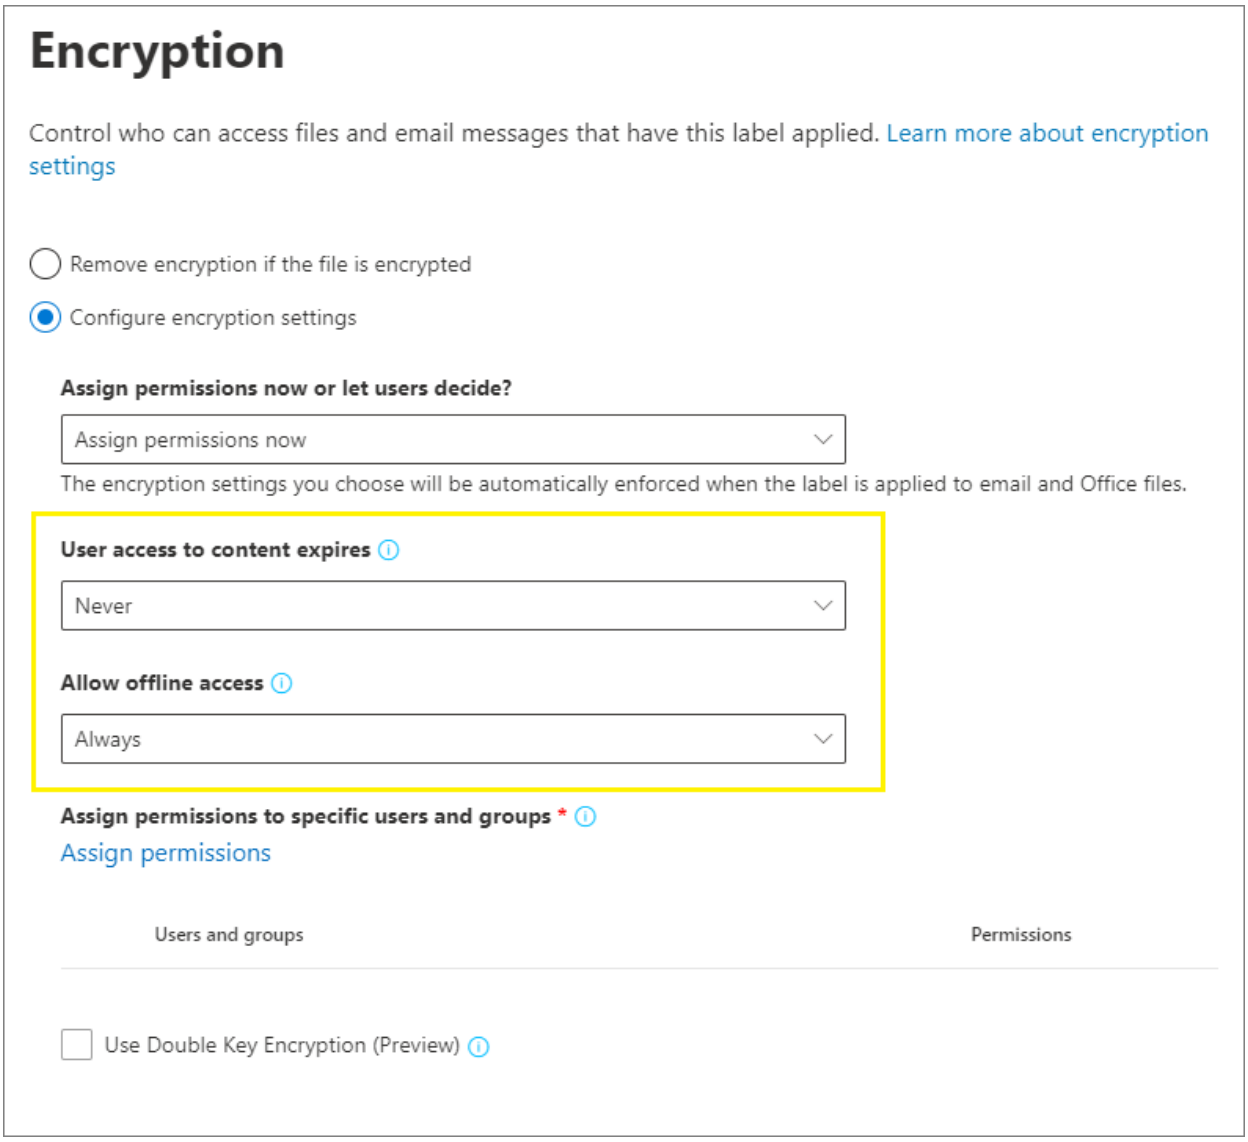


Assign permissions now

Use the following options to control who can access email or documents to which this label is applied. You can:

- **Allow access to labeled content to expire**, either on a specific date or after a specific number of days after the label is applied. After this time, users won't be able to open the labeled item. If you specify a date, it is effective midnight on that date in your current time zone. (Note that some email clients might not enforce expiration and show emails past their expiration date, due to their caching mechanisms.)
- **Allow offline access** never, always, or for a specific number of days after the label is applied. If you restrict offline access to never or a number of days, when that threshold is reached, users must be reauthenticated and their access is logged. For more information, see the next section on the Rights Management use license.

Settings for access control for encrypted content:



Rights Management use license for offline access

When a user opens a document or email that's been protected by encryption from the Azure Rights Management service, an Azure Rights Management use license for that content is granted to the user. This use license is a certificate that contains the user's usage rights for the document or email, and the encryption key that was used to encrypt the content. The use license also contains an expiration date if this has been set, and how long the use license is valid.

If no expiration date has been set, the default use license validity period for a tenant is 30 days. For the duration of the use license, the user is not reauthenticated or reauthorized for the content. This process lets the user continue to open the protected document or email without an internet connection. When the use license validity period expires, the next time the user accesses the protected document or email, the user must be reauthenticated and reauthorized.

In addition to reauthentication, the encryption settings and user group membership is reevaluated. This means that users could experience different access results for the same document or email if there are changes in the encryption settings or group membership from when they last accessed the content.

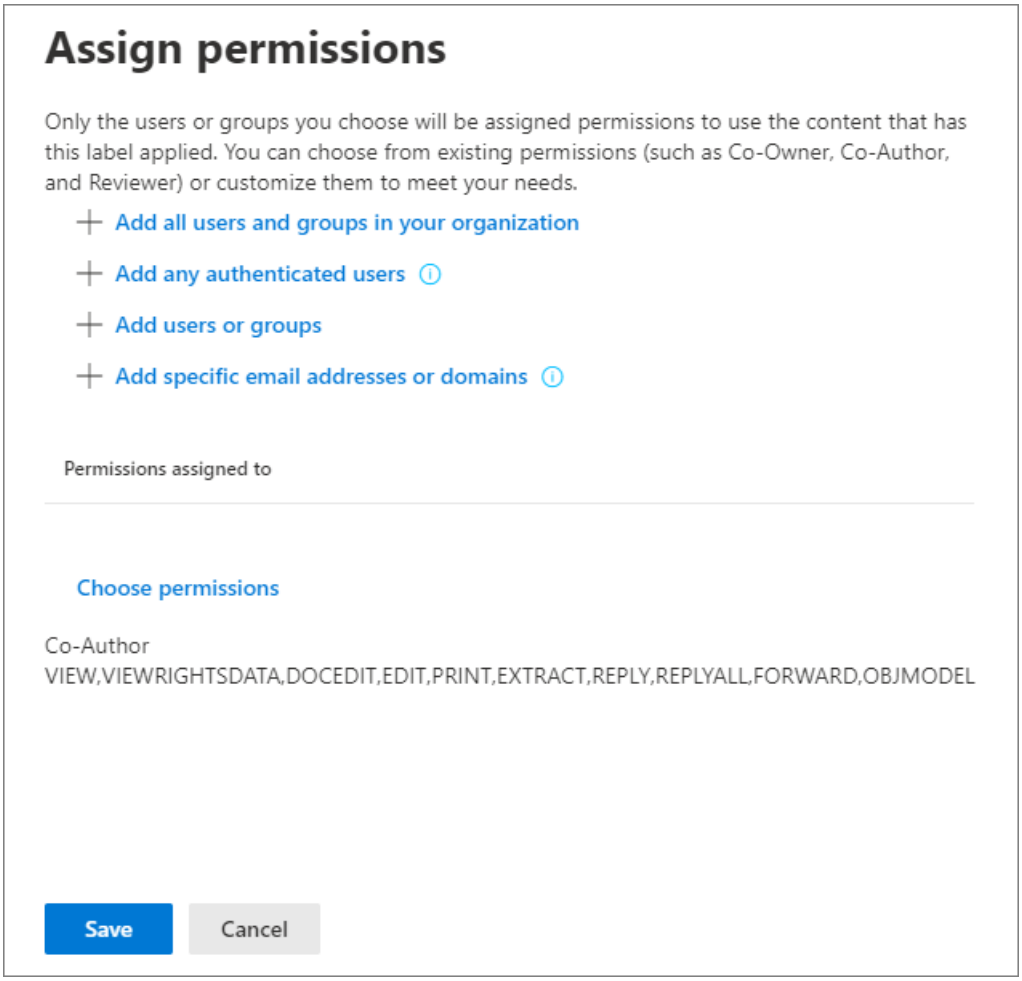
To learn how to change the default 30-day setting, see Rights Management use license.

Assign permissions to specific users or groups

You can grant permissions to specific people so that only they can interact with the labeled content:

1. First, add users or groups that will be assigned permissions to the labeled content.
2. Then, choose which permissions those users should have for the labeled content.

Assigning permissions:



Add users or groups

When you assign permissions, you can choose:

- Everyone in your organization (all tenant members). This setting excludes guest accounts.
- Any authenticated users. Make sure you understand the requirements and limitations of this setting before selecting it.
- Any specific user or email-enabled security group, distribution group, or Microsoft 365 group (formerly Office 365 group) in Azure AD. The Microsoft 365 group can have static or dynamic membership. Note that you can't use a dynamic distribution group from Exchange because this group type isn't synchronized to Azure AD, and you can't use a security group that isn't email-enabled.
- Any email address or domain. Use this option to specify all users in another organization who uses Azure AD, by entering any domain name from that organization. You can also use this option for social providers, by entering their domain name such as **gmail.com**, **hotmail.com**, or **outlook.com**.

  > **NOTE**
  > If you specify a domain from an organization that uses Azure AD, you can't restrict access to that specific domain. Instead, all verified domains in Azure AD are automatically included for the tenant that owns the domain name you specify.

When you choose all users and groups in your organization or browse the directory, the users or groups must have an email address.

As a best practice, use groups rather than users. This strategy keeps your configuration simpler.

Requirements and limitations for "Add any authenticated users"

This setting doesn't restrict who can access the content that the label encrypts, while still encrypting the content and providing you with options to restrict how the content can be used (permissions), and accessed (expiry and offline access). However, the application opening the encrypted content must be able to support the authentication being used. For this reason, federated social providers such as Google, and onetime passcode authentication work for email only, and only when you use Exchange Online. Microsoft accounts can be used with Office 365 apps and the Azure Information Protection viewer.

> **NOTE**
>
> Consider using this setting with SharePoint and OneDrive integration with Azure AD B2B when sensitivity labels are enabled for Office files in SharePoint and OneDrive.

Some typical scenarios for any authenticated users setting:

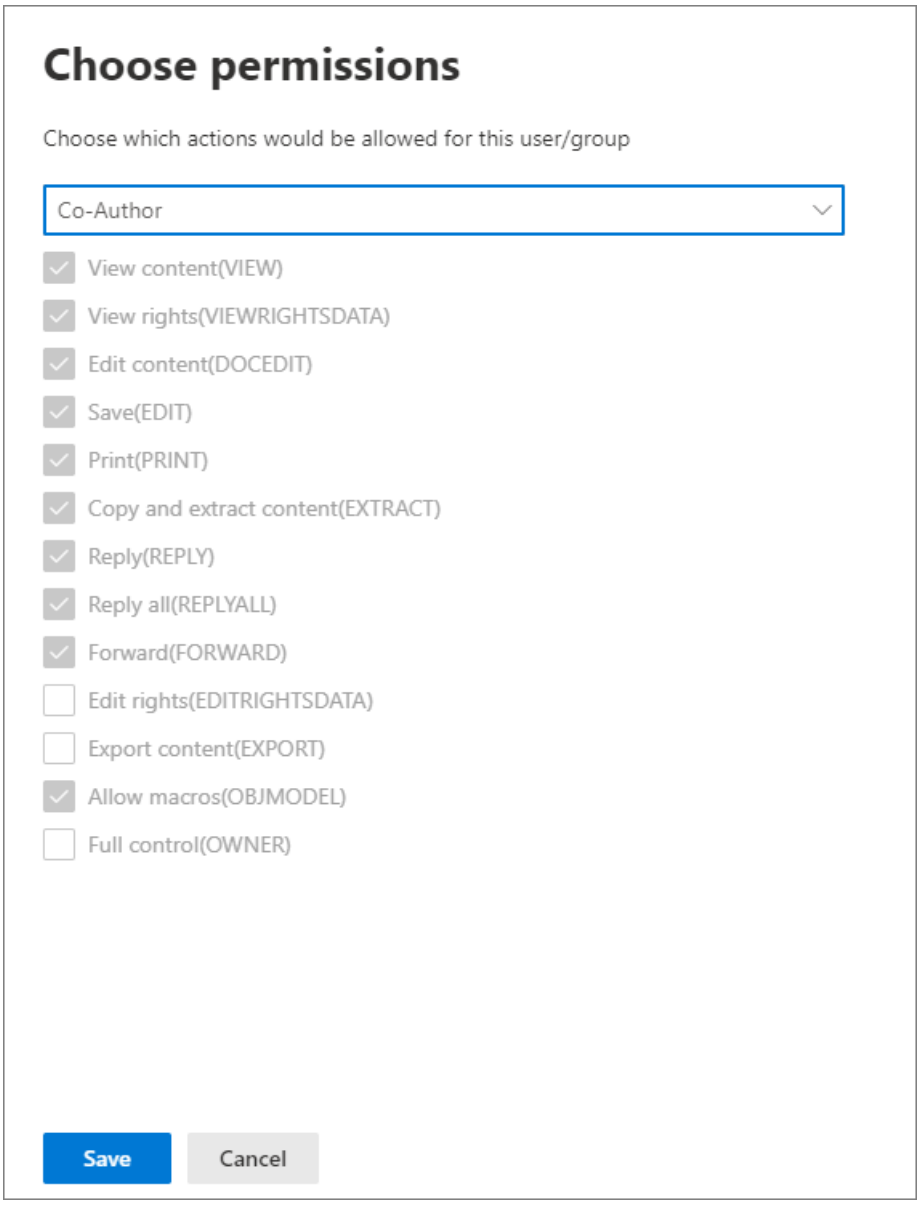
- You don't mind who views the content, but you want to restrict how it is used. For example, you don't want the content to be edited, copied, or printed.
- You don't need to restrict who accesses the content, but you want to be able to confirm who opens it.
- You have a requirement that the content must be encrypted at rest and in transit, but it doesn't require access controls.

Choose permissions

When you choose which permissions to allow for those users or groups, you can select either:

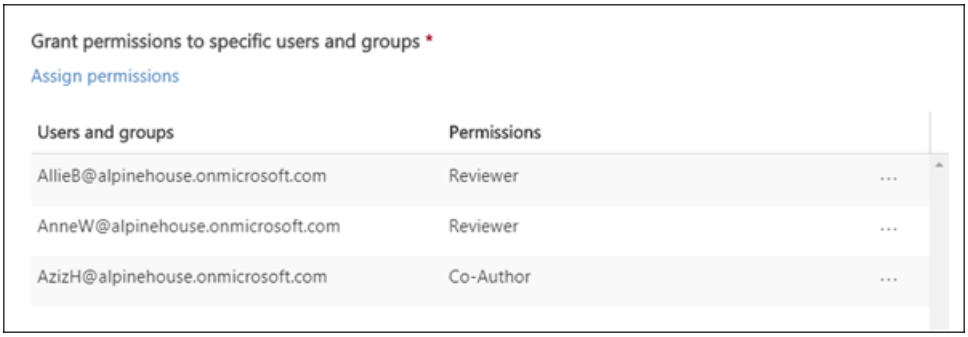
- A predefined permissions level with a preset group of rights, such as Co-Author or Reviewer.
- Custom permissions, where you choose one or more usage rights.

For more information to help you select the appropriate permissions, see Usage rights and descriptions.



Note that the same label can grant different permissions to different users. For example, a single label can assign some users as Reviewer and a different user as Co-author, as shown in the following screenshot.

To do this, add users or groups, assign them permissions, and save those settings. Then repeat these steps, adding users and assigning them permissions, saving the settings each time. You can repeat this configuration as often as necessary, to define different permissions for different users.



Rights Management issuer (user applying the sensitivity label) always has Full Control

Encryption for a sensitivity label uses the Azure Rights Management service from Azure Information Protection. When a user applies a sensitivity label to protect a document or email by using encryption, that user becomes the Rights Management issuer for that content.

The Rights Management issuer is always granted Full Control permissions for the document or email, and in addition:

- If the encryption settings include an expiration date, the Rights Management issuer can still open and edit the document or email after that date.
- The Rights Management issuer can always access the document or email offline.
- The Rights Management issuer can still open a document after it is revoked.

For more information, see Rights Management issuer and Rights Management owner.

Double Key Encryption

> **NOTE**
> This feature is currently supported only by the Azure Information Protection unified labeling client.

Select this option only after you have configured the Double Key Encryption service and you need to use this double key encryption for files that will have this label applied.

For more information, prerequisites, and configuration instructions, see Double Key Encryption (DKE).

Let users assign permissions

You can use these options to let users assign permissions when they manually apply a sensitivity label to content:

- In Outlook, a user can select restrictions equivalent to the Do Not Forward option for their chosen recipients.
- In Word, PowerPoint, and Excel, a user is prompted to select their own permissions for specific users, groups, or organizations.

  > **NOTE**
  > This option for Word, PowerPoint, and Excel is supported by the Azure Information Protection unified labeling client. For apps that use built-in labeling, check which apps support it.
  >
  > If this option is selected but isn't supported for a user's app, either that label doesn't display to the user, or the label displays for consistency, but it can't be applied with an explanation message to users.

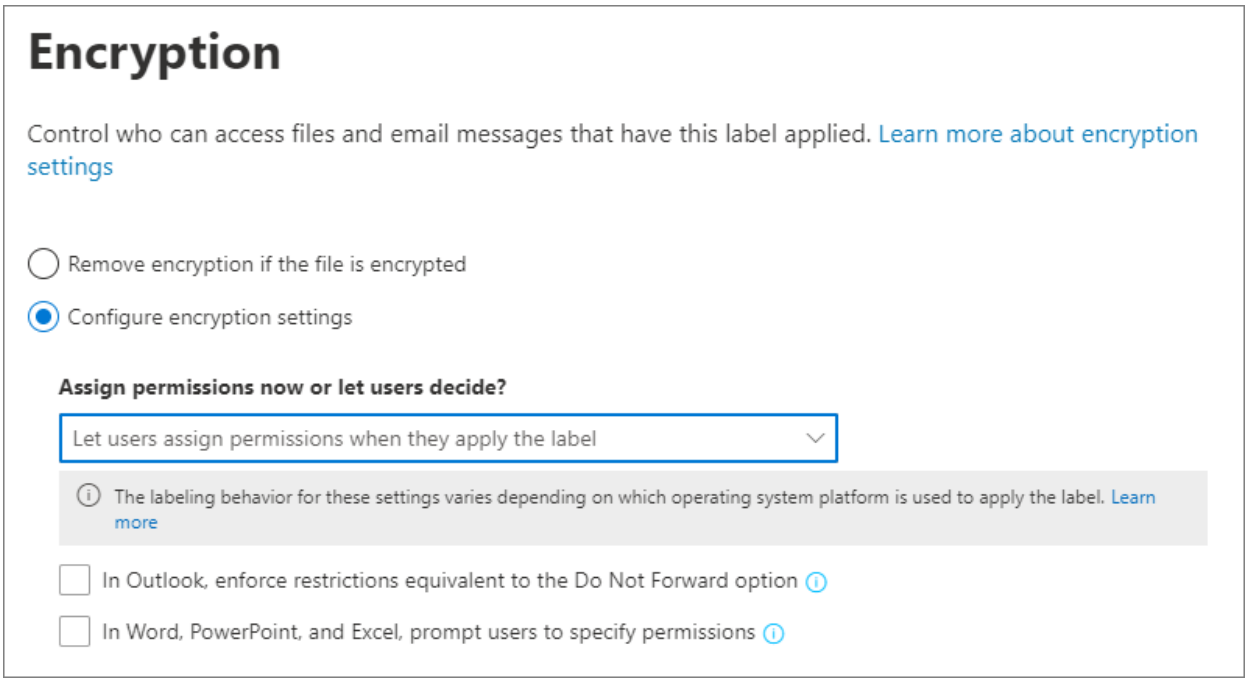
When the options are supported, use the following table to identify when users see the sensitivity label:

SETTING	LABEL VISIBLE IN OUTLOOK	LABEL VISIBLE IN WORD, EXCEL, POWERPOINT
In Outlook, enforce restrictions equivalent to the Do Not Forward option	Yes	No
In Word, PowerPoint, and Excel, prompt users to specify permissions	No	Yes

When both settings are selected, the label is therefore visible in both Outlook and in Word, Excel, and PowerPoint.

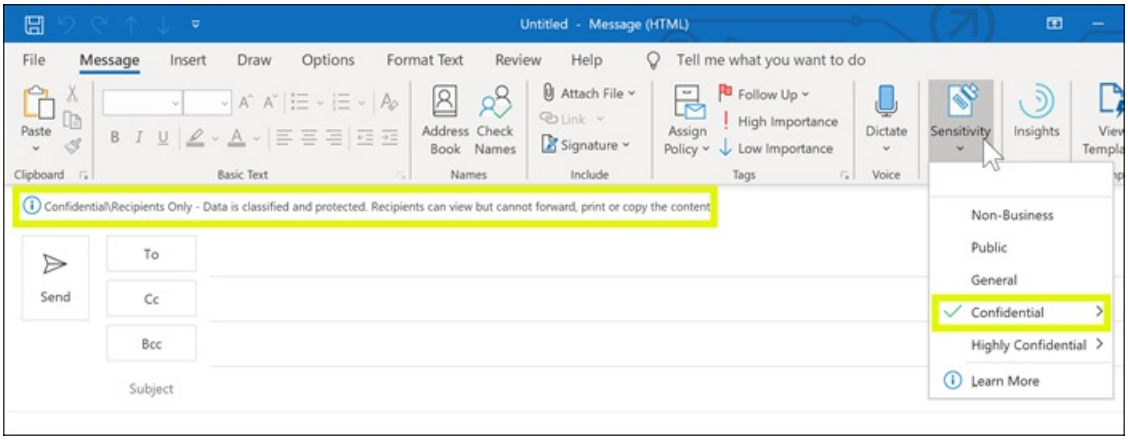
A sensitivity label that lets users assign permissions can be applied to content only manually by users; it can't be auto-applied or used as a recommended label.

Configuring the user-assigned permissions:



Outlook restrictions

In Outlook, when a user applies a sensitivity label that lets them assign permissions to a message, the restrictions are the same as the Do Not Forward option. The user will see the label name and description at the top of the message, which indicates the content's being protected. Unlike Word, PowerPoint, and Excel (see the next section), users aren't prompted to select specific permissions.



When the Do Not Forward option is applied to an email, the email is encrypted and recipients must be authenticated. Then, the recipients cannot forward it, print it, or copy from it. For example, in the Outlook client, the Forward button is not available, the Save As and Print menu options are not available, and you cannot add or change recipients in the To, Cc, or Bcc boxes.

Unencrypted Office documents that are attached to the email automatically inherit the same restrictions. The usage rights applied to these documents are Edit Content, Edit; Save; View, Open, Read; and Allow Macros. If the user wants different usage rights for an attachment, or the attachment is not an Office document that supports this inherited protection, the user needs to protect the file before attaching it to the email.

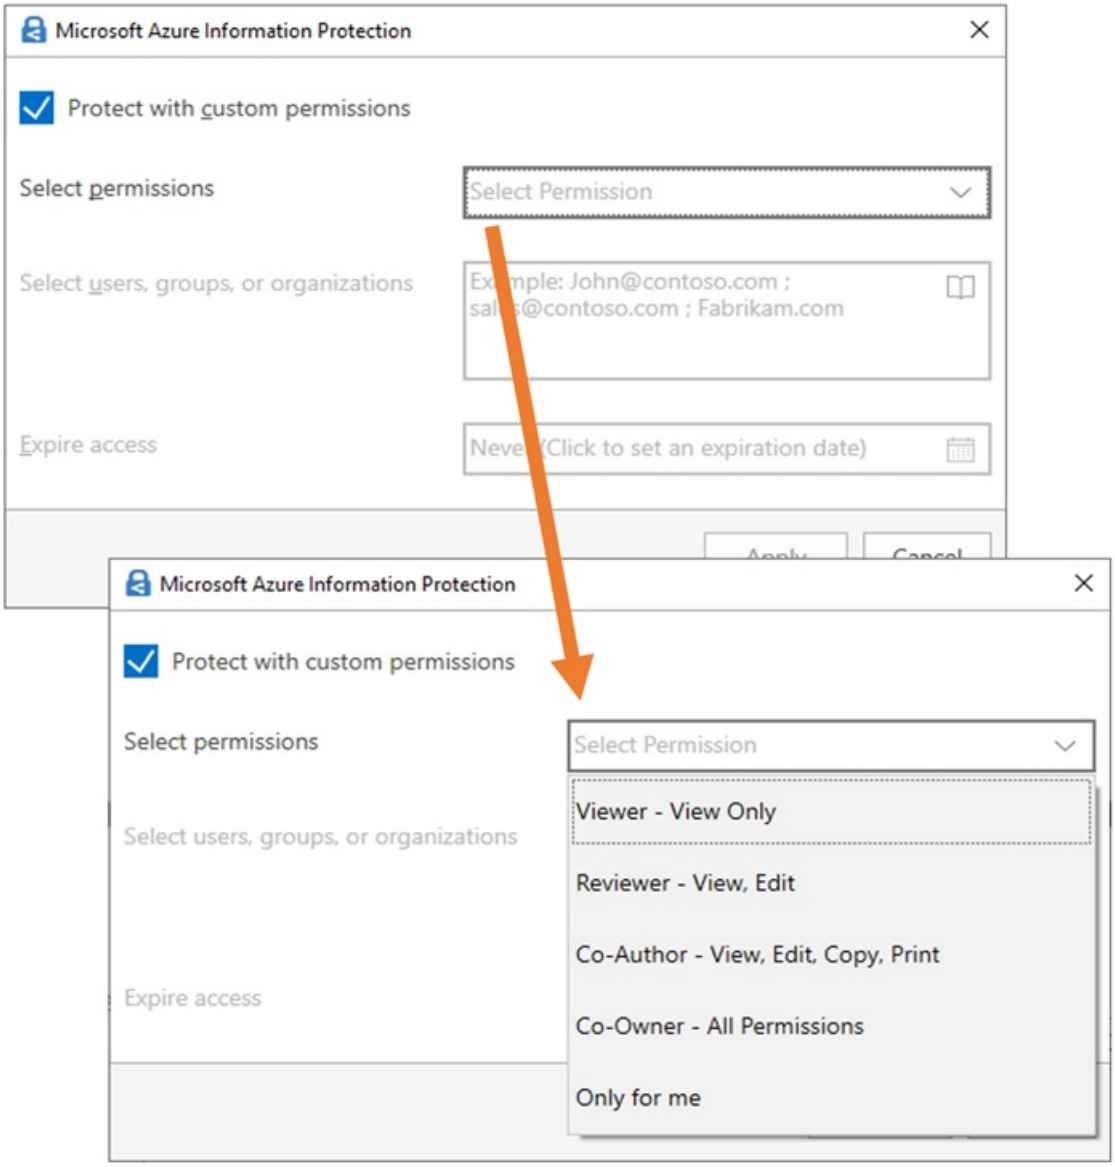
Word, PowerPoint, and Excel permissions

In Word, PowerPoint, and Excel, when a user applies a sensitivity label that lets them assign permissions to a document, they are prompted to specify their choice of users and permissions when the encryption is applied.

For example, with the Azure Information Protection unified labeling client, users can:

- Select a permission level, such as Viewer (which assigns View Only permission) or Co-Author (which assigns View, Edit, Copy, and Print permissions).

- Select users, groups, or organizations. This can include people both inside or outside your organizations.
- Set an expiration date, after which the selected users cannot access the content. For more information, see the above section Rights Management use license for offline access.

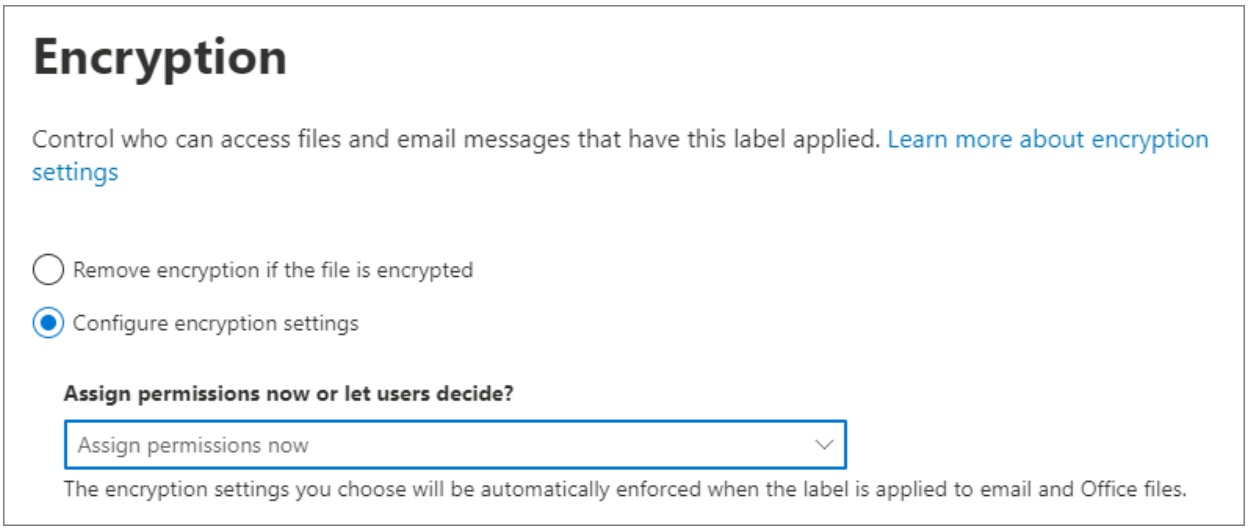


For built-in labeling, users see the same dialog box if they select the following:

- Windows: **File** tab > **Info** > **Protect Document** > **Restrict Access** > **Restricted Access**
- macOS: **Review** tab > **Protection** > **Permissions** > **Restricted Access**

Example configurations for the encryption settings

For each example that follows, do the configuration from the **Encryption** page of the wizard when **Configure encryption settings** is selected:



Example 1: Label that applies Do Not Forward to send an encrypted email to a Gmail account

This label displays only in Outlook and Outlook on the web, and you must use Exchange Online. Instruct users to select this label when they need to send an encrypted email to people using a Gmail account (or any other email account outside your organization).

Your users type the Gmail email address in the **To** box. Then, they select the label and the Do Not Forward option is automatically added to the email. The result is that recipients cannot forward the email, or print it, copy from it, or save the email outside their mailbox by using the **Save As** option.

1. On the **Encryption** page: For **Assign permissions now or let users decide?** select **Let users assign permissions when they apply the label**.
2. Select the checkbox: **In Outlook, enforce restrictions equivalent to the Do Not Forward option**.
3. If selected, clear the checkbox: **In Word, PowerPoint, and Excel, prompt users to specify permissions**.
4. Select **Next** and complete the wizard.

Example 2: Label that restricts read-only permission to all users in another organization

This label is suitable for sharing very sensitive documents as read-only, and the documents always require an internet connection to view them.

This label is not suitable for emails.

1. On the **Encryption** page: For **Assign permissions now or let users decide?** select **Assign permissions now**.
2. For **Allow offline access**, select **Never**.
3. Select **Assign permissions**.
4. On the **Assign permissions** pane, select **Add specific email addresses or domains**.
5. In the text box, enter the name of a domain from the other organization, for example, **fabrikam.com**. Then select **Add**.
6. Select **Choose permissions**.
7. On the **Choose permissions** pane, select the dropdown box, select **Viewer**, and then select **Save**.
8. Back on the **Assign Permissions** pane, select **Save**.
9. On the **Encryption** page, select **Next** and complete the wizard.

Example 3: Add external users to an existing label that encrypts content

The new users that you add will be able open documents and emails that have already been protected with this label. The permissions that you grant these users can be different from the permissions that the existing users have.

1. On the **Encryption** page: For **Assign permissions now or let users decide?** make sure **Assign permissions now** is selected.
2. Select **Assign permissions**.
3. On the **Assign permissions** pane, select **Add specific email addresses or domains**.
4. In the text box, enter the email address of the first user (or group) to add, and then select **Add**.
5. Select **Choose permissions**.
6. On the **Choose permissions** pane, select the permissions for this user (or group), and then select **Save**.
7. Back on the **Assign Permissions** pane, repeat steps 3 through 6 for each user (or group) that you want to add to this label. Then click **Save**.
8. On the **Encryption** page, select **Next** and complete the wizard.

Example 4: Label that encrypts content but doesn't restrict who can access it

This configuration has the advantage that you don't need to specify users, groups, or domains to encrypt an email or document. The content will still be encrypted and you can still specify usage rights, an expiry date, and offline access.

Use this configuration only when you do not need to restrict who can open the protected document or email. More information about this setting

1. On the **Encryption** page: For **Assign permissions now or let users decide?** make sure **Assign permissions now** is selected.
2. Configure settings for **User access to content expires** and **Allow offline access** as required.
3. Select **Assign permissions**.
4. On the **Assign permissions** pane, select **Add any authenticated users**.

   For **Users and groups**, you see **Authenticated users** automatically added. You can't change this value, only delete it, which cancels the **Add any authenticated users** selection.
5. Select **Choose permissions**.
6. On the **Choose permissions** pane, select the dropdown box, select the permissions you want, and then select **Save**.
7. Back on the **Assign Permissions** pane, select **Save**.
8. On the **Encryption** page, select **Next** and complete the wizard.

Considerations for encrypted content

Encrypting your most sensitive documents and emails helps to ensure that only authorized people can access this data. However, there are some considerations to take into account:

- If your organization hasn't enabled sensitivity labels for Office files in SharePoint and OneDrive:
  - Search, eDiscovery, and Delve will not work for encrypted files.
  - DLP policies work for the metadata of these encrypted files (including retention label information) but

not the content of these files (such as credit card numbers within files).
    - Users can't open encrypted files using Office on the web. When sensitivity labels for Office files in SharePoint and OneDrive are enabled, users can use Office on the web to open encrypted files, with some limitations that include encryption that has been applied with an on-premises key (known as "hold your own key", or HYOK), double key encryption, and encryption that has been applied independently from a sensitivity label.
- If you share encrypted documents with people outside your organization, you might need to create guest accounts and modify Conditional Access policies. For more information, see Sharing encrypted documents with external users.
- For multiple users to edit an encrypted file at the same time, they must all be using Office for the web. If this isn't the case, and the file is already open:
    - In Office apps (Windows, Mac, Android, and iOS), users see a **File In Use** message with the name of the person who has checked out the file. They can then view a read-only copy or save and edit a copy of the file, and receive notification when the file is available.
    - In Office for the web, users see an error message that they can't edit the document with other people. They can then select **Open in Reading View**.
- The AutoSave functionality in Office apps (Windows, Mac, Android, and iOS) is disabled for encrypted files. Users see a message that the file has restricted permissions that must be removed before AutoSave can be turned on.
- Encrypted files might take longer to open in Office apps (Windows, Mac, Android, and iOS).
- If a label that applies encryption is added by using an Office app when the document is checked out in SharePoint, and the user then discards the checkout, the document remains labeled and encrypted.
- The following actions for encrypted files aren't supported from Office apps (Windows, Mac, Android, and iOS), and users see an error message that something went wrong. However, SharePoint functionality can be used as an alternative:
    - View, restore, and save copies of previous versions. As an alternative, users can do these actions using Office on the web when you enable and configure versioning for a list or library.
    - Change the name or location of files. As an alternative, users can rename a file, folder, or link in a document library in SharePoint.

For the best collaboration experience for files that are encrypted by a sensitivity label, we recommend you use sensitivity labels for Office files in SharePoint and OneDrive and Office for the web.

Important prerequisites

Before you can use encryption, you might need to do some configuration tasks.

- Activate protection from Azure Information Protection

  For sensitivity labels to apply encryption, the protection service (Azure Rights Management) from Azure Information Protection must be activated for your tenant. In newer tenants, this is the default setting, but you might need to manually activate the service. For more information, see Activating the protection service from Azure Information Protection.

- Configure Exchange for Azure Information Protection

  Exchange does not have to be configured for Azure Information Protection before users can apply labels in Outlook to encrypt their emails. However, until Exchange is configured for Azure Information Protection, you do not get the full functionality of using Azure Rights Management protection with Exchange.

For example, users cannot view encrypted emails on mobile phones or with Outlook on the web, encrypted emails cannot be indexed for search, and you cannot configure Exchange Online DLP for Rights Management protection.

To ensure that Exchange can support these additional scenarios, see the following:

- For Exchange Online, see the instructions for Exchange Online: IRM Configuration.
- For Exchange on-premises, you must deploy the RMS connector and configure your Exchange servers.

Next steps

Need to share your labeled and encrypted documents with people outside your organization? See Sharing encrypted documents with external users.

Apply a sensitivity label to content automatically

2/18/2021 • 17 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

NOTE

For information about automatically applying a sensitivity label in Azure Purview (preview), see Automatically label your content in Azure Purview.

When you create a sensitivity label, you can automatically assign that label to files and emails when it matches conditions that you specify.

This ability to apply sensitivity labels to content automatically is important because:

- You don't need to train your users when to use each of your classifications.
- You don't need to rely on users to classify all content correctly.
- Users no longer need to know about your policies—they can instead focus on their work.

When content has been manually labeled, that label will never be replaced by automatic labeling. However, automatic labeling can replace a lower priority label that was automatically applied.

There are two different methods for automatically applying a sensitivity label to content in Microsoft 365:

- **Client-side labeling when users edit documents or compose (also reply or forward) emails**: Use a label that's configured for auto-labeling for files and emails (includes Word, Excel, PowerPoint, and Outlook).

  This method supports recommending a label to users, as well as automatically applying a label. But in both cases, the user decides whether to accept or reject the label, to help ensure the correct labeling of content. This client-side labeling has minimal delay for documents because the label can be applied even before the document is saved. However, not all client apps support auto-labeling. This capability is supported by the Azure Information Protection unified labeling client, and some versions of Office.

  For configuration instructions, see How to configure auto-labeling for Office apps on this page.

- **Service-side labeling when content is already saved (in SharePoint or OneDrive) or emailed (processed by Exchange Online)**: Use an auto-labeling policy.

  You might also hear this method referred to as auto-labeling for data at rest (documents in SharePoint and OneDrive) and data in transit (email that is sent or received by Exchange). For Exchange, it doesn't include emails at rest (mailboxes).

  Because this labeling is applied by services rather than by applications, you don't need to worry about what apps users have and what version. As a result, this capability is immediately available throughout your organization and suitable for labeling at scale. Auto-labeling policies don't support recommended labeling because the user doesn't interact with the labeling process. Instead, the administrator runs the policies in simulation mode to help ensure the correct labeling of content before actually applying the label.

  For configuration instructions, see How to configure auto-labeling policies for SharePoint, OneDrive, and

Exchange on this page.

Specific to auto-labeling for SharePoint and OneDrive:

- Office files for Word, PowerPoint, and Excel are supported. Open XML format is supported (such as .docx and .xlsx) but not Microsoft Office 97-2003 format (such as .doc and .xls).
  - These files can be auto-labeled when they are not part of an open session and whether they have been created, uploaded, or changed since you created auto-labeling policies, or they are existing files that have not been changed since you created your auto-labeling policies.
- Maximum of 25,000 automatically labeled files in your tenant per day.
- Maximum of 10 auto-labeling policies per tenant, each targeting up to 10 sites (SharePoint or OneDrive).
- Existing values for modified, modified by, and the date are not changed as a result of auto-labeling policies—for both simulation mode and when labels are applied.
- When the label applies encryption, the Rights Management issuer and Rights Management owner is the account that last modified the file.

Specific to auto-labeling for Exchange:

- Unlike manual labeling or auto-labeling with Office apps, Office attachments (Word, Excel, and PowerPoint files) and PDF attachments are also scanned for the conditions you specify in your auto-labeling policy. When there is a match, the email is labeled but not the attachment.
  - For these Office files, Open XML format is supported (such as .docx and .xlsx) but not Microsoft Office 97-2003 format (such as .doc and .xls).
- If you have Exchange mail flow rules or data loss prevention (DLP) policies that apply IRM encryption: When content is identified by these rules or policies and an auto-labeling policy, the label is applied. If that label applies encryption, the IRM settings from the Exchange mail flow rules or DLP policies are ignored. However, if that label doesn't apply encryption, the IRM settings from the mail flow rules or DLP policies are applied in addition to the label.
- Email that has IRM encryption with no label will be replaced by a label with any encryption settings when there is a match by using auto-labeling.
- Incoming email is labeled when there is a match with your auto-labeling conditions. However, if the label is configured for encryption, that encryption isn't applied.
- When the label applies encryption, the Rights Management issuer and Rights Management owner is the person who sends the email.

Compare auto-labeling for Office apps with auto-labeling policies

Use the following table to help you identify the differences in behavior for the two complementary automatic labeling methods:

FEATURE OR BEHAVIOR	LABEL SETTING: AUTO-LABELING FOR FILES AND EMAILS	POLICY: AUTO-LABELING
App dependency	Yes	No *
Restrict by location	No	Yes
Conditions: Trainable classifiers	Yes	No
Conditions: Sharing options and additional options for email	No	Yes

FEATURE OR BEHAVIOR	LABEL SETTING: AUTO-LABELING FOR FILES AND EMAILS	POLICY: AUTO-LABELING
Recommendations, policy tooltip, and user overrides	Yes	No
Simulation mode	No	Yes
Exchange attachments checked for conditions	No	Yes
Apply visual markings	Yes	Yes (email only)
Override IRM encryption applied without a label	Yes if the user has the minimum usage right of Export	Yes (email only)
Label incoming email	No	Yes (encryption not applied)

* Auto-labeling isn't currently available in all regions. If your tenant can't support this functionality, the Auto-labeling tab isn't visible in the admin labeling center.

How multiple conditions are evaluated when they apply to more than one label

The labels are ordered for evaluation according to their position that you specify in the policy: The label positioned first has the lowest position (least sensitive) and the label positioned last has the highest position (most sensitive). For more information on priority, see Label priority (order matters).

Don't configure a parent label to be applied automatically or recommended

Remember, you can't apply a parent label (a label with sublabels) to content. Make sure that you don't configure a parent label to be auto-applied or recommended in Office apps, and don't select a parent label for an auto-labeling policy. If you do, the parent label won't be applied to content.

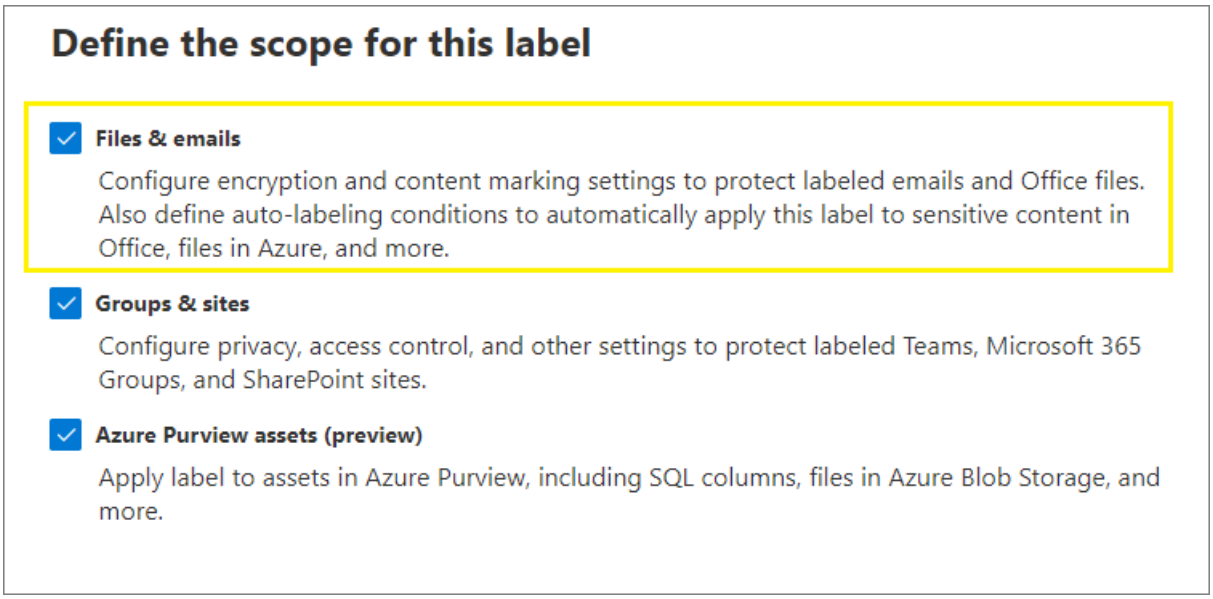
To use automatic labeling with sublabels, make sure you publish both the parent label and the sublabel.

For more information on parent labels and sublabels, see Sublabels (grouping labels).

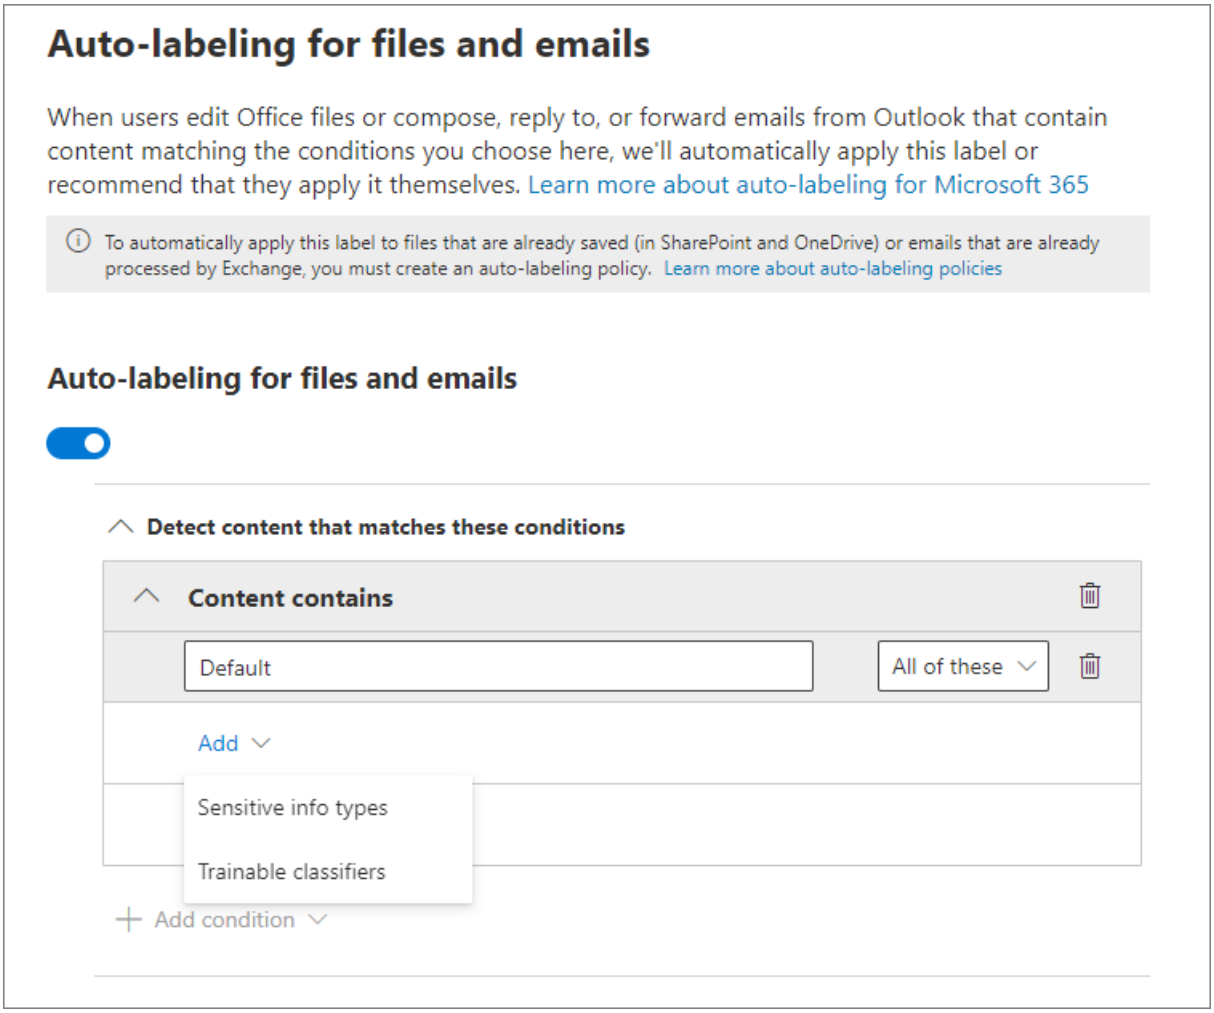
How to configure auto-labeling for Office apps

Automatic labeling in Office apps for Windows is supported by the Azure Information Protection unified labeling client. For built-in labeling in Office apps, this capability is in different stages of availability for different apps.

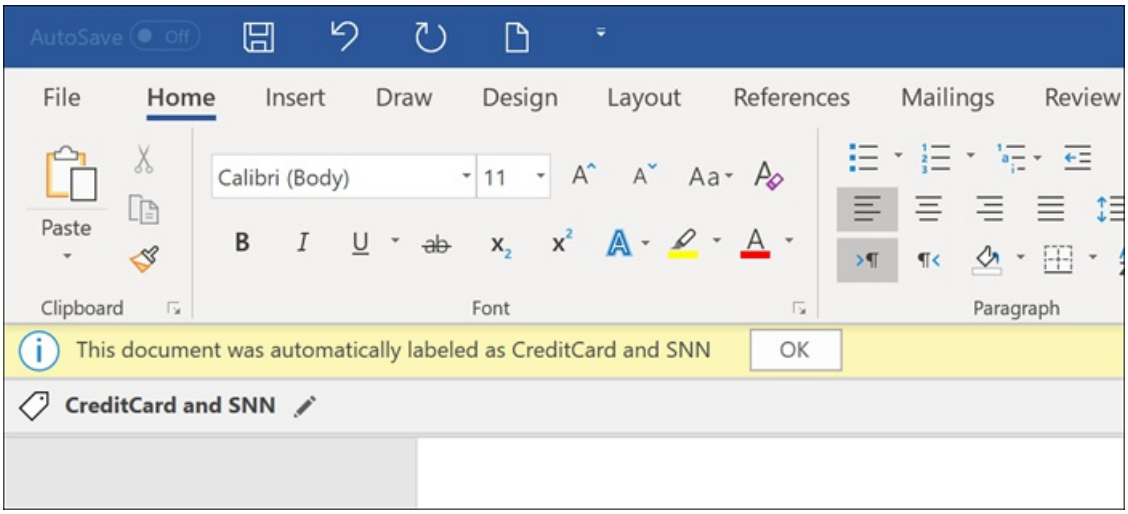
The auto-labeling settings for Office apps are available when you create or edit a sensitivity label. Make sure **Files & emails** is selected for the label's scope:



As you move through the wizard, you see the **Auto-labeling for files and emails** page where you can choose from a list of sensitive info types or trainable classifiers:

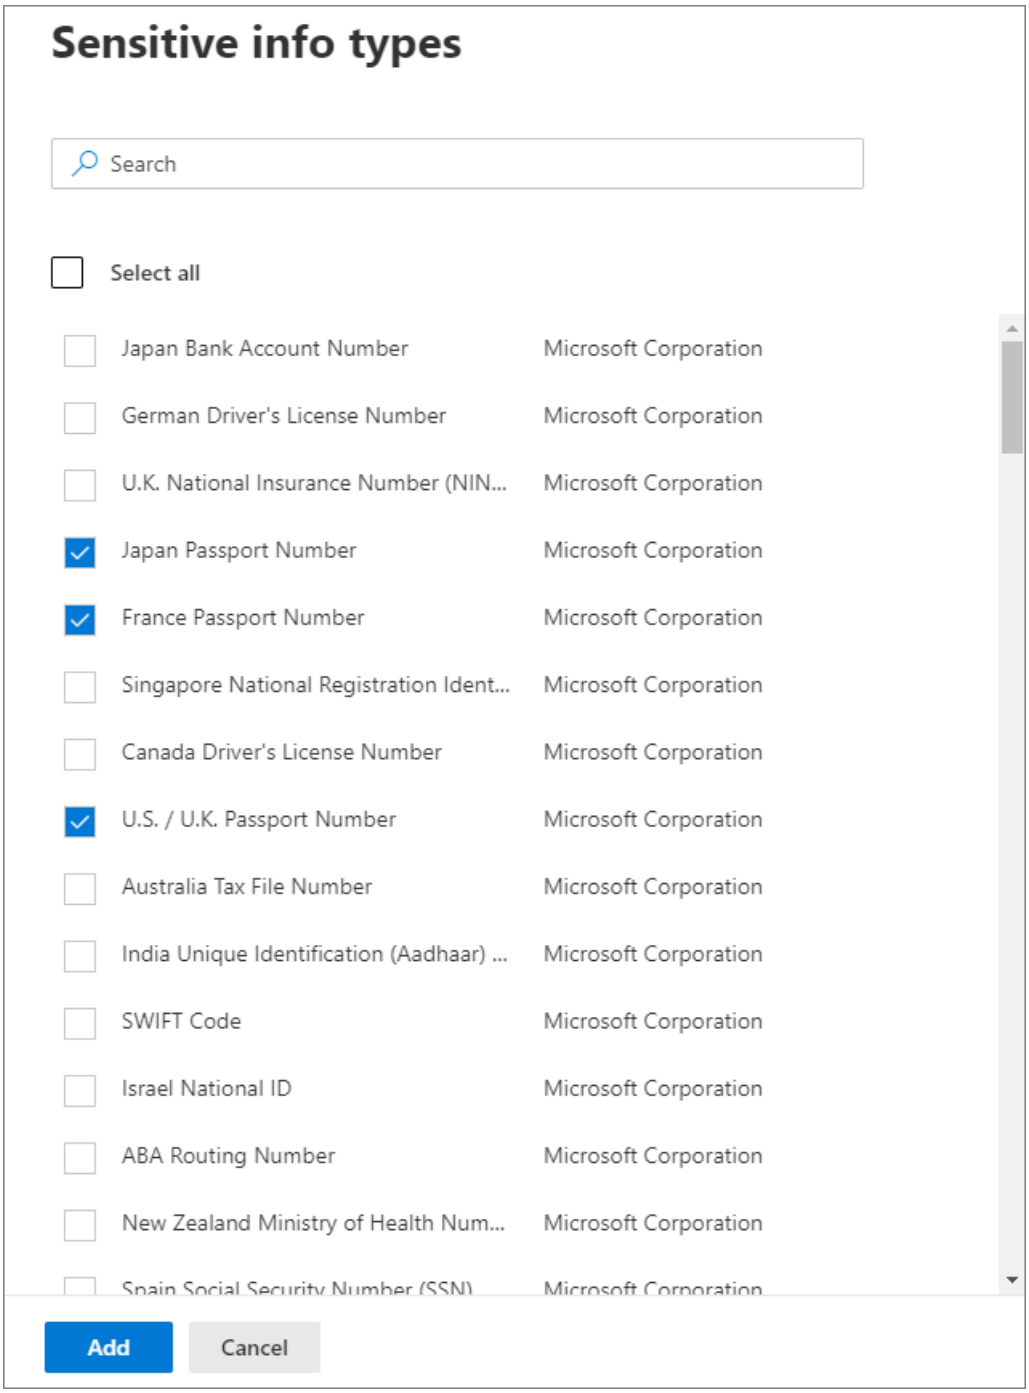


When this sensitivity label is automatically applied, the user sees a notification in their Office app. For example:

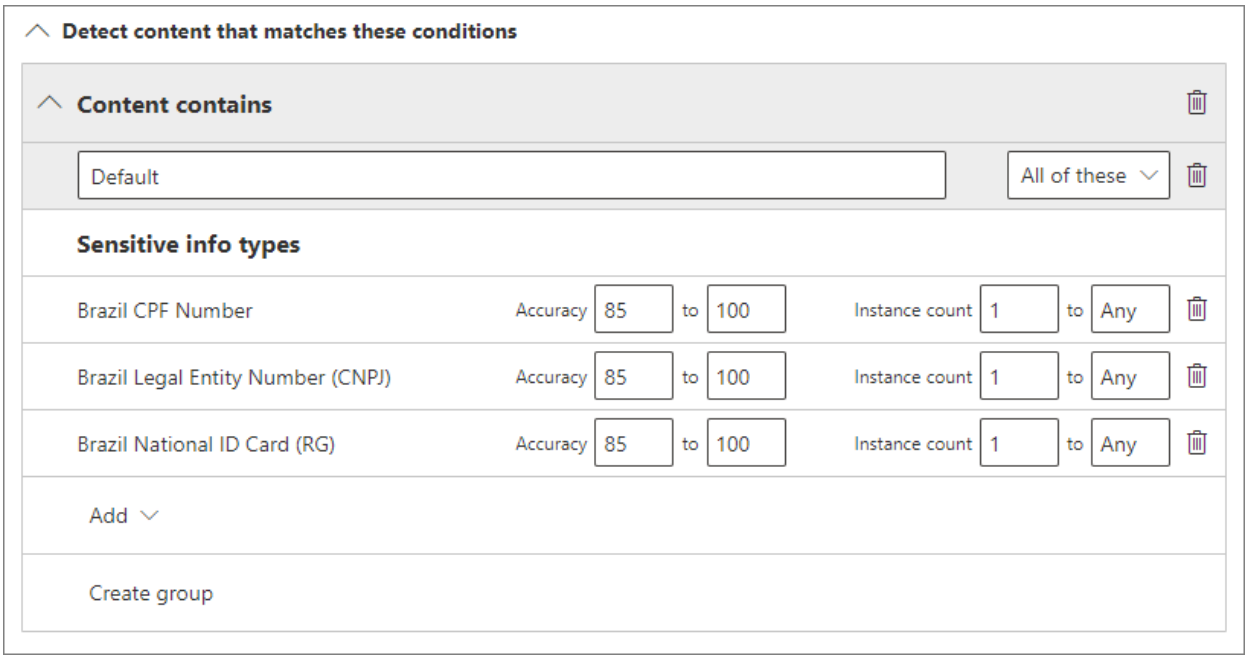


Configuring sensitive info types for a label

When you select the **Sensitive info types** option, you see the same list of sensitive information types as when you create a data loss prevention (DLP) policy. So you can, for example, automatically apply a Highly Confidential label to any content that contains customers' personal information, such as credit card numbers, social security numbers, or passport numbers:



Similarly to when you configure DLP policies, you can then refine your condition by changing the instance count and match accuracy. For example:



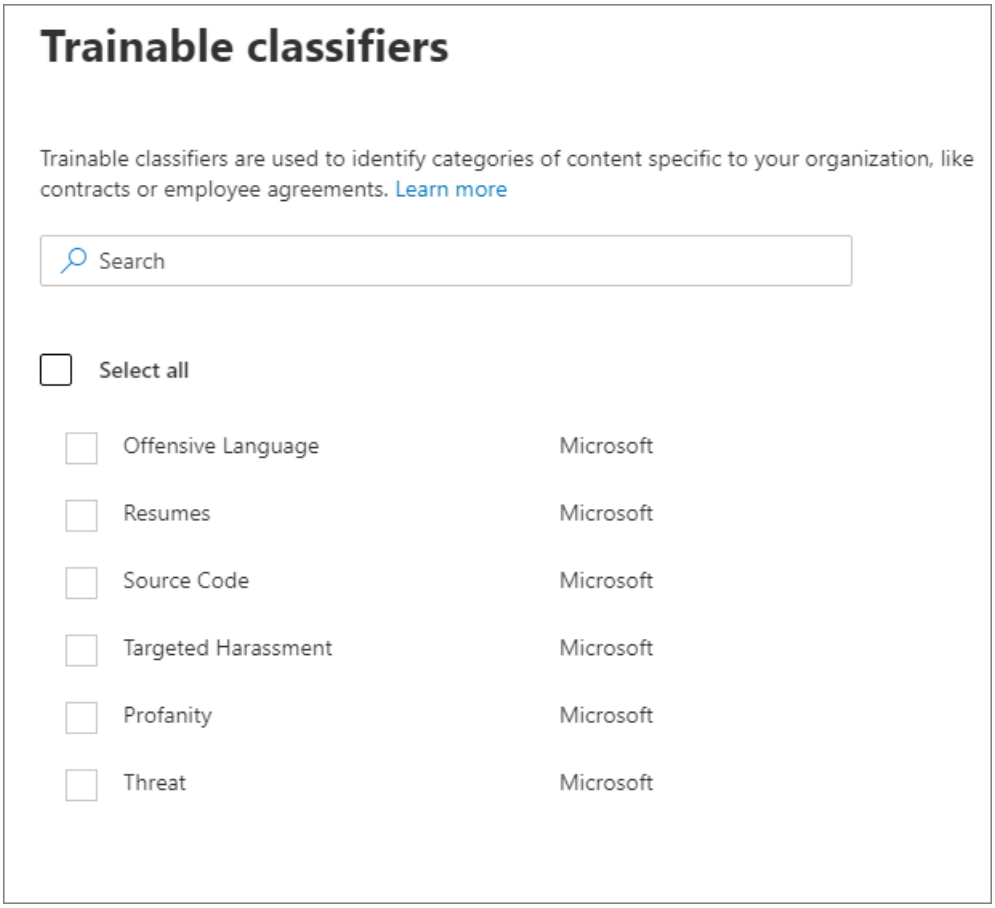
You can learn more about these configuration options from the DLP documentation: Tuning rules to make them easier or harder to match.

Also similarly to DLP policy configuration, you can choose whether a condition must detect all sensitive information types, or just one of them. And to make your conditions more flexible or complex, you can add groups and use logical operators between the groups.

Configuring trainable classifiers for a label

This option is currently in preview. If you use this option, make sure you have published in your tenant at least one other sensitivity label that's configured for auto-labeling and the sensitive info types option.

When you select the **Trainable classifiers** option, select one or more of the built-in trainable classifiers from Microsoft. If you've created your own custom trainable classifiers, these are also available to select:



Caution

We are deprecating the **Offensive Language** built-in classifier because it has been producing a high number of false positives. Don't use this built-in classifier and if you are currently using it, you should move your business processes off it. We recommend using the **Targeted Harassment**, **Profanity**, and **Threat** built-in classifiers instead.

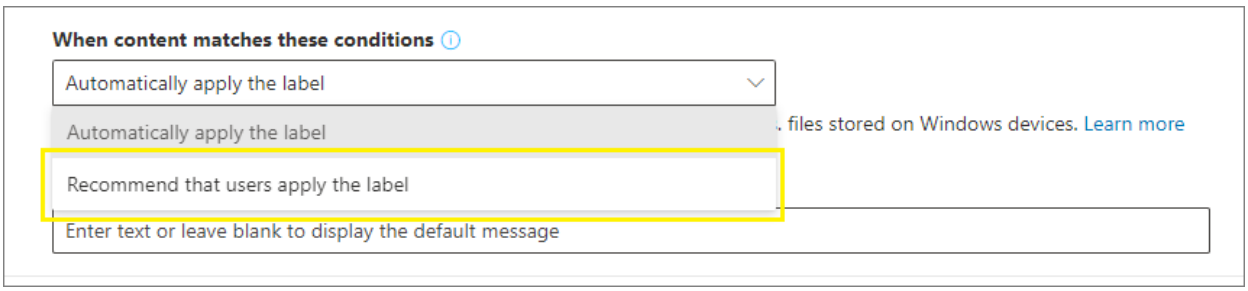
For more information about these classifiers, see Learn about trainable classifiers.

During the preview period for this option, the following apps support trainable classifiers for sensitivity labels:

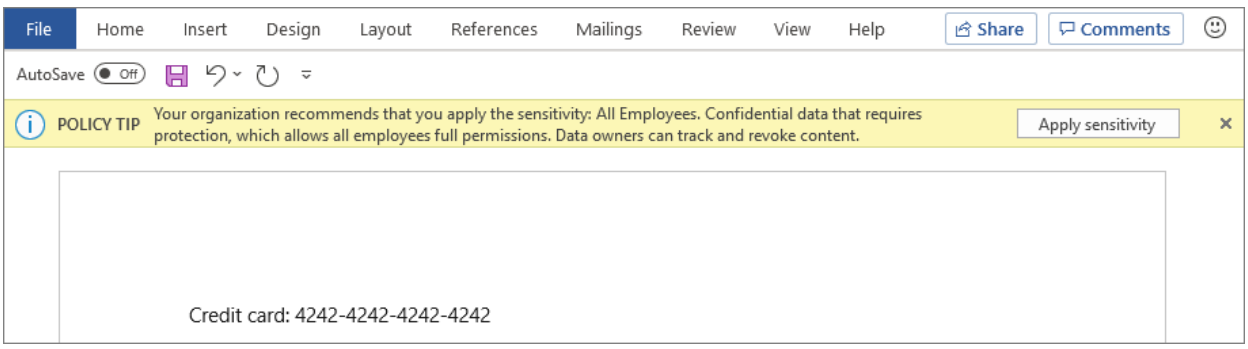
- Microsoft 365 Apps for enterprise (formerly Office 365 ProPlus) for Windows, now rolling out to the Current Channel in version 2006 and later:
  - Word
  - Excel
  - PowerPoint
- Office for the web apps, when you have enabled sensitivity labels for Office files in SharePoint and OneDrive:
  - Word
  - Excel
  - PowerPoint
  - Outlook

Recommend that the user applies a sensitivity label

If you prefer, you can recommend to your users that they apply the label. With this option, your users can accept the classification and any associated protection, or dismiss the recommendation if the label isn't suitable for their content.



Here's an example of a prompt from the Azure Information Protection unified labeling client when you configure a condition to apply a label as a recommended action, with a custom policy tip. You can choose what text is displayed in the policy tip.



When automatic or recommended labels are applied

The implementation of automatic and recommended labeling in Office apps depend on whether you're using labeling that's built into Office, or the Azure Information Protection unified labeling client. In both cases, however:

- You can't use automatic labeling for documents and emails that were previously manually labeled, or previously automatically labeled with a higher sensitivity. Remember, you can only apply a single sensitivity label to a document or email (in addition to a single retention label).
- You can't use recommended labeling for documents or emails that were previously labeled with a higher sensitivity. When the content's already labeled with a higher sensitivity, the user won't see the prompt with the recommendation and policy tip.

Specific to built-in labeling:

- Not all Office apps support automatic (and recommended) labeling. For more information, see Support for sensitivity label capabilities in apps.
- For recommended labels in the desktop versions of Word, the sensitive content that triggered the recommendation is flagged so that users can review and remove the sensitive content instead of applying the recommended sensitivity label.
- For details about how these labels are applied in Office apps, example screenshots, and how sensitive information is detected, see Automatically apply or recommend sensitivity labels to your files and emails in Office.

Specific to the Azure Information Protection unified labeling client:

- Automatic and recommended labeling applies to Word, Excel, and PowerPoint when you save a document, and to Outlook when you send an email.
- For Outlook to support recommended labeling, you must first configure an advanced policy setting.
- Sensitive information can be detected in the body text in documents and emails, and to headers and footers—but not in the subject line or attachments of email.

How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange

Make sure you're aware of the prerequisites before you configure auto-labeling policies.

Prerequisites for auto-labeling policies

- Simulation mode:
  - Auditing for Microsoft 365 must be turned on. If you need to turn on auditing or you're not sure whether auditing is already on, see Turn audit log search on or off.
  - To view file contents in the source view, you must have the **Content Explorer Content Viewer** role. Global admins don't have this role by default. If you don't have this permission, you don't see the preview pane when you select an item from the **Matched Items** tab.
- To auto-label files in SharePoint and OneDrive:
  - You have enabled sensitivity labels for Office files in SharePoint and OneDrive.
  - At the time the auto-labeling policy runs, the file mustn't be open by another process or user. A file that's checked out for editing falls into this category.
- If you plan to use custom sensitive information types rather than the built-in sensitivity types:
  - Custom sensitivity information types are evaluated for content that is added to SharePoint or OneDrive after the custom sensitivity information types are saved.
  - To test new custom sensitive information types, create them before you create your auto-labeling policy, and then create new documents with sample data for testing.
- One or more sensitivity labels created and published (to at least one user) that you can select for your

auto-labeling policies. For these labels:

- It doesn't matter if the auto-labeling in Office apps label setting is turned on or off, because that label setting supplements auto-labeling policies, as explained in the introduction.
- If the labels you want to use for auto-labeling are configured to use visual markings (headers, footers, watermarks), note that these are not applied to documents.
- If the labels apply encryption, they must be configured for the **Assign permissions now** setting.

Learn about simulation mode

Simulation mode is unique to auto-labeling policies and woven into the workflow. You can't automatically label documents and emails until your policy has run at least one simulation.

Workflow for an auto-labeling policy:

1. Create and configure an auto-labeling policy.
2. Run the policy in simulation mode, which can take 48 hours to complete.
3. Review the results, and if necessary, refine your policy. Rerun simulation mode and wait for it to complete again.
4. Repeat step 3 as needed.
5. Deploy in production.

The simulated deployment runs like the WhatIf parameter for PowerShell. You see results reported as if the auto-labeling policy had applied your selected label, using the rules that you defined. You can then refine your rules for accuracy if needed, and rerun the simulation. However, because auto-labeling for Exchange applies to emails that are sent and received, rather than emails stored in mailboxes, don't expect results for email in a simulation to be consistent unless you're able to send and receive the exact same email messages.

Simulation mode also lets you gradually increase the scope of your auto-labeling policy before deployment. For example, you might start with a single location, such as a SharePoint site, with a single document library. Then, with iterative changes, increase the scope to multiple sites, and then to another location, such as OneDrive.

Finally, you can use simulation mode to provide an approximation of the time needed to run your auto-labeling policy, to help you plan and schedule when to run it without simulation mode.

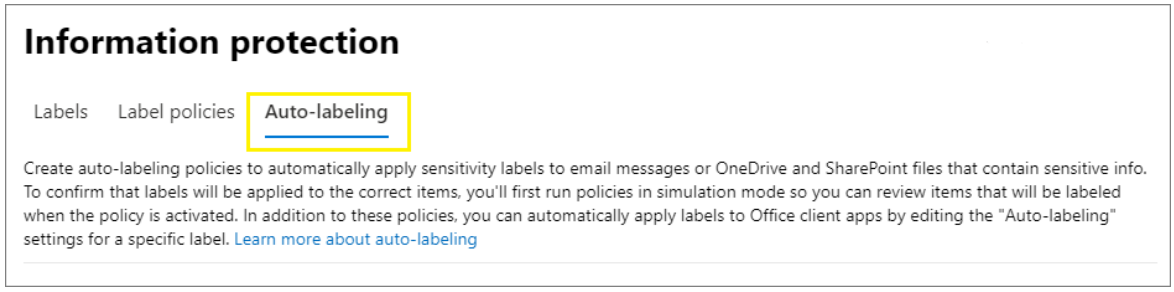
Creating an auto-labeling policy

1. In the Microsoft 365 compliance center, navigate to sensitivity labels:

   - **Solutions** > **Information protection**

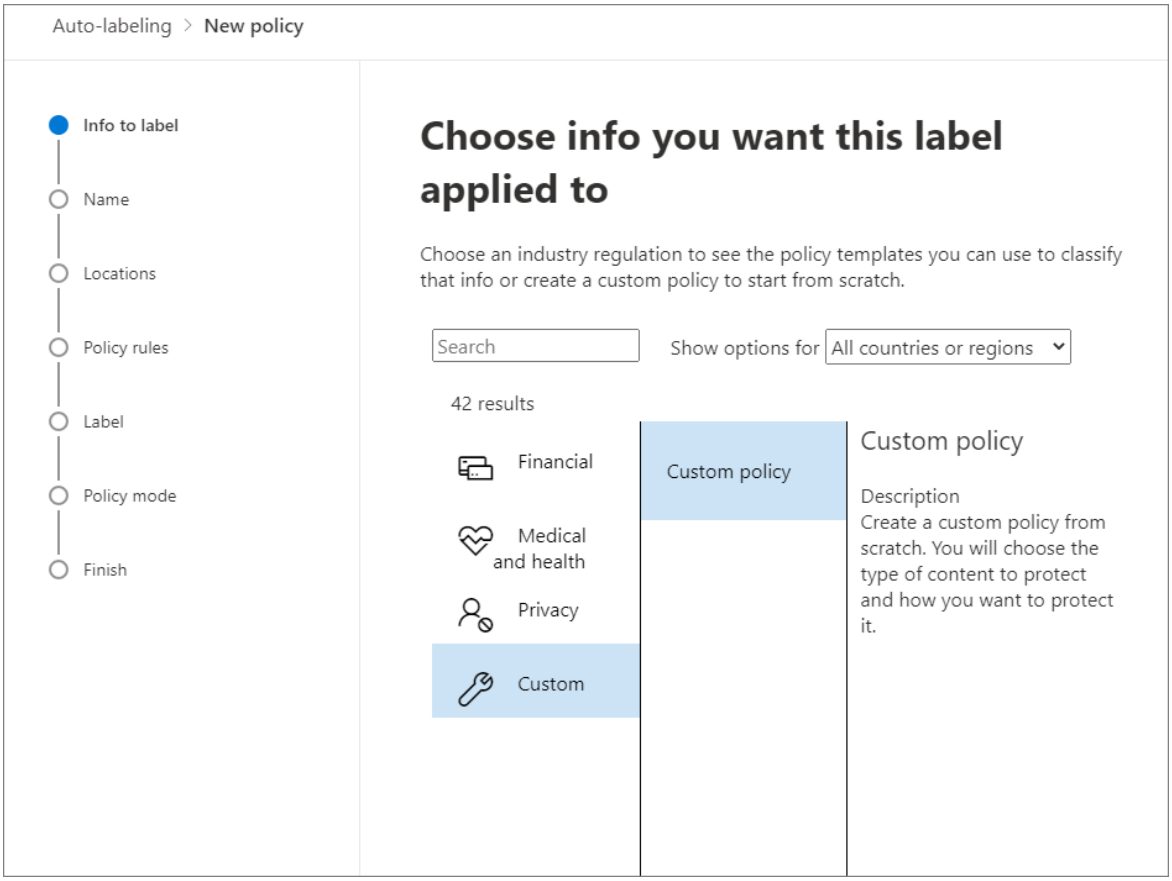
   If you don't immediately see this option, first select **Show all**.

2. Select the **Auto-labeling** tab:



> **NOTE**
>
> If you don't see the **Auto-labeling** tab, this functionality isn't currently available in your region.

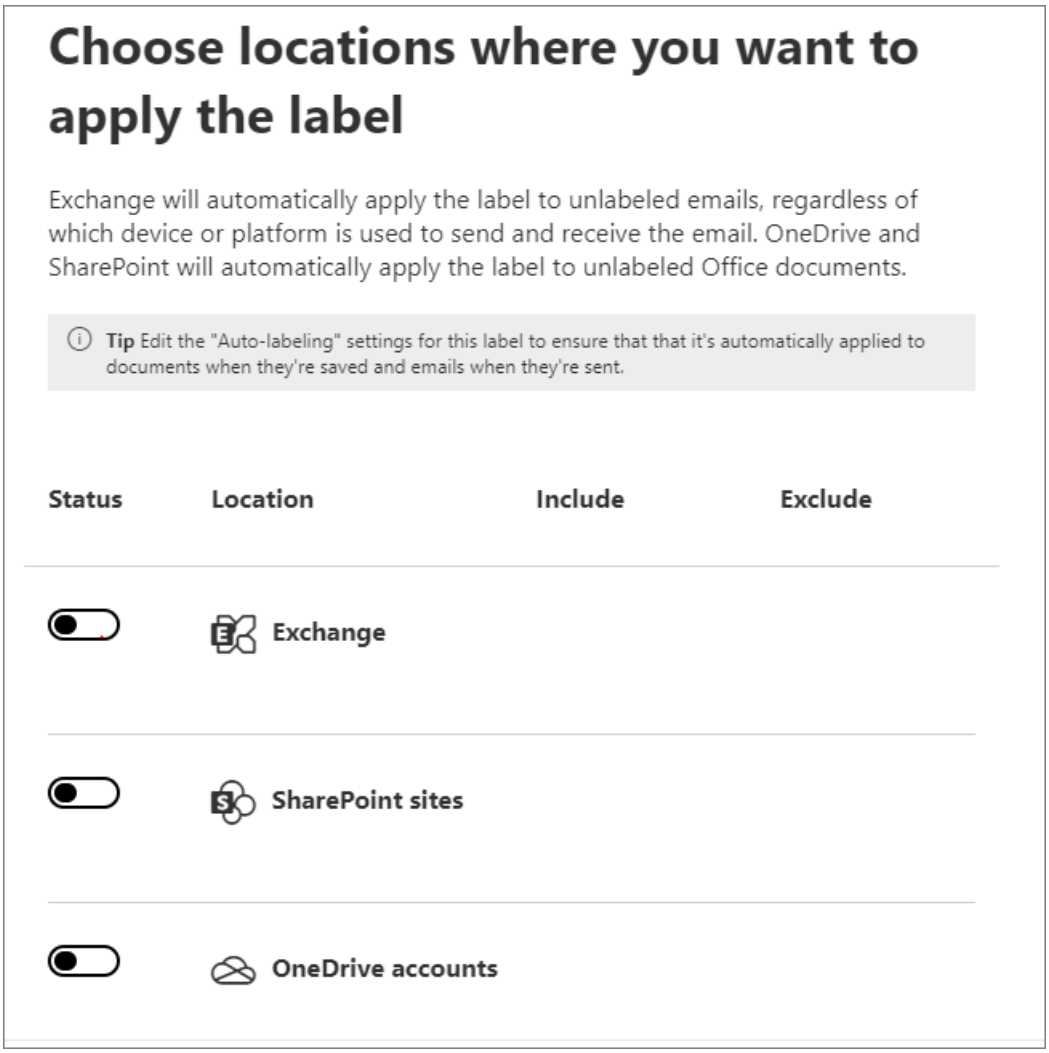
3. Select **+ Create auto-labeling policy**. This starts the New policy wizard:



4. For the page **Choose info you want this label applied to**: Select one of the templates, such as **Financial** or **Privacy**. You can refine your search by using the **Show options for** dropdown. Or, select **Custom policy** if the templates don't meet your requirements. Select **Next**.

5. For the page **Name your auto-labeling policy**: Provide a unique name, and optionally a description to help identify the automatically applied label, locations, and conditions that identify the content to label.

6. For the page **Choose locations where you want to apply the label**: Select and specify locations for Exchange, SharePoint sites, and OneDrive. Then select **Next**.



You must specify individual SharePoint sites and OneDrive accounts. For OneDrive, the URL for a user's OneDrive account is in the following format:

```
https://<tenant name>-my.sharepoint.com/personal/<user_name>_<tenant name>_com
```

For example, for a user in the contoso tenant that has a user name of "rsimone":

```
https://contoso-my.sharepoint.com/personal/rsimone_contoso_onmicrosoft_com
```

To verify the syntax for your tenant and identify URLs for users, see Get a list of all user OneDrive URLs in your organization.

7. For the **Set up common or advanced rules** page: Keep the default of **Common rules** to define rules that identify content to label across all your selected locations. If you need different rules per location, select **Advanced rules**. Then select **Next**.

   The rules use conditions that include sensitive information types and sharing options:

   - For sensitive information types, you can select both built-in and custom sensitive information types.
   - For the shared options, you can choose **only with people inside my organization** or **with people outside my organization**.

   If your only location is **Exchange**, or if you select **Advanced rules**, there are additional conditions that you can select:

   - Sender IP address is
   - Recipient domain is
   - Recipient is
   - Attachment's file extension is
   - Attachment is password protected

- Any email attachment's content could not be scanned
- Any email attachment's content didn't complete scanning

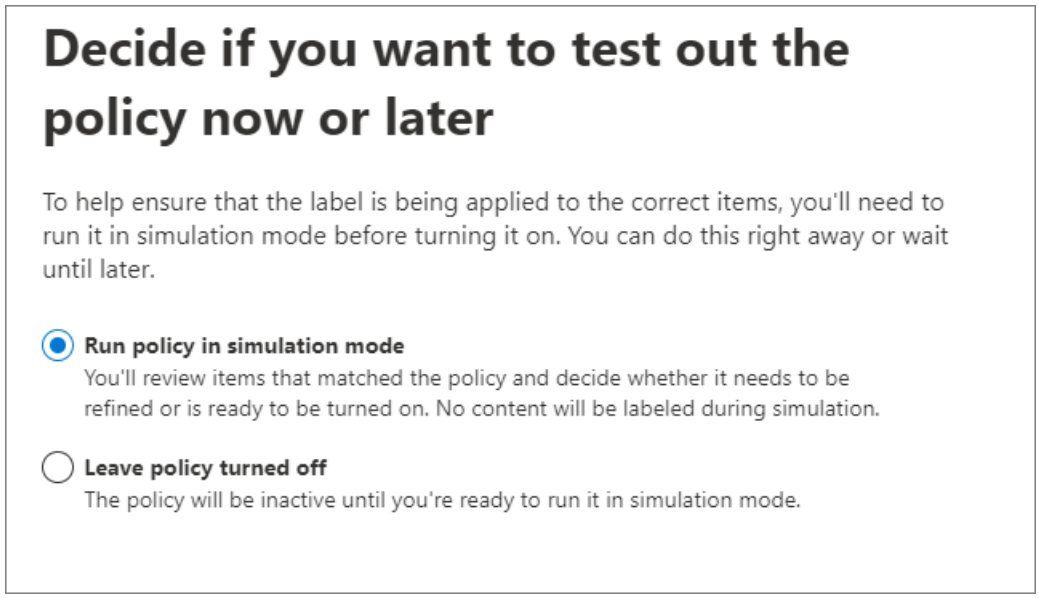
8. Depending on your previous choices, you'll now have an opportunity to create new rules by using conditions and exceptions.

   The configuration options for sensitive information types are the same as those you select for auto-labeling for Office apps. If you need more information, see Configuring sensitive info types for a label.

   When you have defined all the rules you need, and confirmed their status is on, select **Next** to move on to choosing a label to auto-apply.

9. For the **Choose a label to auto-apply** page: Select **+ Choose a label**, select a label from the **Choose a sensitivity label** pane, and then select **Next**.

10. For the **Decide if you want to test out the policy now or later** page: Select **Run policy in simulation mode** if you're ready to run the auto-labeling policy now, in simulation mode. Otherwise, select **Leave policy turned off**. Select **Next**:

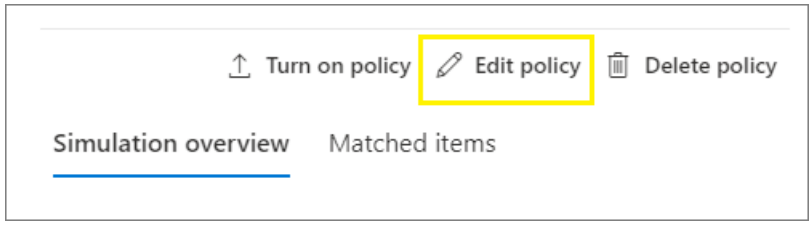


11. For the **Summary** page: Review the configuration of your auto-labeling policy and make any changes that needed, and complete the wizard.

Now on the **Information protection** > **Auto-labeling** page, you see your auto-labeling policy in the **Simulation** or **Off** section, depending on whether you chose to run it in simulation mode or not. Select your policy to see the details of the configuration and status (for example, **Policy simulation is still running**). For policies in simulation mode, select the **Matched items** tab to see which emails or documents matched the rules that you specified.

You can modify your policy directly from this interface:

- For a policy in the **Off** section, select the **Edit policy** button.
- For policy in the **Simulation** section, select the **Edit policy** option at the top of the page, from either tab:



When you're ready to run the policy without simulation, select the **Turn on policy** option.

Your auto-policies run continuously until they are deleted. For example, new and modified documents will be included with the current policy settings.

You can also see the results of your auto-labeling policy by using content explorer when you have the appropriate permissions:

- **Content Explorer List Viewer** lets you see a file's label but not the file's contents.
- **Content Explorer Content Viewer** lets you see the file's contents.

> **TIP**
> You can also use content explorer to identify locations that have documents with sensitive information, but are unlabeled. Using this information, consider adding these locations to your auto-labeling policy, and include the identified sensitive information types as rules.

Use PowerShell for auto-labeling policies

You can use Security & Compliance Center PowerShell to create and configure auto-labeling policies. This means you can fully script the creation and maintenance of your auto-labeling policies, which also provides a more efficient method of specifying multiple URLs for OneDrive and SharePoint locations.

Before you run the commands in PowerShell, you must first connect to Security & Compliance Center PowerShell.

To create a new auto-labeling policy:

```
New-AutoSensitivityLabelPolicy -Name <AutoLabelingPolicyName> -SharePointLocation "<SharePointSiteLocation>"
-ApplySensitivityLabel <Label> -Mode TestWithoutNotifications
```

This command creates an auto-labeling policy for a SharePoint site that you specify. For a OneDrive location, use the *OneDriveLocation* parameter, instead.

To add additional sites to an existing auto-labeling policy:

```
$spoLocations = @("<SharePointSiteLocation1>","<SharePointSiteLocation2>")
Set-AutoSensitivityLabelPolicy -Identity <AutoLabelingPolicyName> -AddSharePointLocation $spoLocations -
ApplySensitivityLabel <Label> -Mode TestWithoutNotifications
```

This command specifies the additional SharePoint URLs in a variable that is then added to an existing auto-labeling policy. To add OneDrive locations instead, use the *AddOneDriveLocation* parameter with a different variable, such as *$OneDriveLocations*.

To create a new auto-labeling policy rule:

```
New-AutoSensitivityLabelRule -Policy <AutoLabelingPolicyName> -Name <AutoLabelingRuleName> -
ContentContainsSensitiveInformation @{"name"= "a44669fe-0d48-453d-a9b1-2cc83f2cba77"; "mincount" = "2"} -
Workload SharePoint
```

For an existing auto-labeling policy, this command creates a new policy rule to detect the sensitive information type of **U.S. social security number (SSN)**, which has an entity ID of a44669fe-0d48-453d-a9b1-2cc83f2cba77. To find the entity IDs for other sensitive information types, refer to Sensitive information type entity definitions.

For more information about the PowerShell cmdlets that support auto-labeling policies, their available parameters and some examples, see the following cmdlet help:

- Get-AutoSensitivityLabelPolicy
- New-AutoSensitivityLabelPolicy
- New-AutoSensitivityLabelRule
- Remove-AutoSensitivityLabelPolicy
- Remove-AutoSensitivityLabelRule
- Set-AutoSensitivityLabelPolicy
- Set-AutoSensitivityLabelRule

Use sensitivity labels to protect content in Microsoft Teams, Microsoft 365 groups, and SharePoint sites

2/18/2021 • 17 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

In addition to using sensitivity labels to classify and protect documents and emails, you can also use sensitivity labels to protect content in the following containers: Microsoft Teams sites, Microsoft 365 groups (formerly Office 365 groups), and SharePoint sites. For this container-level classification and protection, use the following label settings:

- Privacy (public or private) of teams sites and Microsoft 365 groups
- External user access
- External sharing from SharePoint sites (in preview)
- Access from unmanaged devices

IMPORTANT

The **Access from unmanaged devices** setting works in conjunction with the SharePoint feature to control access from unmanaged devices. You must configure this dependent SharePoint feature to use a sensitivity label that has this setting configured. Additional information is included in the instructions that follow.

When you apply this sensitivity label to a supported container, the label automatically applies the classification and configured protection settings to the site or group.

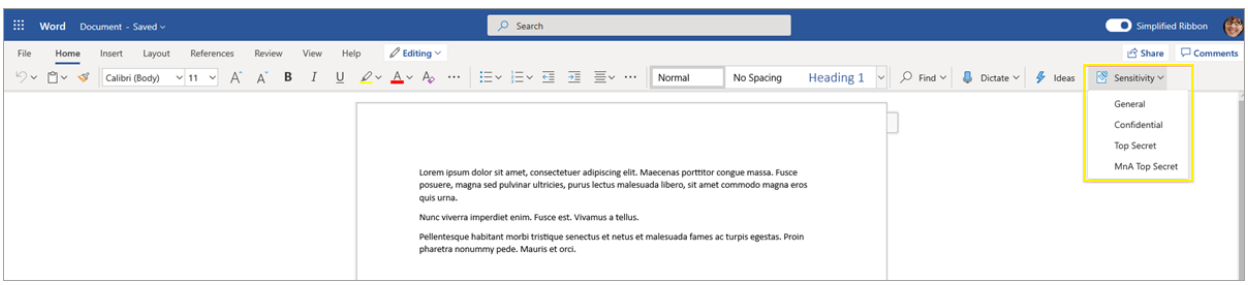
Content in these containers however, do not inherit the labels for the classification or settings for files and emails, such as visual markings and encryption. So that users can label their documents in SharePoint sites or team sites, make sure you've enabled sensitivity labels for Office files in SharePoint and OneDrive.

NOTE

Sensitivity labels for containers aren't supported with Office 365 Content Delivery Networks (CDNs).

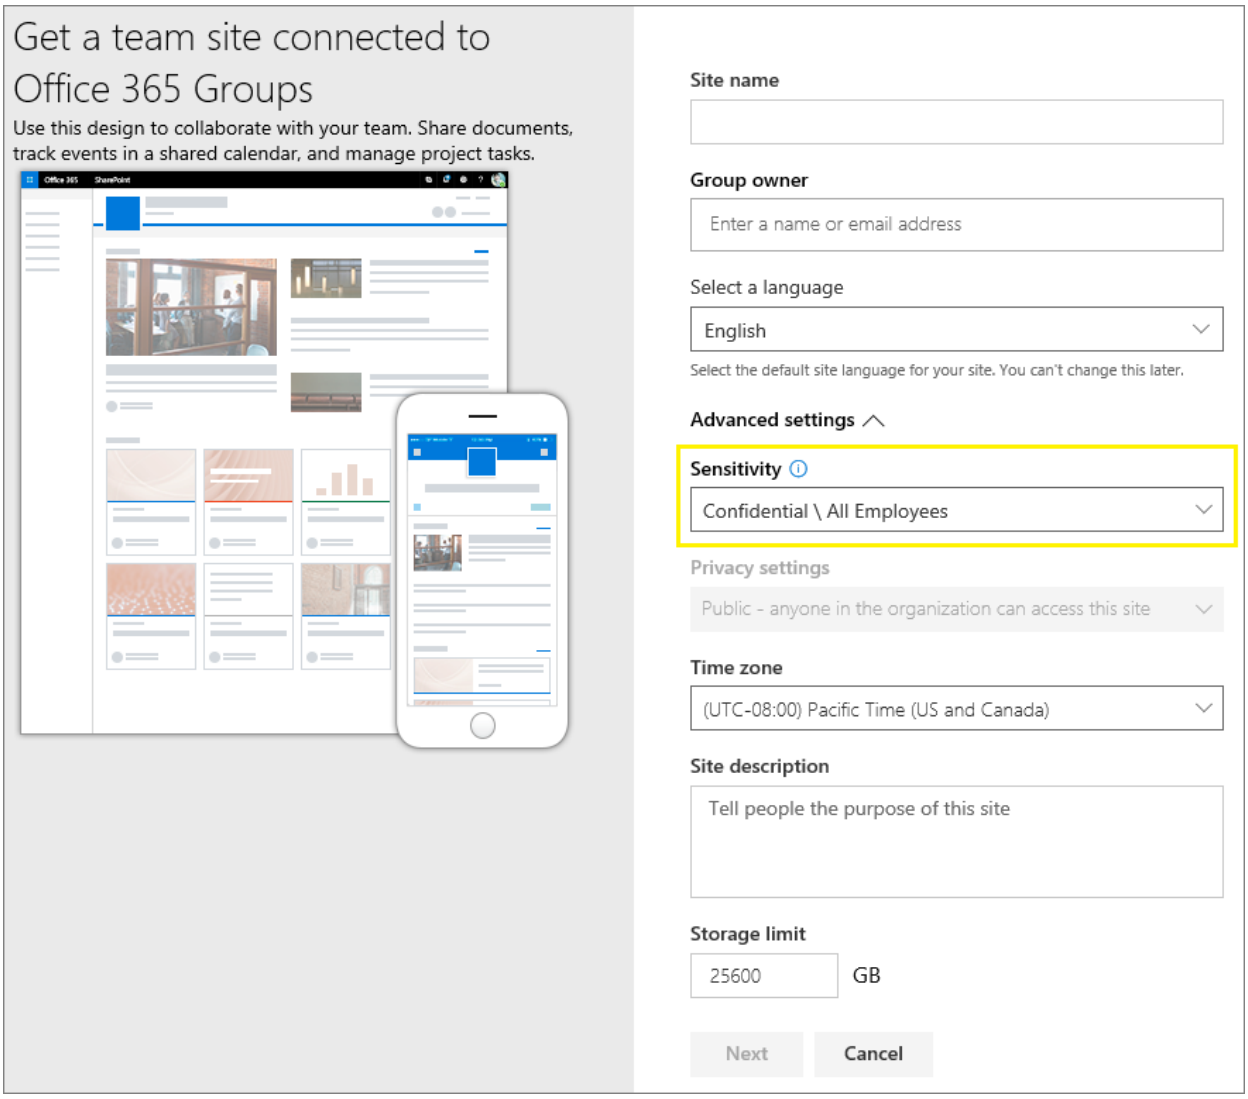
Using sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites

Before you enable sensitivity labels for containers and configure sensitivity labels for the new settings, users could see and apply sensitivity labels in their apps. For example, from Word:



After you enable and configure sensitivity labels for containers, users can additionally see and apply sensitivity

labels to Microsoft team sites, Microsoft 365 groups, and SharePoint sites. For example, when you create a new team site from SharePoint:



How to enable sensitivity labels for containers and synchronize labels

1. Because this feature uses Azure AD functionality, follow the instructions from the Azure AD documentation to enable sensitivity label support: Assign sensitivity labels to Microsoft 365 groups in Azure Active Directory.

2. You now need to synchronize your sensitivity labels to Azure AD. First, connect to Security & Compliance Center PowerShell.

   For example, in a PowerShell session that you run as administrator, sign in with a global administrator account.

3. Then run the following command to ensure your sensitivity labels can be used with Microsoft 365 groups:

   ```
   Execute-AzureAdLabelSync
   ```

How to configure groups and site settings

Enabling sensitivity labels for containers means that you can now configure protection settings for groups and sites in the sensitivity labeling wizard. Until you enable this support, the settings are visible in the wizard but you can't configure them.

1. Follow the general instructions to create or edit a sensitivity label and make sure you select **Groups & sites** for the label's scope:

   When only this scope is selected for the label, the label won't be displayed in Office apps that support sensitivity labels and can't be applied to files and emails. Having this separation of labels can be helpful for both users and administrators, but can also add to the complexity of your label deployment.

   For example, you need to carefully review your label ordering because SharePoint detects when a labeled document is uploaded to a labeled site. In this scenario, an audit event and email are automatically generated when the document has a higher priority sensitivity label than the site's label. For more information, see the Auditing sensitivity label activities section on this page.

2. Then, on the **Define protection settings for groups and sites** page, select one or both of the available options:

   - **Privacy and external user access settings** to configure the **Privacy** and **External users access** settings.
   - **Device access and external sharing settings** to configure the **Control external sharing from labeled SharePoint sites** and **Access from unmanaged devices** setting.

3. If you selected **Privacy and external user access settings**, now configure the following settings:

   - **Privacy**: Keep the default of **Public** if you want anyone in your organization to access the team site or group where this label is applied.

     Select **Private** if you want access to be restricted to only approved members in your organization.

     Select **None** when you want to protect content in the container by using the sensitivity label, but still let users configure the privacy setting themselves.

     The settings of **Public** or **Private** set and lock the privacy setting when you apply this label to the container. Your chosen setting replaces any previous privacy setting that might be configured for the team or group, and locks the privacy value so it can be changed only by first removing the sensitivity label from the container. After you remove the sensitivity label, the privacy setting from the label remains and users can now change it again.

   - **External user access**: Control whether the group owner can add guests to the group.

4. If you selected **Device access and external sharing setting**, now configure the following settings:

   - **Control external sharing from labeled SharePoint sites**: Currently in preview, select this option to then select either external sharing for anyone, new and existing guests, existing guests,

or only people in your organization. For more information about this configuration and settings, see the SharePoint documentation, Turn external sharing on or off for a site.

- **Access from unmanaged devices**: This option uses the SharePoint feature that uses Azure AD conditional access to block or limit access to SharePoint and OneDrive content from unmanaged devices. For more information, see Control access from unmanaged devices from the SharePoint documentation. The option you specify for this label setting is the equivalent of running a PowerShell command for a site, as described in steps 3-5 from the Block or limit access to a specific SharePoint site or OneDrive section from the SharePoint instructions.

  For additional information, see More information about the dependencies for the unmanaged devices option at the end of this section.

> **IMPORTANT**
>
> Only these site and group settings take effect when you apply the label to a team, group, or site. If the label's scope includes files and emails, other label settings such as encryption and content marking aren't applied to the content within the team, group, or site.

If your sensitivity label isn't already published, now publish it by adding it to a sensitivity label policy. The users who are assigned a sensitivity label policy that includes this label will be able to select it for sites and groups.

More information about the dependencies for the unmanaged devices option

If you don't configure the dependent conditional access policy for SharePoint as documented in Use app-enforced restrictions, the option you specify here will have no effect. Additionally, it will have no effect if it's less restrictive than a configured setting at the tenant level. If you have configured an organization-wide setting for unmanaged devices, choose a label setting that's either the same or more restrictive

For example, if your tenant is configured for **Allow limited, web-only access**, the label setting that allows full access will have no effect because it's less restrictive. For this tenant-level setting, choose the label setting to block access (more restrictive) or the label setting for limited access (the same as the tenant setting).

Because you can configure the SharePoint settings separately from the label configuration, there's no check in the sensitivity label wizard that the dependencies are in place. These dependencies can be configured after the label is created and published, and even after the label is applied. However, if the label is already applied, the label setting won't take effect until after the user next authenticates.

Sensitivity label management

Use the following guidance for when you create, modify, or delete sensitivity labels that are configured for sites and groups.

Creating and publishing labels that are configured for sites and groups

When a new sensitivity label is created and published, it's visible for users in teams, groups, and sites within one hour. However, if you modify an existing label, allow up to 24 hours. Use the following guidance to publish a label for your users when that label is configured for site and group settings:

1. After you create and configure the sensitivity label, add this label to a label policy that applies to just a few test users.
2. Wait for the change to replicate:
   - New label: Wait for one hour.
   - Existing label: Wait for 24 hours.
3. After this wait period, use one of the test user accounts to create a team, Microsoft 365 group, or SharePoint site with the label that you created in step 1.

4. If there are no errors during this creation operation, you know it's safe to publish the label to all users in your tenant.

Modifying published labels that are configured for sites and groups

As a best practice, don't change the site and group settings for a sensitivity label after the label has been applied to teams, groups, or sites. If you do, remember to wait for 24 hours for the changes to replicate to all containers that have the label applied.

In addition, if your changes include the **External users access** setting:

- The new setting applies to new users but not to existing users. For example, if this setting was previously selected and as a result, guest users accessed the site, these guest users can still access the site after this setting is cleared in the label configuration.
- The privacy settings for the group properties hiddenMembership and roleEnabled aren't updated.

Deleting published labels that are configured for sites and groups

If you delete a sensitivity label that has the site and group settings enabled, and that label is included in one or more label policies, this action can result in creation failures for new teams, groups, and sites. To avoid this situation, use the following guidance:

1. Remove the sensitivity label from all label policies that include the label.
2. Wait for one hour.
3. After this wait period, try creating a team, group, or site and confirm that the label is no longer visible.
4. If the sensitivity label isn't visible, you can now safely delete the label.

How to apply sensitivity labels to containers

You're now ready to apply the sensitivity label or labels to the following containers:

- Microsoft 365 group in Azure AD
- Microsoft Teams team site
- Microsoft 365 group in Outlook on the web
- SharePoint site

You can use PowerShell if you need to apply a sensitivity label to multiple sites.

Apply sensitivity labels to Microsoft 365 groups

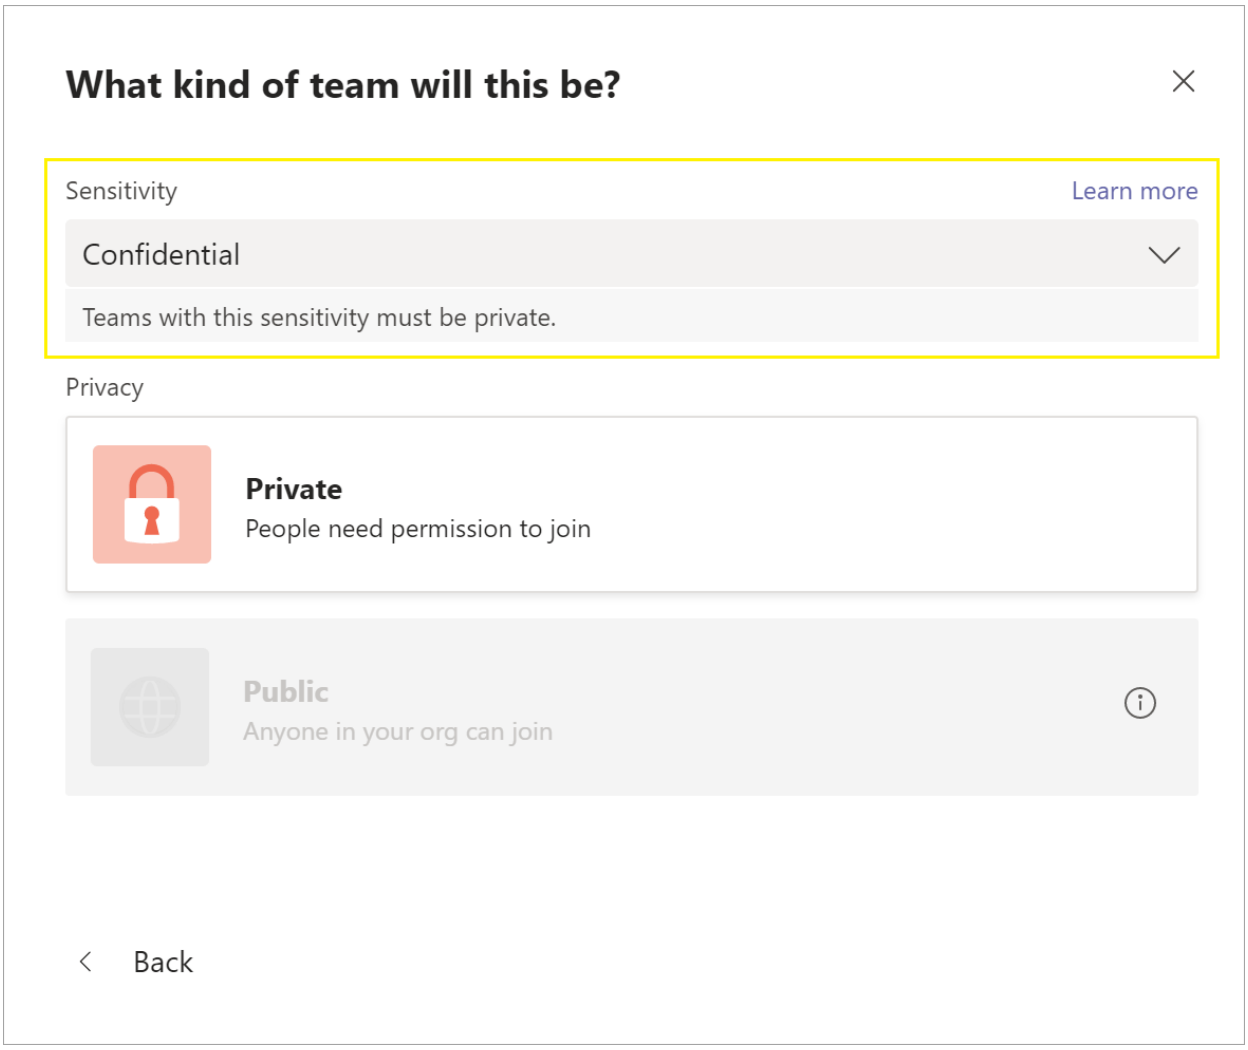
You're now ready to apply the sensitivity label or labels to Microsoft 365 groups. Return to the Azure AD documentation for instructions:

- Assign a label to a new group in Azure portal
- Assign a label to an existing group in Azure portal
- Remove a label from an existing group in Azure portal.

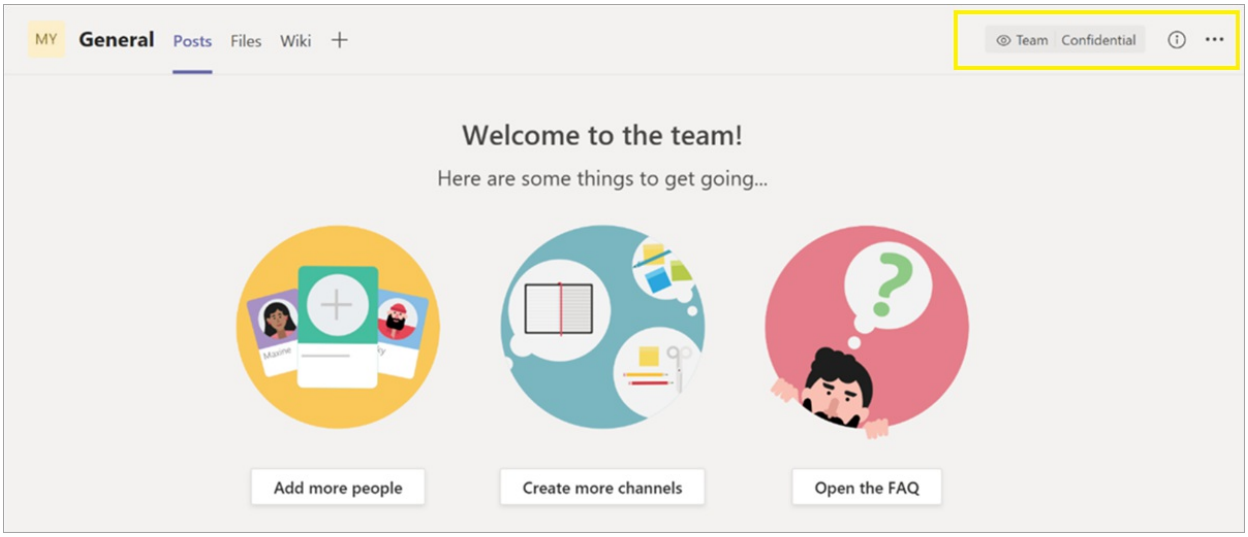
Apply a sensitivity label to a new team

Users can select sensitivity labels when they create new teams in Microsoft Teams. When they select the label from the **Sensitivity** dropdown, the privacy setting might change to reflect the label configuration. Depending on the external users access setting you selected for the label, users can or can't add people outside the organization to the team.

Learn more about sensitivity labels for Teams



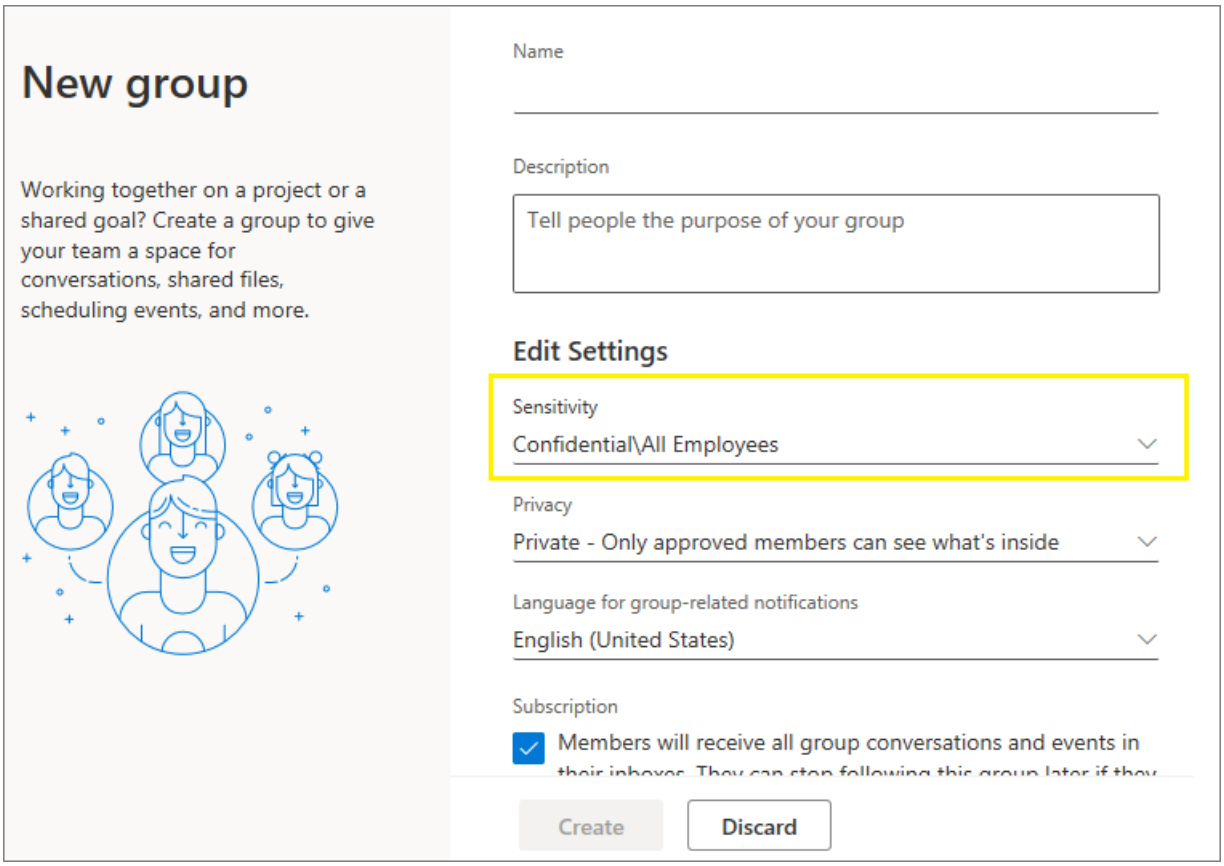
After you create the team, the sensitivity label appears in the upper-right corner of all channels.



The service automatically applies the same sensitivity label to the Microsoft 365 group and the connected SharePoint team site.

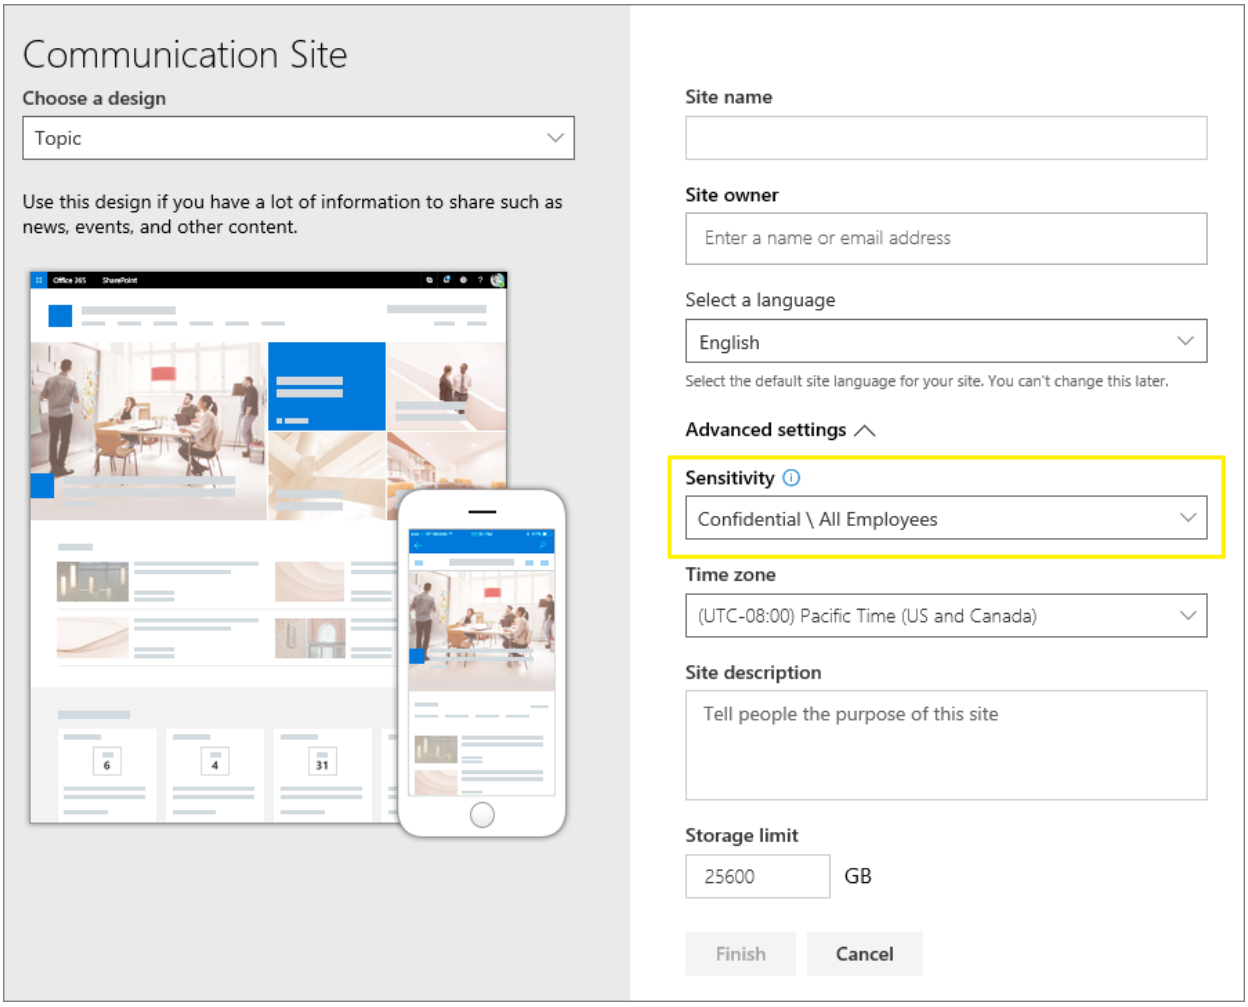
Apply a sensitivity label to a new group in Outlook on the web

In Outlook on the web, when you create a new group, you can select or change the **Sensitivity** option for published labels:



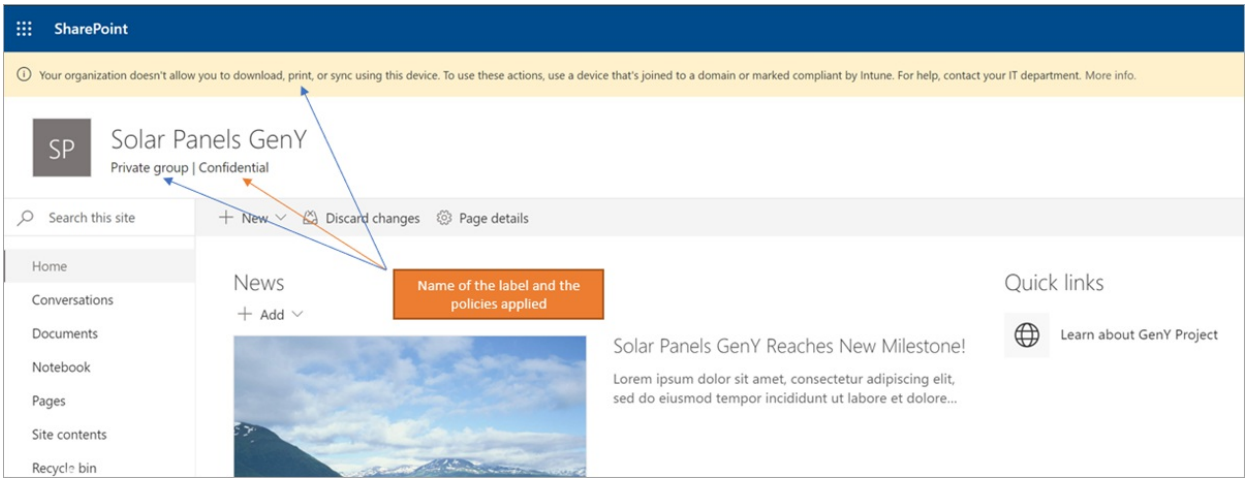
Apply a sensitivity label to a new site

Admins and end users can select sensitivity labels when they create modern team sites and communication sites, and expand **Advanced settings**:



The dropdown box displays the label names for the selection, and the help icon displays all the label names with their tooltip, which can help users determine the correct label to apply.

When the label is applied, and users browse to the site, they see the name of the label and applied policies. For example, this site has been labeled as **Confidential**, and the privacy setting is set to **Private**:



Use PowerShell to apply a sensitivity label to multiple sites

You can use the Set-SPOSite and Set-SPOTenant cmdlet with the *SensitivityLabel* parameter from the current SharePoint Online Management Shell to apply a sensitivity label to many sites. The sites can be any SharePoint site collection, or a OneDrive site.

Make sure you have version 16.0.19418.12000 or later of the SharePoint Online Management Shell.

1. Open a PowerShell session with the **Run as Administrator** option.
2. If you don't know your label GUID: Connect to Security & Compliance Center PowerShell and get the list of sensitivity labels and their GUIDs.

   ```
   Get-Label |ft Name, Guid
   ```

3. Now connect to SharePoint Online PowerShell and store your label GUID as a variable. For example:

   ```
   $Id = [GUID]("e48058ea-98e8-4940-8db0-ba1310fd955e")
   ```

4. Create a new variable that identifies multiple sites that have an identifying string in common in their URL. For example:

   ```
   $sites = Get-SPOSite -IncludePersonalSite $true -Limit all -Filter "Url -like 'documents"
   ```

5. Run the following command to apply the label to these sites. Using our examples:

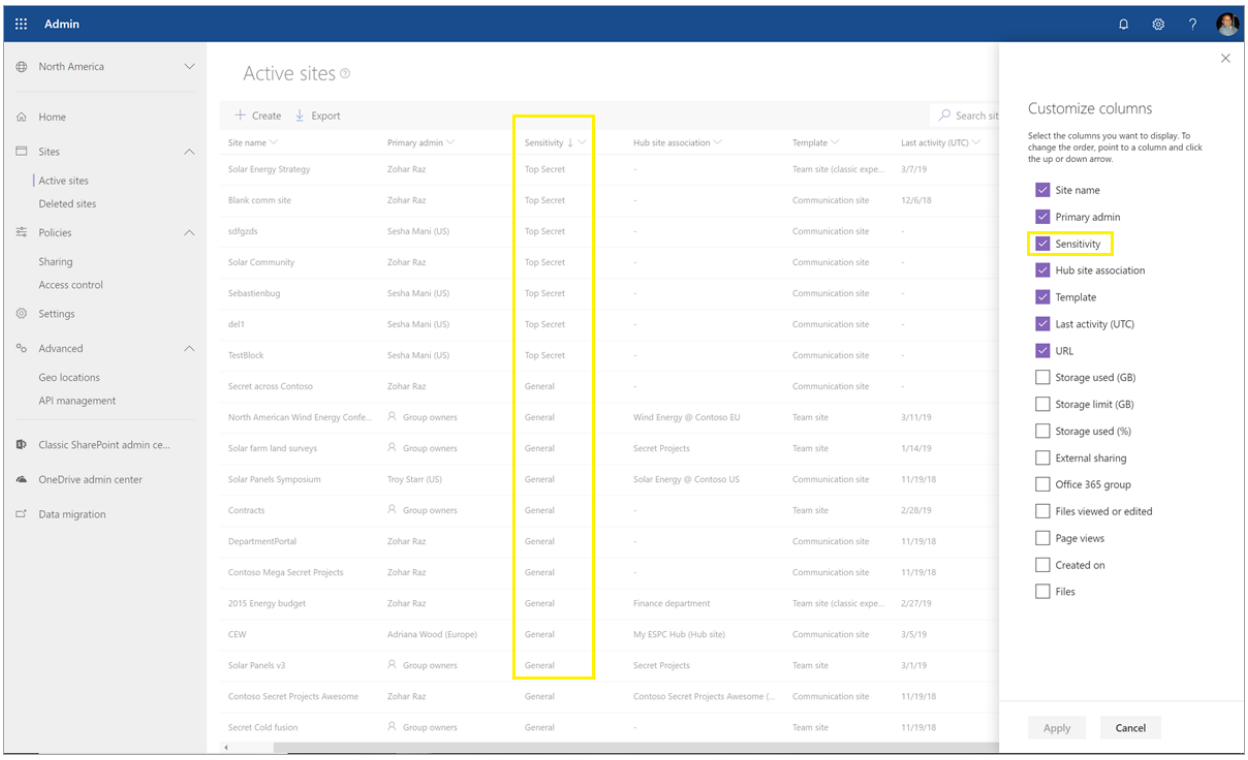
   ```
   $sites | ForEach-Object {Set-SPOTenant $_.url -SensitivityLabel $Id}
   ```

To apply different labels to different sites, repeat the following command for each site:

```
Set-SPOSite -Identity <URL> -SensitivityLabel "<labelguid>"
```

View and manage sensitivity labels in the SharePoint admin center

To view, sort, and search the applied sensitivity labels, use the **Active sites** page in the new SharePoint admin center. You might need to first add the **Sensitivity** column:



For more information about managing sites from the Active sites page, including how to add a column, see Manage sites in the new SharePoint admin center.

You can also change and apply a label from this page:

1. Select the site name to open the details pane.
2. Select the **Policies** tab, and then select **Edit** for the **Sensitivity** setting.
3. From the **Edit sensitivity setting** pane, select the sensitivity label you want to apply to the site, and then select **Save**.

Support for sensitivity labels

The following apps and services support sensitivity labels configured for sites and group settings:

- Admin centers:
  - SharePoint admin center
  - Azure Active Directory portal
  - Microsoft 365 admin center
  - Microsoft 365 compliance center, Microsoft 365 security center, Security & Compliance Center
- User apps and services:
  - SharePoint
  - Teams
  - Outlook on the web and for Windows, macOS, iOS, and Android
  - Forms
  - Stream
  - Planner

The following apps and services don't currently support sensitivity labels configured for sites and group settings:

- Admin centers:

    - Teams admin center
    - Exchange admin center
- User apps and services:
    - Dynamics 365
    - Yammer
    - Project

Classic Azure AD group classification

Microsoft 365 no longer supports the old classifications for new Microsoft 365 groups and SharePoint sites after you enable sensitivity labels for containers. However, existing groups and sites that support sensitivity labels still display the old classification values until you convert them to use sensitivity labels.

As an example of how you might have used the old group classification for SharePoint, see SharePoint "modern" sites classification.

These classifications were configured by using Azure AD PowerShell or the PnP Core library and defining values for the `ClassificationList` setting. If your tenant has classification values defined, they are shown when you run the following command from the AzureADPreview PowerShell module:

```
($setting["ClassificationList"])
```

To convert your old classifications to sensitivity labels, do one of the following:

- Use existing labels: Specify the label settings you want for sites and groups by editing existing sensitivity labels that are already published.
- Create new labels: Specify the label settings you want for sites and groups by creating and publishing new sensitivity labels that have the same names as your existing classifications.

Then:

1. Use PowerShell to apply the sensitivity labels to existing Microsoft 365 groups and SharePoint sites by using name mapping. See the next section for instructions.
2. Remove the old classifications from the existing groups and sites.

Although you can't prevent users from creating new groups in apps and services that don't yet support sensitivity labels, you can run a recurring PowerShell script to look for new groups that users have created with the old classifications, and convert these to use sensitivity labels.

To help you manage the coexistence of sensitivity labels and Azure AD classifications for sites and groups, see Azure Active Directory classification and sensitivity labels for Microsoft 365 groups.

Use PowerShell to convert classifications for Microsoft 365 groups to sensitivity labels

1. First, connect to Security & Compliance Center PowerShell.

   For example, in a PowerShell session that you run as administrator, sign in with a global administrator account:

2. Get the list of sensitivity labels and their GUIDs by using the Get-Label cmdlet:

   ```
   Get-Label |ft Name, Guid
   ```

3. Make a note of the GUIDs for the sensitivity labels you want to apply to your Microsoft 365 groups.
4. Now connect to Exchange Online PowerShell in a separate Windows PowerShell window.
5. Use the following command as an example to get the list of groups that currently have the classification of "General":

```
$Groups= Get-UnifiedGroup | Where {$_.classification -eq "General"}
```

6. For each group, add the new sensitivity label GUID. For example:

```
foreach ($g in $groups)
{Set-UnifiedGroup -Identity $g.Identity -SensitivityLabelId "457fa763-7c59-461c-b402-ad1ac6b703cc"}
```

7. Repeat steps 5 and 6 for your remaining group classifications.

Auditing sensitivity label activities

> **IMPORTANT**
> If you use label separation by selecting just the **Groups & sites** scope for labels that protect containers: Because of the **Detected document sensitivity mismatch** audit event and email described in this section, consider ordering these labels before labels that have a scope for **Files & emails**.

If somebody uploads a document to a site that's protected with a sensitivity label and their document has a higher priority sensitivity label than the sensitivity label applied to the site, this action isn't blocked. For example, you've applied the **General** label to a SharePoint site, and somebody uploads to this site a document labeled **Confidential**. Because a sensitivity label with a higher priority identifies content that is more sensitivity than content that has a lower priority order, this situation could be a security concern.

Although the action isn't blocked, it is audited and automatically generates an email to the person who uploaded the document and the site administrator. As a result, both the user and administrators can identify documents that have this misalignment of label priority and take action if needed. For example, delete or move the uploaded document from the site.

It wouldn't be a security concern if the document has a lower priority sensitivity label than the sensitivity label applied to the site. For example, a document labeled **General** is uploaded to a site labeled **Confidential**. In this scenario, an auditing event and email aren't generated.

To search the audit log for this event, look for **Detected document sensitivity mismatch** from the **File and page activities** category.

The automatically generated email has the subject **Incompatible sensitivity label detected** and the email message explains the labeling mismatch with a link to the uploaded document and site. It also contains a documentation link that explains how users can change the sensitivity label. Currently, these automated emails cannot be disabled or customized.

When somebody adds or removes a sensitivity label to or from a site or group, these activities are also audited but without automatically generating an email.

All these auditing events can be found in the Sensitivity label activities category. For instructions to search the audit log, see Search the audit log in the Security & Compliance Center.

How to disable sensitivity labels for containers

You can turn off sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites by using the same instructions from Enable sensitivity label support in PowerShell. However, to disable the feature, in step 5, specify `$setting["EnableMIPLabels"] = "False"`.

In addition to making all the settings unavailable for groups and sites when you create or edit sensitivity labels, this action reverts which property the containers use for their configuration. Enabling sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites switches the property used from **Classification** (used for Azure AD group classification) to **Sensitivity**. When you disable sensitivity labels for containers, the containers ignore the Sensitivity property and use the Classification property again.

This means that any label settings from sites and groups previously applied to containers won't be enforced, and containers no longer display the labels.

If these containers have Azure AD classification values applied to them, the containers revert to using the classifications again. Be aware that any new sites or groups that were created after enabling the feature won't display a label or have a classification. For these containers, and any new containers, you can now apply classification values. For more information, see SharePoint "modern" sites classification and Create classifications for Office groups in your organization.

Additional resources

See the webinar recording and answered questions for Using Sensitivity labels with Microsoft Teams, O365 Groups and SharePoint Online sites.

This webinar was recorded when the feature was still in preview, so you might notice some discrepancies in the UI. However, the information for this feature is still accurate, with any new capabilities documented on this page.

Enable sensitivity labels for Office files in SharePoint and OneDrive

2/18/2021 • 15 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

Enable sensitivity labels for Office files in SharePoint and OneDrive so that users can apply your sensitivity labels in Office on the web. When this feature is enabled, users will see the **Sensitivity** button on the ribbon so they can apply labels, and see any applied label name on the status bar.

Enabling this feature also results in SharePoint and OneDrive being able to process the contents of files that have been encrypted by using a sensitivity label. The label can be applied in Office for the web, or in Office desktop apps and uploaded or saved in SharePoint and OneDrive. Until you enable this feature, these services can't process encrypted files, which means that coauthoring, eDiscovery, Data Loss Prevention, search, and other collaborative features won't work for these files.

After you enable sensitivity labels for Office files in SharePoint and OneDrive, for new and changed files that have a sensitivity label that applies encryption with a cloud-based key (and doesn't use Double Key Encryption):

- For Word, Excel, and PowerPoint files, SharePoint and OneDrive recognize the label and can now process the contents of the encrypted file.
- When users download or access these files from SharePoint or OneDrive, the sensitivity label and any encryption settings from the label are enforced and remain with the file, wherever it is stored. Ensure you provide user guidance to use only labels to protect documents. For more information, see Information Rights Management (IRM) options and sensitivity labels.
- When users upload labeled and encrypted files to SharePoint or OneDrive, they must have at least view rights to those files. For example, they can open the files outside SharePoint. If they don't have this minimum usage right, the upload is successful but the service doesn't recognize the label and can't process the file contents.
- Use Office on the web (Word, Excel, PowerPoint) to open and edit Office files that have sensitivity labels that apply encryption. The permissions that were assigned with the encryption are enforced. You can also use auto-labeling for these documents.
- External users can access documents that are labeled with encryption by using guest accounts. For more information, see Support for external users and labeled content.
- Office 365 eDiscovery supports full-text search for these files and Data Loss Prevention (DLP) policies support content in these files.

NOTE

If encryption has been applied with an on-premises key (a key management topology often referred to as "hold your own key" or HYOK), or by using Double Key Encryption, the service behavior for processing the file contents doesn't change. So for these files, coauthoring, eDiscovery, Data Loss Prevention, search, and other collaborative features won't work.

The SharePoint and OneDrive behavior also doesn't change for existing files in these locations that are labeled with encryption using a single Azure-based key. For these files to benefit from the new capabilities after you enable sensitivity labels for Office files in SharePoint and OneDrive, the files must be either downloaded and uploaded again, or edited.

After you enable sensitivity labels for Office files in SharePoint and OneDrive, three new audit events are available for monitoring sensitivity labels that are applied to documents in SharePoint and OneDrive:

- **Applied sensitivity label to file**
- **Changed sensitivity label applied to file**
- **Removed sensitivity label from file**

Watch the following video (no audio) to see the new capabilities in action:

You always have the choice to disable sensitivity labels for Office files in SharePoint and OneDrive (opt-out) at any time.

If you are currently protecting documents in SharePoint by using SharePoint Information Rights Management (IRM), be sure to check the SharePoint Information Rights Management (IRM) and sensitivity labels section on this page.

Requirements

These new capabilities work with sensitivity labels only. If you currently have Azure Information Protection labels, first migrate them to sensitivity labels so that you can enable these features for new files that you upload. For instructions, see How to migrate Azure Information Protection labels to unified sensitivity labels.

Use the OneDrive sync app version 19.002.0121.0008 or later on Windows, and version 19.002.0107.0008 or later on Mac. Both these versions were released January 28, 2019, and are currently released to all rings. For more information, see the OneDrive release notes. After you enable sensitivity labels for Office files in SharePoint and OneDrive, users who run an older version of the sync app are prompted to update it.

Limitations

- SharePoint and OneDrive don't automatically apply sensitivity labels to existing files that you've already encrypted using Azure Information Protection labels. Instead, for the features to work after you enable sensitivity labels for Office files in SharePoint and OneDrive, complete these tasks:

  1. Make sure you have migrated the Azure Information Protection labels to sensitivity labels and published them from the Microsoft 365 compliance center, or equivalent labeling admin center.
  2. Download the files and then upload them to SharePoint.

- SharePoint and OneDrive can't process encrypted files when the label that applied the encryption has any of the following configurations for encryption:

  - **Let users assign permissions when they apply the label** and the checkbox **In Word, PowerPoint, and Excel, prompt users to specify permissions** is selected. This setting is sometimes referred to as "user-defined permissions".
  - **User access to content expires** is set to a value other than **Never**.
  - **Double Key Encryption** is selected.

  For labels with any of these encryption configurations, the labels aren't displayed to users in Office on the web. Additionally, the new capabilities can't be used with labeled documents that already have these encryption settings. For example, these documents won't be returned in search results, even if they are updated.

- For encrypted documents, printing is not supported.

- For an encrypted document that grants edit permissions to a user, copying can't be blocked in the web versions of the Office apps.

- The Azure Information Protection document tracking site is not supported.
- Office desktop apps and mobile apps don't support coauthoring for files that are labeled with encryption. These apps continue to open labeled and encrypted files in exclusive editing mode.
- If an admin changes settings for a published label that's already applied to files downloaded to users' sync client, users might be unable to save changes they make to the file in their OneDrive Sync folder. This scenario applies to files that are labeled with encryption, and also when the label change is from a label that didn't apply encryption to a label that does apply encryption. Users see a red circle with a white cross icon error, and they are asked to save new changes as a separate copy. Instead, they can close and reopen the file, or use Office on the web.
- If a labeled document is uploaded to SharePoint or OneDrive and the label applied encryption by using an account from a service principal name, the document can't be opened in Office on the web. Example scenarios include Microsoft Cloud App Security and a file sent to Teams by email.
- Users can experience save problems after going offline or into a sleep mode when instead of using Office for the web, they use the desktop and mobile apps for Word, Excel, or PowerPoint. For these users, when they resume their Office app session and try to save changes, they see an upload failure message with an option to save a copy instead of saving the original file.
- Documents that have been encrypted in the following ways can't be opened in Office on the web:
  - Encryption that uses an on-premises key ("hold your own key" or HYOK)
  - Encryption that was applied by using Double Key Encryption
  - Encryption that was applied independently from a label, for example, by directly applying a Rights Management protection template.
- Labels configured for other languages are not supported and display the original language only.
- Screen captures can't be prevented for encrypted documents. For more information, see Can Rights Management prevent screen captures?
- If you delete a label that's been applied to a document in SharePoint or OneDrive, rather than remove the label from the applicable label policy, the document when downloaded won't be labeled or encrypted. In comparison, if the labeled document is stored outside SharePoint or OneDrive, the document remains encrypted if the label is deleted. Note that although you might delete labels during a testing phase, it's very rare to delete a label in a production environment.

How to enable sensitivity labels for SharePoint and OneDrive (opt-in)

You can enable the new capabilities by using the Microsoft 365 compliance center, or by using PowerShell. As with all tenant-level configuration changes for SharePoint and OneDrive, it takes about 15 minutes for the change to take effect.

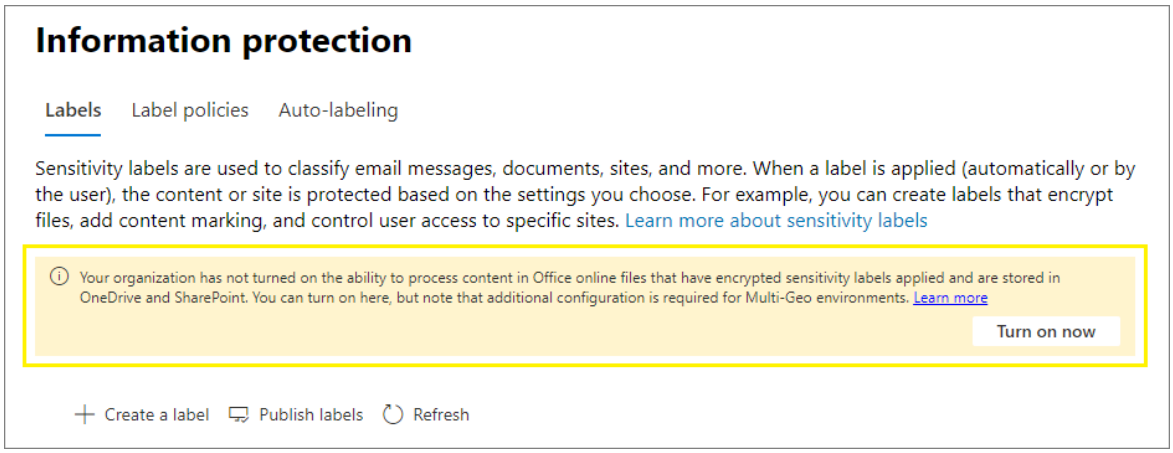
Use the compliance center to enable support for sensitivity labels

This option is the easiest way to enable sensitivity labels for SharePoint and OneDrive, but you must sign in as a global administrator for your tenant.

1. Sign in to the Microsoft 365 compliance center as a global administrator, and navigate to **Solutions** > **Information protection**

   If you don't immediately see this option, first select **Show all**.

2. If you see a message to turn on the ability to process content in Office online files, select **Turn on now**:



The command runs immediately and when the page is next refreshed, you no longer see the message or button.

> **NOTE**
> If you have Microsoft 365 Multi-Geo, you must use PowerShell to enable these capabilities for all your geo-locations. See the next section for details.

Use PowerShell to enable support for sensitivity labels

As an alternative to using the compliance center, you can enable support for sensitivity labels by using the Set-SPOTenant cmdlet from SharePoint Online PowerShell.

If you have Microsoft 365 Multi-Geo, you must use PowerShell to enable this support for all your geo-locations.

Prepare the SharePoint Online Management Shell

Before you run the PowerShell command to enable sensitivity labels for Office files in SharePoint and OneDrive, ensure that you're running SharePoint Online Management Shell version 16.0.19418.12000 or later. If you already have the latest version, you can skip to next procedure to run the PowerShell command.

1. If you have installed a previous version of the SharePoint Online Management Shell from PowerShell gallery, you can update the module by running the following cmdlet.

   ```
   Update-Module -Name Microsoft.Online.SharePoint.PowerShell
   ```

2. Alternatively, if you have installed a previous version of the SharePoint Online Management Shell from the Microsoft Download Center, you can also go to **Add or remove programs** and uninstall the SharePoint Online Management Shell.

3. In a web browser, go to the Download Center page and Download the latest SharePoint Online Management Shell.

4. Select your language and then click **Download**.

5. Choose between the x64 and x86 .msi file. Download the x64 file if you run the 64-bit version of Windows or the x86 file if you run the 32-bit version. If you don't know, see Which version of Windows operating system am I running?

6. After you have downloaded the file, run the file and follow the steps in the Setup Wizard.

Run the PowerShell command to enable support for sensitivity labels

To enable the new capabilities, use the Set-SPOTenant cmdlet with the *EnableAIPIntegration* parameter:

1. Using a work or school account that has global administrator or SharePoint admin privileges in Microsoft

365, connect to SharePoint. To learn how, see Getting started with SharePoint Online Management Shell.

Note: If you have Microsoft 365 Multi-Geo, use the -Url parameter with Connect-SPOService, and specify the SharePoint Online Administration Center site URL for one of your geo-locations.

2. Run the following command and press **Y** to confirm:

```
Set-SPOTenant -EnableAIPIntegration $true
```

3. For Microsoft 365 Multi-Geo: Repeat steps 1 and 2 for each of your remaining geo-locations.

Publishing and changing sensitivity labels

When you use sensitivity labels with SharePoint and OneDrive, keep in mind that you need to allow for replication time when you publish new sensitivity labels or update existing sensitivity labels. This is especially important for new labels that apply encryption.

For example: You create and publish a new sensitivity label that applies encryption and it very quickly appears in a user's desktop app. The user applies this label to a document and then uploads it to SharePoint or OneDrive. If the label replication hasn't completed for the service, the new capabilities won't be applied to that document on upload. As a result, the document won't be returned in search or for eDiscovery and the document can't be opened in Office for the web.

The following changes replicate within one hour: New and deleted sensitivity labels, and sensitivity label policy settings that include which labels are in the policy.

The following changes replicate within 24 hours: Changes to sensitivity label settings for existing labels.

Because the replication delay is only one hour for new sensitivity labels, you are unlikely to run into the scenario in the example. But as a safeguard, we recommend publishing new labels to just a few test users first, wait for an hour, and then verify the label behavior on SharePoint and OneDrive. As the final step, make the label available to more users by either adding more users to the existing label policy, or add the label to an existing label policy for your standard users. At the time your standard users see the label, it has already synchronized to SharePoint and OneDrive.

SharePoint Information Rights Management (IRM) and sensitivity labels

SharePoint Information Rights Management (IRM) is an older technology to protect files at the list and library level by applying encryption and restrictions when files are downloaded. This older protection technology is designed to prevent unauthorized users from opening the file while it's outside SharePoint.

In comparison, sensitivity labels provide the protection settings of visual markings (headers, footers, watermarks) in addition to encryption. The encryption settings support the full range of usage rights to restrict what users can do with the content, and the same sensitivity labels are supported for many scenarios. Using the same protection method with consistent settings across workloads and apps results in a consistent protection strategy.

However, you can use both protection solutions together and the behavior is as follows:

- If you upload a file with a sensitivity label that applies encryption, SharePoint can't process the content of these files so coauthoring, eDiscovery, DLP, and search are not supported for these files.
- If you label a file using Office on the web, any encryption settings from the label are enforced. For these files, coauthoring, eDiscovery, DLP, and search are supported.

- If you download a file that's labeled by using Office on the web, the label is retained and any encryption settings from the label are enforced rather than the IRM restriction settings.
- If you download an Office or PDF file that isn't encrypted with a sensitivity label, IRM settings are applied.
- If you have enabled any of the additional IRM library settings, which include preventing users from uploading documents that don't support IRM, these settings are enforced.

With this behavior, you can be assured that all Office and PDF files are protected from unauthorized access if they are downloaded, even if they aren't labeled. However, labeled files that are uploaded won't benefit from the new capabilities.

Search for documents by sensitivity label

Use the managed property **InformationProtectionLabelId** to find all documents in SharePoint or OneDrive that have a specific sensitivity label. Use the following syntax: `InformationProtectionLabelId:<GUID>`

For example, to search for all documents that have been labeled as "Confidential", and that label has a GUID of "8faca7b8-8d20-48a3-8ea2-0f96310a848e", in the search box, type:

```
InformationProtectionLabelId: 8faca7b8-8d20-48a3-8ea2-0f96310a848e
```

To get the GUIDs for your sensitivity labels, use the Get-Label cmdlet:

1. First, connect to Office 365 Security & Compliance Center PowerShell.

   For example, in a PowerShell session that you run as administrator, sign in with a global administrator account.

2. Then run the following command:

   ```
   Get-Label |ft Name, Guid
   ```

For more information about using managed properties, see Manage the search schema in SharePoint.

Remove encryption for a labeled document

There might be rare occasions when a SharePoint administrator needs to remove encryption from a document stored in SharePoint. Any user who has the Rights Management usage right of Export or Full Control assigned to them for that document can remove encryption that was applied by the Azure Rights Management service from Azure Information Protection. For example, users with either of these usage rights can replace a label that applies encryption with a label without encryption. Alternatively, a super user could download the file and save a local copy without the encryption.

As an alternative, a global admin or SharePoint admin can run the Unlock-SPOSensitivityLabelEncryptedFile cmdlet, which removes both the sensitivity label and the encryption. This cmdlet runs even if the admin doesn't have access permissions to the site or file, or if the Azure Rights Management service is unavailable.

For example:

```
Unlock-SPOSensitivityLabelEncryptedFile -FileUrl "https://contoso.com/sites/Marketing/Shared
Documents/Doc1.docx" -JustificationText "Need to decrypt this file"
```

Requirements:

- SharePoint Online Management Shell version 16.0.20616.12000 or later.

- The encryption has been applied by a sensitivity label with admin-defined encryption settings (the Assign permissions now label settings). Double Key Encryption is not supported for this cmdlet.

The justification text is added to the audit event of **Removed sensitivity label from file**, and the decryption action is also recorded in the protection usage logging for Azure Information Protection.

How to disable sensitivity labels for SharePoint and OneDrive (opt-out)

If you disable these new capabilities, files that you uploaded after you enabled sensitivity labels for SharePoint and OneDrive continue to be protected by the label because the label settings continue to be enforced. When you apply sensitivity labels to new files after you disable these new capabilities, full-text search, eDiscovery, and coauthoring will no longer work.

To disable these new capabilities, you must use PowerShell. Using the SharePoint Online Management Shell and the Set-SPOTenant cmdlet, specify the same *EnableAIPIntegration* parameter as described in the Use PowerShell to enable support for sensitivity labels section. But this time, set the parameter value to false and press **Y** to confirm:

```
Set-SPOTenant -EnableAIPIntegration $false
```

If you have Microsoft 365 Multi-Geo, you must run this command for each of your geo-locations.

Next steps

After you've enabled sensitivity labels for Office files in SharePoint and OneDrive, consider automatically labeling these files by using auto-labeling policies. For more information, see Apply a sensitivity label to content automatically.

Need to share your labeled and encrypted documents with people outside your organization? See Sharing encrypted documents with external users.

Manage sensitivity labels in Office apps

2/18/2021 • 20 minutes to read • Edit Online

> *Microsoft 365 licensing guidance for security & compliance*.

When you have published sensitivity labels from the Microsoft 365 compliance center or equivalent labeling center, they start to appear in Office apps for users to classify and protect data as it's created or edited.

Use the information in this article to help you successfully manage sensitivity labels in Office apps. For example, identify the minimum versions of apps you need to support built-in labeling, and understand interactions with the Azure Information Protection unified labeling client and compatibility with other apps and services.

Labeling client for desktop apps

To use sensitivity labels that are built into Office desktop apps for Windows and Mac, you must use a subscription edition of Office. This labeling client doesn't support standalone editions of Office, such as Office 2016 or Office 2019.

To use sensitivity labels with these standalone editions of Office on Windows computers, install the Azure Information Protection unified labeling client.

Support for sensitivity label capabilities in apps

For each capability, the following tables list the minimum Office version that you need to support sensitivity labels using built-in labeling. Or, if the label capability is in public preview or under review for a future release. Use the Microsoft 365 roadmap for details about future releases.

New versions of Office apps are made available at different times for different update channels. For more information, including how to configure your update channel so that you can test a new labeling capability that you're interested in, see Overview of update channels for Microsoft 365 Apps. New capabilities that are in private preview are not included in the table but you might be able to join these previews by nominating your organization for the Microsoft Information Protection private preview program.

> **NOTE**
> The names of the update channels for Office apps have recently changed. For example, Monthly Channel is now Current Channel, and Office Insider is now Beta Channel. For more information, see Changes to update channels for Microsoft 365 Apps.

Office for iOS and Office for Android: Sensitivity labels are built into the Office app.

Additional capabilities are available when you install the Azure Information Protection unified labeling client, which runs on Windows computers only. For these details, see Compare the labeling clients for Windows computers.

Sensitivity label capabilities in Word, Excel, and PowerPoint

The numbers listed are the minimum Office application version required for each capability.

CAPABILITY	WINDOWS	MAC	IOS	ANDROID	WEB
Manually apply, change, or remove label	1910+	16.21+	2.21+	16.0.11231+	Yes - opt-in
Apply a default label	1910+	16.21+	2.21+	16.0.11231+	Yes - opt-in

Apply a sensitivity label to content automatically	2009+	16.44+	Under review	Under review	Yes

Office built-in labeling client and other labeling solutions

The Office built-in labeling client downloads sensitivity labels and sensitivity label policy settings from the following admin centers:

- Microsoft 365 compliance center

- Microsoft 365 security center
- Office 365 Security & Compliance Center

To use the Office built-in labeling client, you must have one or more label policies published to users from one of the listed admin centers and a supported version of Office.

If both of these conditions are met but you need to turn off the Office built-in labeling client, use the following Group Policy setting:

1. Navigate to **User Configuration/Administrative Templates/Microsoft Office 2016/Security Settings**.
2. Set **Use the Sensitivity feature in Office to apply and view sensitivity labels** to **0**.

Deploy this setting by using Group Policy, or by using the Office cloud policy service. The setting takes effect when Office apps restart.

Office built-in labeling client and the Azure Information Protection client

If users have one of the Azure Information Protection clients installed (unified labeling client or classic client), by default, the built-in labeling client is turned off in their Office apps.

To use built-in labeling rather than the Azure Information Protection client for Office apps, use the instructions from the previous section but set the Group Policy setting **Use the Sensitivity feature in Office to apply and view sensitivity labels** to **1**.

Alternatively, disable or remove the Office Add-in, **Azure Information Protection**. This method is suitable for a single computer, and ad-hoc testing. For instructions, see View, manage, and install add-ins in Office programs.

When you disable or remove this Office Add-in, the Azure Information Protection client remains installed so that you can continue to label files outside your Office apps. For example, by using File Explorer, or PowerShell.

For information about which features are supported by the Azure Information Protection clients and the Office built-in labeling client, see Choose which labeling client to use for Windows computers from the Azure Information Protection documentation.

Office file types supported

Office apps that have built-in labeling for Word, Excel, and PowerPoint files support the Open XML format (such as .docx and .xlsx) but not the Microsoft Office 97-2003 format (such as .doc and .xls), Open Document Format (such as .odt and .ods), or other formats. When a file type is not supported for built-in labeling, the **Sensitivity** button is not available in the Office app.

The Azure Information Protection unified labeling client supports both the Open XML format and the Microsoft Office 97-2003 format. For more information, see File types supported by the Azure Information Protection unified labeling client from that client's admin guide.

For other labeling solutions, check their documentation for file types supported.

Protection templates and sensitivity labels

Administrator-defined protection templates, such as those you define for Office 365 Message Encryption, aren't visible in Office apps when you're using built-in labeling. This simplified experience reflects that there's no need to select a protection template, because the same settings are included with sensitivity labels that have encryption enabled.

If you need to convert existing protection templates to labels, use the Azure portal and the following instructions: To convert templates to labels.

Information Rights Management (IRM) options and sensitivity labels

Sensitivity labels that you configure to apply encryption remove the complexity from users to specify their own encryption settings. In many Office apps, these individual encryption settings can still be manually configured by users by using Information Rights Management (IRM) options. For example, for Windows apps:

- For a document: **File** > **Info** > **Protect Document** > **Restrict Access**
- for an email: From the **Options** tab > **Encrypt**

When users initially label a document or email, they can always override your label configuration settings with their own encryption settings. For example:

- A user applies the **Confidential \ All Employees** label to a document and this label is configured to apply encryption settings for all users in the organization. This user then manually configures the IRM settings to restrict access to a user outside your organization. The end result is a document that's labeled **Confidential \ All Employees** and encrypted, but users in your organization can't open it as expected.
- A user applies the **Confidential \ Recipients Only** label to an email and this email is configured to apply the encryption setting of **Do Not Forward**. This user then manually configures the IRM settings so that the email is unrestricted. The end result is the email can be forwarded by recipients, despite having the **Confidential \ Recipients Only** label.
- A user applies the **General** label to a document, and this label isn't configured to apply encryption. This user then manually configures the IRM settings to restrict access to the document. The end result is a document that's labeled **General** but that also applies encryption so that some users can't open it as expected.

If the document or email is already labeled, a user can do any of these actions if the content isn't already encrypted, or they have the usage right Export or Full Control.

For a more consistent label experience with meaningful reporting, provide appropriate labels and guidance for users to apply only labels to protect documents. For example:

- For exception cases where users must assign their own permissions, provide labels that let users assign their own permissions.
- Instead of users manually removing encryption after selecting a label that applies encryption, provide a sublabel alternative when users need a label with the same classification, but no encryption. Such as:
  - **Confidential \ All Employees**
  - **Confidential \ Anyone (no encryption)**

> **NOTE**
> If users manually remove encryption from a labeled document that's stored in SharePoint or OneDrive and you've enabled sensitivity labels for Office files in SharePoint and OneDrive, the label encryption will be automatically restored the next time the document is accessed or downloaded.

Apply sensitivity labels to files, emails, and attachments

Users can apply just one label at a time for each document or email.

When you label an email message that has attachments, the attachments inherit the label only if the label that you apply to the email message applies encryption and the attachment is an Office document isn't already encrypted. Because the inherited label applies encryption, the attachment becomes newly encrypted.

An attachment doesn't inherit the labels from the email message when the label applied to the email message

doesn't apply encryption or the attachment is already encrypted.

Examples of label inheritance, where the label **Confidential** applies encryption and the label **General** doesn't apply encryption:

- A user creates a new email message and applies the **Confidential** label to this message. They then add a Word document that isn't labeled or encrypted. As a result of inheritance, the document is newly labeled **Confidential** and now has encryption applied from that label.
- A user creates a new email message and applies the **Confidential** label to this message. They then add a Word document that is labeled **General** and this file isn't encrypted. As a result of inheritance, the document gets relabeled as **Confidential** and now has encryption applied from that label.

Sensitivity label compatibility

With RMS-enlightened apps: If you open a labeled and encrypted document or email in an RMS-enlightened application that doesn't support sensitivity labels, the app still enforces encryption and rights management.

With the Azure Information Protection client: You can view and change sensitivity labels that you apply to documents and emails with the Office built-in labeling client by using the Azure Information Protection client, and the other way around.

With other versions of Office: Any authorized user can open labeled documents and emails in other versions of Office. However, you can only view or change the label in supported Office versions or by using the Azure Information Protection client. Supported Office app versions are listed in the previous section.

Support for SharePoint and OneDrive files protected by sensitivity labels

To use the Office built-in labeling client with Office on the web for documents in SharePoint or OneDrive, make sure you've enabled sensitivity labels for Office files in SharePoint and OneDrive.

Support for external users and labeled content

When you label a document or email, the label is stored as metadata that includes your tenant and a label GUID. When a labeled document or email is opened by an Office app that supports sensitivity labels, this metadata is read and only if the user belongs to the same tenant, the label displays in their app. For example, for built-in labeling for Word, PowerPoint, and Excel, the label name displays on the status bar.

This means that if you share documents with another organization that uses different label names, each organization can apply and see their own label applied to the document. However, the following elements from an applied label are visible to users outside your organization:

- Content markings. When a label applies a header, footer, or watermark, these are added directly to the content and remain visible until somebody modifies or deletes them.
- The name and description of the underlying protection template from a label that applied encryption. This information displays in a message bar at the top of the document, to provide information about who is authorized to open the document, and their usage rights for that document.

Sharing encrypted documents with external users

In addition to restricting access to users in your own organization, you can extend access to any other user who has an account in Azure Active Directory. However, if your organization uses Conditional Access policies, see the next section for additional considerations.

All Office apps and other RMS-enlightened application can open encrypted documents after the user has

successfully authenticated.

If external users do not have an account in Azure Active Directory, they can authenticate by using guest accounts in your tenant. These guest accounts can also be used to access shared documents in SharePoint or OneDrive when you have enabled sensitivity labels for Office files in SharePoint and OneDrive:

- One option is to create these guest accounts yourself. You can specify any email address that these users already use. For example, their Gmail address.

  The advantage of this option is that you can restrict access and rights to specific users by specifying their email address in the encryption settings. The downside is the administration overhead for the account creation and coordination with the label configuration.

- Another option is to use SharePoint and OneDrive integration with Azure AD B2B (Preview) so that guest accounts are automatically created when your users share links.

  The advantage of this option is minimum administrative overhead because the accounts are created automatically, and simpler label configuration. For this scenario, you must select the encryption option Add any authenticated user because you won't know the email addresses in advance. The downside is that this setting doesn't let you restrict access and usage rights to specific users.

External users can also use a Microsoft account to open encrypted documents when they use Windows and Microsoft 365 Apps (formerly Office 365 apps) or the standalone edition of Office 2019. More recently supported for other platforms, Microsoft accounts are also supported for opening encrypted documents on macOS (Microsoft 365 Apps, version 16.42+), Android (version 16.0.13029+), and iOS (version 2.42+). For example, a user in your organization shares an encrypted document with a user outside your organization, and the encryption settings specify a Gmail email address for the external user. This external user can create their own Microsoft account that uses their Gmail email address. Then, after signing in with this account, they can open the document and edit it, according to the usage restrictions specified for them. For a walkthrough example of this scenario, see Opening and editing the protected document.

> **NOTE**
> The email address for the Microsoft account must match the email address that's specified to restrict access for the encryption settings.

When a user with a Microsoft account opens an encrypted document in this way, it automatically creates a guest account for the tenant if a guest account with the same name doesn't already exist. When the guest account exists, it can then be used to open documents in SharePoint and OneDrive by using Office on the web, in addition to opening encrypted documents from the supported desktop and mobile Office apps.

However, the automatic guest account is not created immediately in this scenario, because of replication latency. If you specify personal email addresses as part of your label encryption settings, we recommend that you create corresponding guest accounts in Azure Active Directory. Then let these users know that they must use this account to open an encrypted document from your organization.

> **TIP**
> Because you can't be sure that external users will be using a supported Office client app, sharing links from SharePoint and OneDrive after creating guest accounts (for specific users) or when you use SharePoint and OneDrive integration with Azure AD B2B (for any authenticated user) is a more reliable method to support secure collaboration with external users.

Conditional Access policies

If your organization has implemented Azure Active Directory Conditional Access policies, check the configuration of those policies. If the policies include Azure Information Protection and the policy extends to

external users, those external users must have a guest account in your tenant even if they have an Azure AD account in their own tenant.

Without this guest account, they can't open the encrypted document and see an error message. The message text might inform them that their account needs to be added as an external user in the tenant, with the incorrect instruction for this scenario to **Sign out and sign in again with a different Azure Active Directory user account**.

If you can't create and configure guest accounts in your tenant for external users who need to open documents that are encrypted by your labels, you must either remove Azure Information Protection from the Conditional Access policies, or exclude external users from the policies.

For more information about Conditional Access and Azure Information Protection, the encryption service used by sensitivity labels, see the frequently asked question, I see Azure Information Protection is listed as an available cloud app for conditional access—how does this work?

When Office apps apply content marking and encryption

Office apps apply content marking and encryption with a sensitivity label differently, depending on the app you use.

APP	CONTENT MARKING	ENCRYPTION
Word, Excel, PowerPoint on all platforms	Immediately	Immediately
Outlook for PC and Mac	After Exchange Online sends the email	Immediately
Outlook on the web, iOS, and Android	After Exchange Online sends the email	After Exchange Online sends the email

Solutions that apply sensitivity labels to files outside Office apps do so by applying labeling metadata to the file. In this scenario, content marking from the label's configuration isn't inserted into the file but encryption is applied.

When those files are opened in an Office desktop app, the content markings are automatically applied by the Azure Information Protection unified labeling client. The content markings are not automatically applied when you use built-in labeling for desktop, mobile, or web apps.

Scenarios that include applying a sensitivity label outside Office apps include:

- The scanner, File Explorer, and PowerShell from the Azure Information Protection unified labeling client
- Auto-labeling policies for SharePoint and OneDrive
- Exported labeled and encrypted data from Power BI
- Microsoft Cloud App Security

For these scenarios, using their Office apps, a user with built-in labeling can apply the label's content markings by temporarily removing or replacing the current label and then reapplying the original label.

Dynamic markings with variables

IMPORTANT

Currently, not all apps on all platforms support dynamic content markings that you can specify for your headers, footers, and watermarks. For apps that don't support this capability, they apply the markings as the original text specified in the label configuration, rather than resolving the variables.

The Azure Information Protection unified labeling client supports dynamic markings. For labeling built in to Office, see the tables in the capabilities section on this page.

When you configure a sensitivity label for content markings, you can use the following variables in the text string for your header, footer, or watermark:

VARIABLE	DESCRIPTION	EXAMPLE WHEN LABEL APPLIED
`${Item.Label}`	Label display name of the label applied	**General**
`${Item.Name}`	File name or email subject of the content being labeled	**Sales.docx**
`${Item.Location}`	Path and file name of the document being labeled, or the email subject for an email being labeled	**\\Sales\2020\Q3\Report.docx**
`${User.Name}`	Display name of the user applying the label	**Richard Simone**
`${User.PrincipalName}`	Azure AD user principal name (UPN) of the user applying the label	**rsimone@contoso.com**
`${Event.DateTime}`	Date and time when the content is labeled, in the local time zone of the user applying the label	**8/10/2020 1:30 PM**

NOTE

The syntax for these variables is case-sensitive.

Setting different visual markings for Word, Excel, PowerPoint, and Outlook

As an additional variable, you can configure visual markings per Office application type by using an "If.App" variable statement in the text string, and identify the application type by using the values **Word**, **Excel**, **PowerPoint**, or **Outlook**. You can also abbreviate these values, which is necessary if you want to specify more than one in the same If.App statement.

NOTE

For completeness, instructions for Outlook are included, although currently supported only by the Azure Information Protection unified labeling client.

Use the following syntax:

```
${If.App.<application type>}<your visual markings text> ${If.End}
```

As with the other dynamic visual markings, the syntax is case-sensitive.

Examples:

- **Set header text for Word documents only:**

  ```
  ${If.App.Word}This Word document is sensitive ${If.End}
  ```

  In Word document headers only, the label applies the header text "This Word document is sensitive". No header text is applied to other Office applications.

- **Set footer text for Word, Excel, and Outlook, and different footer text for PowerPoint:**

  ```
  ${If.App.WXO}This content is confidential. ${If.End}${If.App.PowerPoint}This presentation is confidential. ${If.End}
  ```

  In Word, Excel, and Outlook, the label applies the footer text "This content is confidential." In PowerPoint, the label applies the footer text "This presentation is confidential."

- **Set specific watermark text for Word and PowerPoint, and then watermark text for Word, Excel, and PowerPoint:**

  ```
  ${If.App.WP}This content is ${If.End}Confidential
  ```

  In Word and PowerPoint, the label applies the watermark text "This content is Confidential". In Excel, the label applies the watermark text "Confidential". In Outlook, the label doesn't apply any watermark text because watermarks as visual markings are not supported for Outlook.

Require users to apply a label to their email and documents

> **IMPORTANT**
> Also known as mandatory labeling, not all apps on all platforms currently support the policy setting of **Require users to apply a label to their email and documents**.
>
> The Azure Information Protection unified labeling client supports mandatory labeling and for labeling built in to Office apps, see the tables in the capabilities section on this page.

When this policy setting is selected, users assigned the policy must select and apply a sensitivity label under the following scenarios:

- For the Azure Information Protection unified labeling client:
  - For documents (Word, Excel, PowerPoint): When an unlabeled document is saved or users close the document.
  - For emails (Outlook): At the time users send an unlabeled message.
- For labeling built in to Office apps:
  - For documents ((Word, Excel, PowerPoint): When an unlabeled document is opened or saved.
  - For emails (Outlook): At the time users send an unlabeled email message.

Additional information for built-in labeling:

- When users are prompted to add a sensitivity label because they open an unlabeled document, they can add a label or choose to open the document in read-only mode.
- When mandatory labeling is in effect, users can't remove sensitivity labels from documents, but can change an existing label.

For guidance about when to use this setting, see the information about policy settings.

End-user documentation

- Apply sensitivity labels to your documents and email within Office
- Known issues when you apply sensitivity labels to your Office files

Encryption

2/18/2021 • 4 minutes to read • Edit Online

Encryption is an important part of your file protection and information protection strategy. This article provides an overview of encryption for Office 365. Get help with encryption tasks like how to set up encryption for your organization and how to password-protect Office documents.

- For information about certificates and technologies like TLS, see Technical reference details about encryption in Office 365.
- For information about how to configure or set up encryption for your organization, see Set up encryption in Office 365 Enterprise.

What is encryption, and how does it work in Office 365?

The encryption process encodes your data (referred to as plaintext) into ciphertext. Unlike plaintext, ciphertext can't be used by people or computers unless and until the ciphertext is decrypted. Decryption requires an encryption key that only authorized users have. Encryption helps ensure that only authorized recipients can decrypt your content. Content includes files, email messages, calendar entries, and so on.

Encryption by itself doesn't prevent content interception. Encryption is part of a larger information protection strategy for your organization. By using encryption, you help ensure that only authorized parties can use the encrypted data.

You can have multiple layers of encryption in place at the same time. For example, you can encrypt email messages and also the communication channels through which your email flows. With Office 365, your data is encrypted at rest and in transit, using several strong encryption protocols, and technologies that include Transport Layer Security/Secure Sockets Layer (TLS/SSL), Internet Protocol Security (IPSec), and Advanced Encryption Standard (AES).

Encryption for data at rest and data in transit

Examples of data at rest include files that you've uploaded to a SharePoint library, Project Online data, documents that you've uploaded in a Skype for Business meeting, email messages and attachments that you've stored in folders in your mailbox, and files you've uploaded to OneDrive for Business.

Examples of data in transit include mail messages that are in the process of being delivered, or conversations that are taking place in an online meeting. In Office 365, data is in transit whenever a user's device is communicating with a Microsoft server, or when a Microsoft server is communicating with another server.

With Office 365, multiple layers and kinds of encryption work together to secure your data. The following table includes some examples, with links to additional information.

KINDS OF CONTENT	ENCRYPTION TECHNOLOGIES	RESOURCES TO LEARN MORE
Files on a device. These files can include email messages saved in a folder, Office documents saved on a computer, tablet, or phone, or data saved to the Microsoft cloud. Double Key Encryption for Microsoft 365

2/18/2021 • 17 minutes to read • Edit Online

Applies to: Double Key Encryption for Microsoft 365, Microsoft 365 Compliance, Azure Information Protection

Instructions for: Azure Information Protection unified labeling client for Windows

Service description for: Microsoft 365 Compliance

Double Key Encryption (DKE) uses two keys together to access protected content. Microsoft stores one key in Microsoft Azure, and you hold the other key. You maintain full control of one of your keys using the Double Key Encryption service. You apply protection using The Azure Information Protection unified labeling client to your highly sensitive content.

Double Key Encryption supports both cloud and on-premises deployments. These deployments help to ensure that encrypted data remains opaque wherever you store the protected data.

For more information about the default, cloud-based tenant root keys, see Planning and implementing your Azure Information Protection tenant key.

When your organization should adopt DKE

Double Key Encryption is intended for your most sensitive data that is subject to the strictest protection requirements. DKE is not intended for all data. In general, you'll be using Double Key Encryption to protect only a small part of your overall data. You should do due diligence in identifying the right data to cover with this solution before you deploy. In some cases, you might need to narrow your scope and make use of other solutions for most your data such as Microsoft Information Protection with Microsoft-managed keys or BYOK. These solutions are sufficient for documents that aren't subject to enhanced protections and regulatory requirements. Also, these solutions enable you to use the most powerful Office 365 services; services that you can't use with DKE encrypted content. For example:

- Transport rules including anti-malware and spam that require visibility into the attachment
- Microsoft Delve
- eDiscovery
- Content search and indexing
- Office Web Apps including coauthoring functionality

Any external applications or services that are not integrated with DKE through the MIP SDK will be unable to perform actions on the encrypted data.

The Microsoft Information Protection SDK 1.7+ supports Double Key Encryption; applications that integrate with our SDK will be able to reason over this data with sufficient permissions and integrations in place.

We recommend organizations use Microsoft Information protection capabilities (classification and labeling) to protect most of their sensitive data and only use DKE for their mission-critical data. Double Key Encryption is relevant for sensitive data in highly regulated industries such as Financial services and Healthcare.

If your organizations have any of the following requirements, you can use DKE to help secure your content:

- You want to ensure that *only you* can ever decrypt protected content, under all circumstances.
- You don't want Microsoft to have access to protected data on its own.

- You have regulatory requirements to hold keys within a geographical boundary. All of the keys that you hold for data encryption and decryption are maintained in your data center.

System and licensing requirements for DKE

Double Key Encryption for Microsoft 365 comes with Microsoft 365 E5. If you don't have a Microsoft 365 E5 license, you can sign up for a trial. For more information about these licenses, see Microsoft 365 licensing guidance for security & compliance.

Azure Information Protection. DKE works with sensitivity labels and requires Azure Information Protection.

DKE sensitivity labels are made available to end users through the sensitivity ribbon in Office Desktop Apps. Install these prerequisites on each client computer where you want to protect and consume protected documents.

Microsoft Office Apps for enterprise version *.12711 or later (Desktop versions of Word, PowerPoint, and Excel) on Windows.

Azure Information Protection Unified Labeling Client versions 2.7.93.0 or later. Download and install the Unified Labeling client from the Microsoft download center.

Supported environments for storing and viewing DKE-protected content

Supported applications. Microsoft 365 Apps for enterprise clients on Windows, including Word, Excel, and PowerPoint.

Online content support. Documents and files stored online in both Microsoft SharePoint and OneDrive for Business are supported. You can share encrypted content by email, but you can't view encrypted documents and files online. Instead, you must view protected content using the desktop apps on your local computer.

Overview of deploying DKE

You'll follow these general steps to set up DKE. Once you've completed these steps, your end users will can protect your highly sensitive data with Double Key Encryption.

1. Deploy the DKE service as described in this article.
2. Create a label with Double Key Encryption. Navigate to Information protection under the Microsoft 365 compliance center and create a new label with Double Key Encryption. See Restrict access to content by using sensitivity labels to apply encryption.
3. Use Double Key Encryption labels. Protect data by selecting the Double Key Encrypted label from the Sensitivity ribbon in Microsoft Office.

There are several ways you can complete some of the steps to deploy Double Key Encryption. This article provides detailed instructions so that less experienced admins successfully deploy the service. If you're comfortable doing so, you can choose to use your own methods.

Deploy DKE

This article and the deployment video use Azure as the deployment destination for the DKE service. If you're deploying to another location, you'll need to provide your own values.

Watch the Double Key Encryption deployment video to see a step-by-step overview of the concepts in this article. The video takes about 18 minutes to complete.

You'll follow these general steps to set up Double Key Encryption for your organization.

1. Install software prerequisites for the DKE service
2. Clone the Double Key Encryption GitHub repository
3. Modify application settings
4. Generate test keys
5. Build the project
6. Deploy the DKE service and publish the key store
7. Validate your deployment
8. Register your key store
9. Create sensitivity labels using DKE
10. Enable DKE in your client
11. Migrate protected files from HYOK labels to DKE labels

When you're done, you can encrypt documents and files using DKE. For information, see Apply sensitivity labels to your files and email in Office.

Install software prerequisites for the DKE service

Install these prerequisites on the computer where you want to install the DKE service.

.NET Core 3.1 SDK. Download and install the SDK from Download .NET Core 3.1.

Visual Studio Code. Download Visual Studio Code from https://code.visualstudio.com/. Once installed, run Visual Studio Code and select **View** > **Extensions**. Install these extensions.

- C# for Visual Studio Code
- NuGet Package Manager

Git resources. Download and install one of the following.

- Git
- GitHub Desktop
- GitHub Enterprise

OpenSSL You must have OpenSSL installed to generate test keys after you deploy DKE. Make sure you're invoking it correctly from your environment variables path. For example, see "Add the installation directory to PATH" at https://www.osradar.com/install-openssl-windows/ for details.

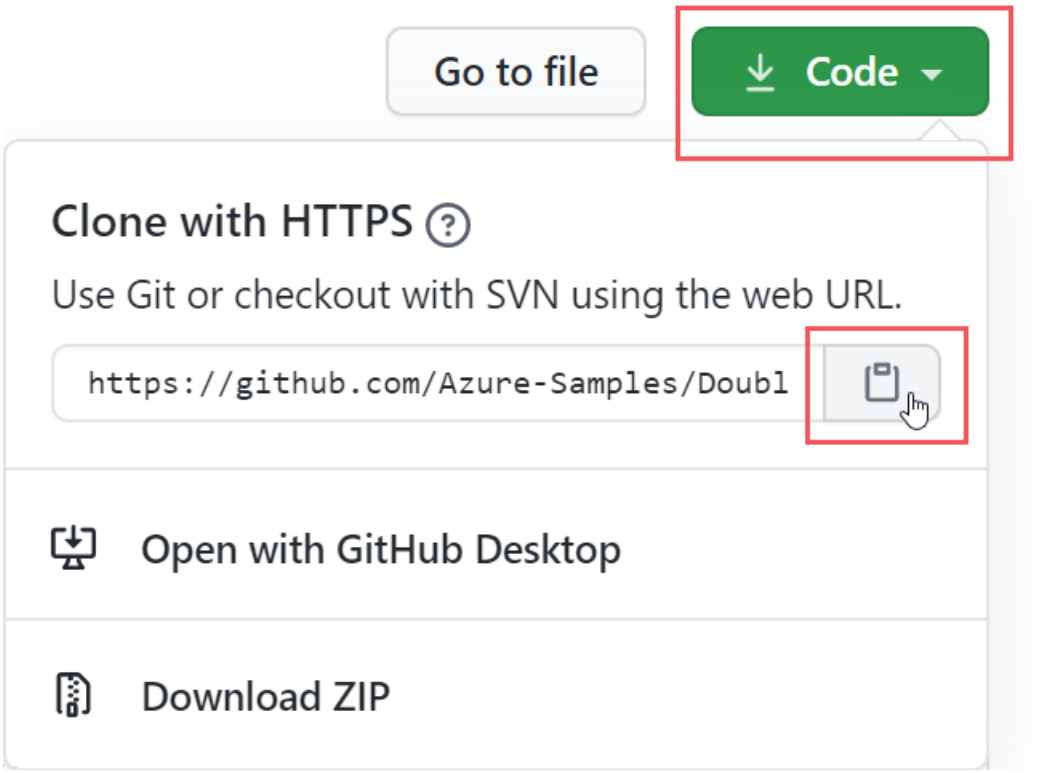
Clone the DKE GitHub repository

Microsoft supplies the DKE source files in a GitHub repository. You clone the repository to build the project locally for your organization's use. The DKE GitHub repository is located at https://github.com/Azure-Samples/DoubleKeyEncryptionService.

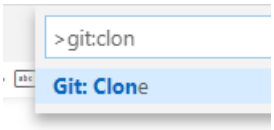
The following instructions are intended for inexperienced git or Visual Studio Code users:

1. In your browser, go to: https://github.com/Azure-Samples/DoubleKeyEncryptionService.
2. Towards the right side of the screen, select **Code**. Your version of the UI might show a **Clone or download** button. Then, in the dropdown that appears, select the copy icon to copy the URL to your clipboard.

   For example:



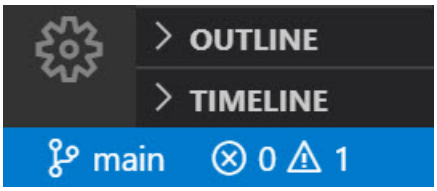
3. In Visual Studio Code, select **View** > **Command Palette** and select **Git: Clone**. To jump to the option in the list, start typing `git: clone` to filter the entries and then select it from the drop-down. For example:



4. In the text box, paste the URL that you copied from Git and select **Clone from GitHub**.

5. In the **Select Folder** dialog that appears, browse to and select a location to store the repository. At the prompt, select **Open**.

   The repository opens in Visual Studio Code, and displays the current Git branch at the bottom left. For example, The branch should be **main**. For example:



6. If you're not on the main branch, you'll need to select it. In Visual Studio Code, select the branch and choose **main** from the list of branches that displays.

   > **IMPORTANT**
   > Selecting the main branch ensures that you have the correct files to build the project. If you don't choose the correct branch your deployment will fail.

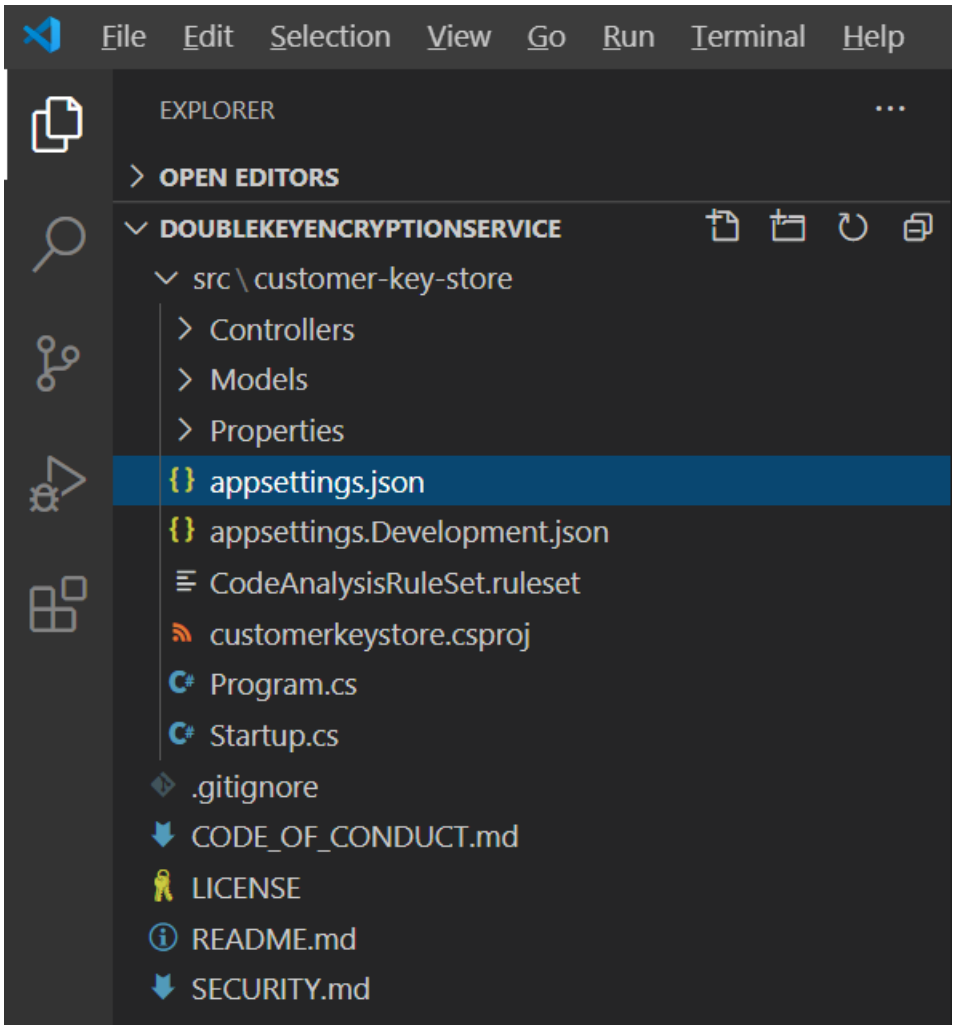
You now have your DKE source repository set up locally. Next, modify application settings for your organization.

Modify application settings

To deploy the DKE service, you must modify the following types of application settings:

- Key access settings
- Tenant and key settings

You modify application settings in the appsettings.json file. This file is located in the DoubleKeyEncryptionService repo you cloned locally under DoubleKeyEncryptionService\src\customer-key-store. For example, in Visual Studio Code, you can browse to the file as shown in the following picture.



Key access settings

Choose whether to use email or role authorization. DKE supports only one of these authentication methods at a time.

- **Email authorization**. Allows your organization to authorize access to keys based on email addresses only.
- **Role authorization**. Allows your organization to authorize access to keys based on Active Directory groups, and requires that the web service can query LDAP.

To set key access settings for DKE using email authorization

1. Open the **appsettings.json** file and locate the `AuthorizedEmailAddress` setting.
2. Add the email address or addresses that you want to authorize. Separate multiple email addresses with double quotes and commas. For example:

   ```
   "AuthorizedEmailAddress": ["email1@company.com", "email2@company.com ", "email3@company.com"]
   ```

3. Locate the `LDAPPath` setting and remove the text `If you use role authorization (AuthorizedRoles) then this is the LDAP path.` between the double

quotes. Leave the double quotes in place. When you're finished, the setting should look like this.

```
"LDAPPath": ""
```

4. Locate the `AuthorizedRoles` setting and delete the entire line.

This image shows the **appsettings.json** file correctly formatted for email authorization.

To set key access settings for DKE using role authorization

1. Open the **appsettings.json** file and locate the `AuthorizedRoles` setting.
2. Add the Active Directory group names you want to authorize. Separate multiple group names with double quotes and commas. For example:

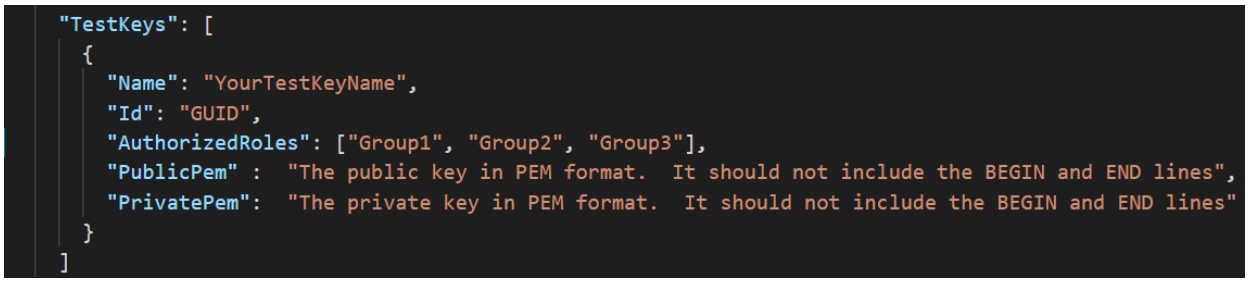
```
"AuthorizedRoles": ["group1", "group2", "group3"]
```

3. Locate the `LDAPPath` setting and add the Active Directory domain. For example:

```
"LDAPPath": "contoso.com"
```

4. Locate the `AuthorizedEmailAddress` setting and delete the entire line.

This image shows the **appsettings.json** file correctly formatted for role authorization.



Tenant and key settings

DKE tenant and key settings are located in the **appsettings.json** file.

To configure tenant and key settings for DKE

1. Open the **appsettings.json** file.
2. Locate the `ValidIssuers` setting and replace `<tenantid>` with your tenant ID. You can locate your tenant ID by going to the Azure portal and viewing the tenant properties. For example:

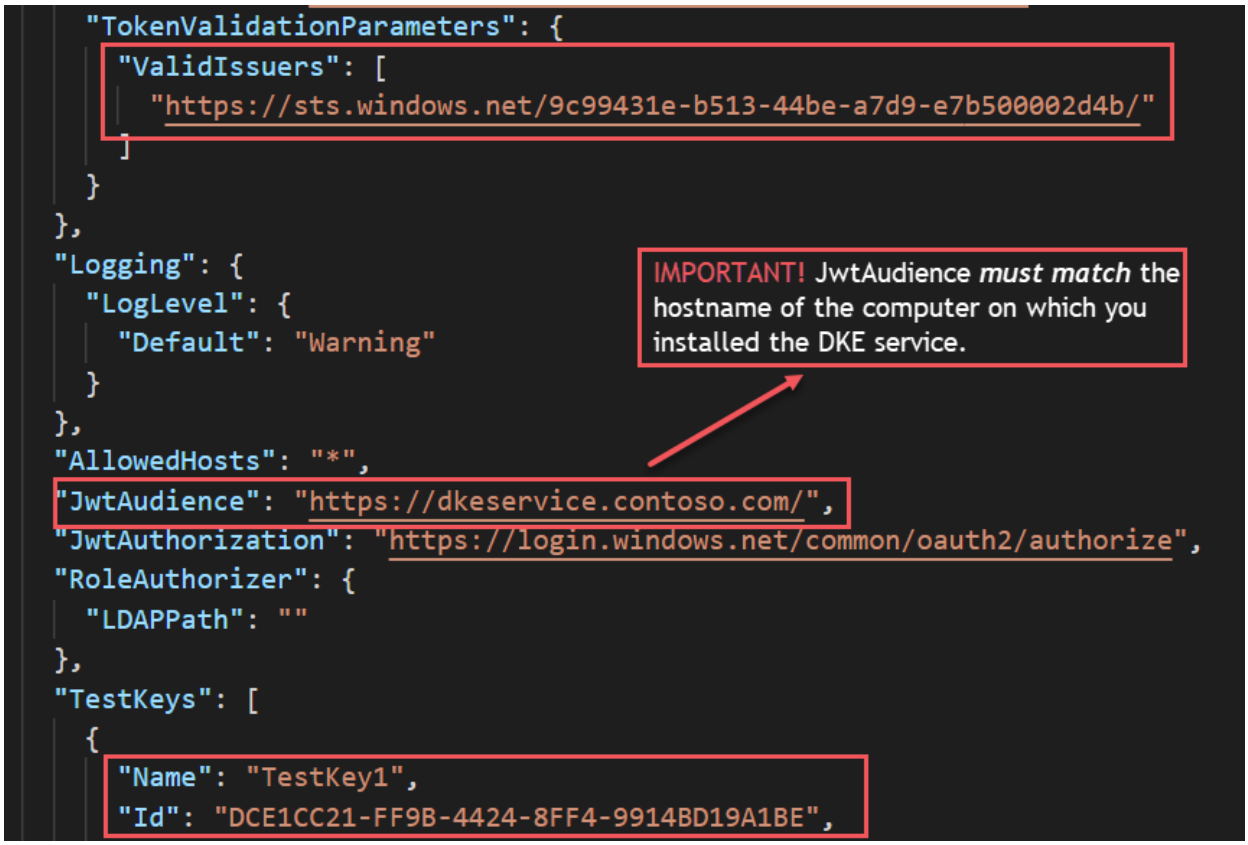
```
"ValidIssuers": [
  "https://sts.windows.net/9c99431e-b513-44be-a7d9-e7b500002d4b/"
]
```

Locate the `JwtAudience`. Replace `<yourhostname>` with the hostname of the machine where the DKE service will run. For example:

> **IMPORTANT**
> The value for `JwtAudience` must match the name of your host *exactly*. You may use **localhost:5001** while debugging. However, When you're done debugging, make sure to update this value to the server's hostname.

- `TestKeys:Name`. Enter a name for your key. For example: `TestKey1`
- `TestKeys:Id`. Create a GUID and enter it as the `TestKeys:ID` value. For example, `DCE1CC21-FF9B-4424-8FF4-9914BD19A1BE`. You can use a site like Online GUID Generator to randomly generate a GUID.

This image shows the correct format for tenant and keys settings in **appsettings.json**. `LDAPPath` is configured for role authorization.



Generate test keys

Once you have your application settings defined, you're ready to generate public and private test keys.

To generate keys:

1. From the Windows Start menu, run the OpenSSL Command Prompt.
2. Change to the folder where you want to save the test keys. The files you create by completing the steps in this task are stored in the same folder.
3. Generate the new test key.

```
openssl req -x509 -newkey rsa:2048 -keyout key.pem -out cert.pem -days 365
```

4. Generate the private key.

```
openssl rsa -in key.pem -out privkeynopass.pem
```

5. Generate the public key.

```
openssl rsa -in key.pem -pubout > pubkeyonly.pem
```

6. In a text editor, open **pubkeyonly.pem**. Copy all of the content in the **pubkeyonly.pem** file, except the first and last lines, into the `PublicPem` section of the **appsettings.json** file.

7. In a text editor, open **privkeynopass.pem**. Copy all of the content in the **privkeynopass.pem** file, except the first and last lines, into the `PrivatePem` section of the **appsettings.json** file.

8. Remove all blank spaces and newlines in both the `PublicPem` and `PrivatePem` sections.

> **IMPORTANT**
> When you copy this content, do not delete any of the PEM data.

9. In Visual Studio Code, browse to the **Startup.cs** file. This file is located in the DoubleKeyEncryptionService repo you cloned locally under DoubleKeyEncryptionService\src\customer-key-store.

10. Locate the following lines:

```
    #if USE_TEST_KEYS
    #error !!!!!!!!!!!!!!!!!!!! Use of test keys is only supported for testing,
    DO NOT USE FOR PRODUCTION !!!!!!!!!!!!!!!!!!!!!!!!!!!!!
    services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();
    #endif
```

11. Replace these lines with the following text:

```
services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();
```

The end results should look similar to the following.

```
        services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();

        services.AddTransient<ippw.KeyManager, ippw.KeyManager>();

        services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
```

Now you're ready to build your DKE project.

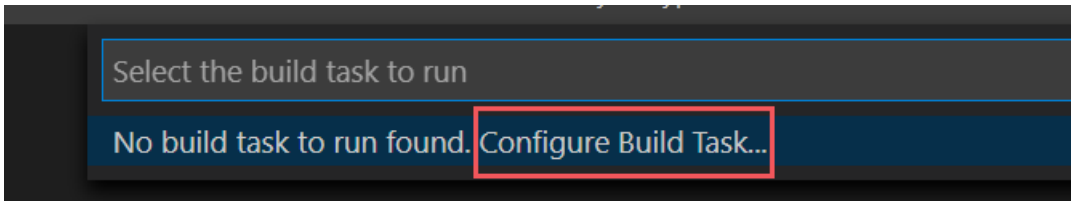
Build the project

Use the following instructions to build the DKE project locally:

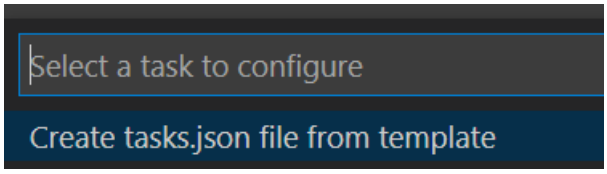
1. In Visual Studio Code, in the DKE service repository, select **View** > **Command Palette** and then type **build** at the prompt.

2. From the list, choose **Tasks: Run build task**.

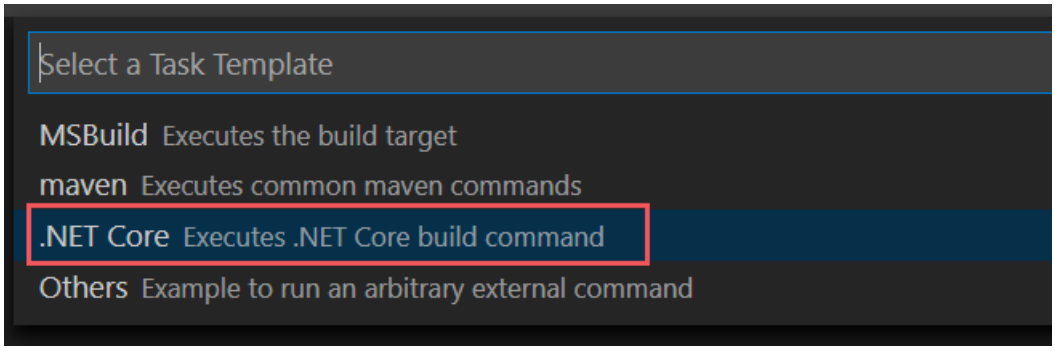
   If there are no build tasks found, select **Configure Build Task** and create one for .NET core as follows.



a. Choose **Create tasks.json from template**.



b. From the list of template types, select **.NET Core**.



c. In the build section, locate the path to the **customerkeystore.csproj** file. If it's not there, add the following line:

```
"${workspaceFolder}/src/customer-key-store/customerkeystore.csproj",
```

d. Run the build again.

3. Verify that there are no red errors in the output window.

   If there are red errors, check the console output. Ensure that you completed all the previous steps correctly and the correct build versions are present.

4. Select **Run** > **Start Debugging** to debug the process. If you're prompted to select an environment, select **.NET core**.

   The .NET core debugger typically launches to `https://localhost:5001`. To view your test key, go to `https://localhost:5001` and append a forward slash (/) and the name of your key. For example:

   ```
   https://localhost:5001/TestKey1
   ```

   The key should display in JSON format.

Your setup is now complete. Before you publish the keystore, in appsettings.json, for the JwtAudience setting, ensure the value for hostname exactly matches your App Service host name. You may have changed it to localhost to troubleshoot the build.

Deploy the DKE service and publish the key store

For production deployments, deploy the service either in a third-party cloud or publish to an on-premises system.

You may prefer other methods to deploy your keys. Select the method that works best for your organization.

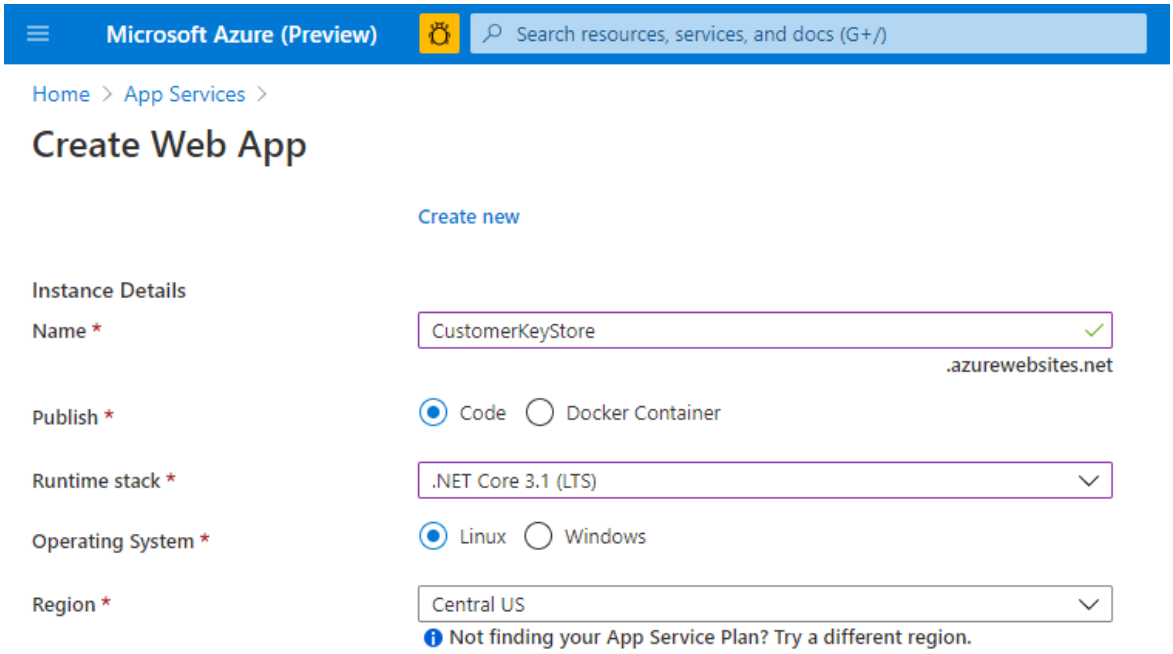
For pilot deployments, you can deploy in Azure and get started right away.

To create an Azure Web App instance to host your DKE deployment

To publish the key store, you'll create an Azure App Service instance to host your DKE deployment. Next, you'll publish your generated keys to Azure.

1. In your browser, sign in to the Microsoft Azure portal, and go to **App Services** > **Add**.
2. Select your subscription and resource group and define your instance details.
   - Enter the hostname of the computer where you want to install the DKE service. Make sure it's the same name as the one defined for the JwtAudience setting in the **appsettings.json** file. The value you provide for the name is also the WebAppInstanceName.
   - For **Publish**, select **code**, and for **Runtime stack**, select **.NET Core 3.1**.

   For example:



3. At the bottom of the page, select **Review + create**, and then select **Add**.
4. Do one of the following to publish your generated keys:
   - Publish via ZipDeployUI
   - Publish via FTP
   - Publish via Visual Studio 2019 or later

Publish via ZipDeployUI

1. Go to `https://<WebAppInstanceName>.scm.azurewebsites.net/ZipDeployUI`.

   For example: https://dkeservice.scm.azurewebsites.net/ZipDeployUI

2. In the codebase for the key store, go to the **customer-key-store\src\customer-key-store** folder, and verify that this folder contains the **customerkeystore.csproj** file.
3. Run: **dotnet publish**

   The output window displays the directory where the publish was deployed.

   For example: `customer-key-store\src\customer-key-store\bin\Debug\netcoreapp3.1\publish\`

4. Send all files in the publish directory to a .zip file. When creating the .zip file, make sure that all files in the directory are at the root level of the .zip file.

5. Drag and drop the .zip file you create to the ZipDeployUI site you opened above. For example: https://dkeservice.scm.azurewebsites.net/ZipDeployUI

DKE is deployed and you can browse to the test keys you've created. Continue to Validate your deployment below.

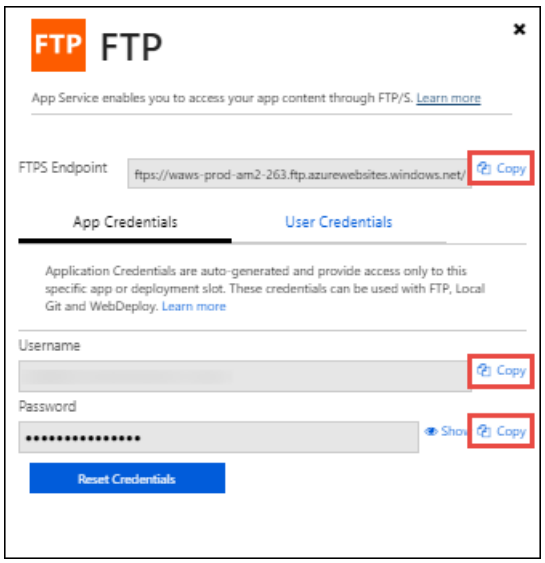
Publish via FTP

1. Connect to the App Service you created above.

   In your browser, go to: **Azure portal** > **App Service** > **Deployment Center** > **Manual Deployment** > **FTP** > **Dashboard**.

2. Copy the connection strings displayed to a local file. You'll use these strings to connect to the Web App Service and upload files via FTP.

   For example:



3. In the codebase for the key storage, go to the **customer-key-store\src\customer-key-store directory**.

4. Verify that this directory contains the **customerkeystore.csproj** file.

5. Run: **dotnet publish**

   The output contains the directory where the publish was deployed.

   For example: `customer-key-store\src\customer-key-store\bin\Debug\netcoreapp3.1\publish\`

6. Send all files in the publish directory to a zip file. When creating the .zip file, make sure that all files in the directory are at the root level of the .zip file.

7. From your FTP client, use the connection information you copied to connect to your App Service. Upload the .zip file you created in the previous step to the root directory of your Web App.

DKE is deployed and you can browse to the test keys you'd created. Next, Validate your deployment.

Validate your deployment

After deploying DKE using one of the methods described above, validate the deployment and the key store settings.

Run:

```
src\customer-key-store\scripts\key_store_tester.ps1 dkeserviceurl/mykey
```

For example:

```
key_store_tester.ps1 https://mydkeservice.com/mykey
```

Ensure that no errors appear in the output. When you're ready, register your key store.

The key name is case sensitive. Enter the key name as it appears in the appsettings.json file.

Register your key store

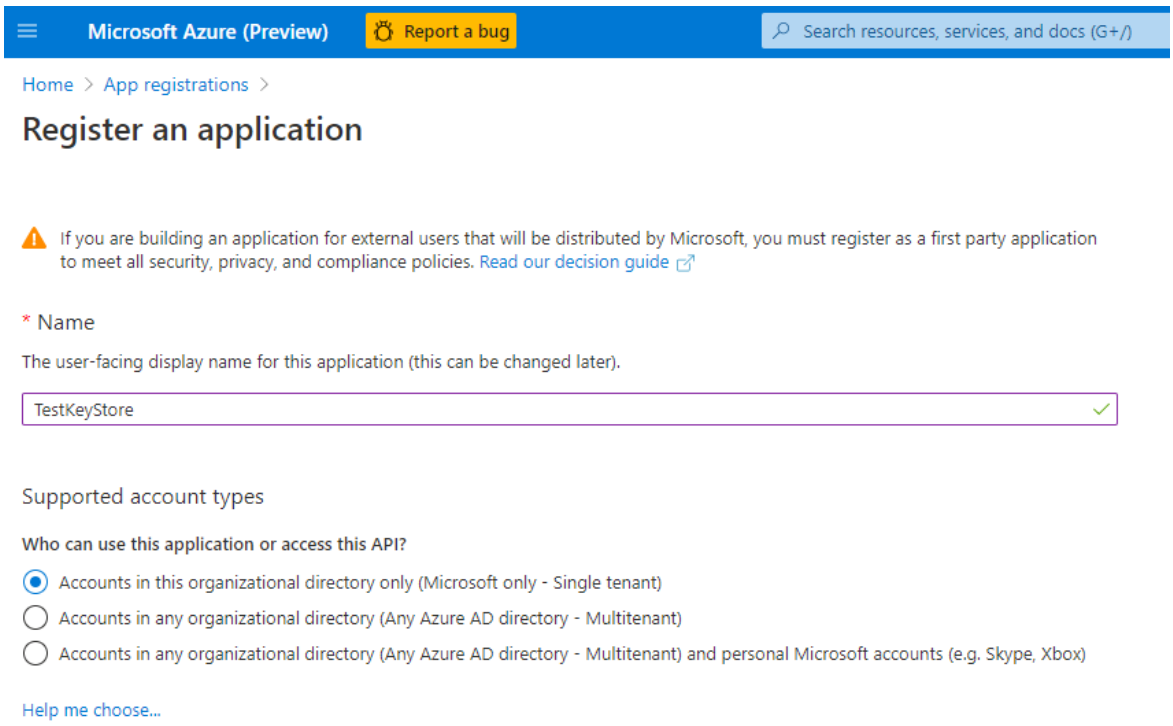
The following steps enable you to register your DKE service. Registering your DKE service is the last step in deploying DKE before you can start creating labels.

To register the DKE service:

1. In your browser, open the Microsoft Azure portal, and go to **All Services** > **Identity** > **App Registrations**.
2. Select **New registration**, and enter a meaningful name.
3. Select an account type from the options displayed.

   If you're using Microsoft Azure with a non-custom domain, such as **onmicrosoft.com**, select **Accounts in this organizational directory only (Microsoft only - Single tenant)**.

   For example:



4. At the bottom of the page, select **Register** to create the new App Registration.
5. In your new App Registration, in the left pane, under **Manage**, select **Authentication**.
6. Select **Add a platform**.
7. On the **Configure platforms** popup, select **Web**.

8. Under **Redirect URIs**, enter the URI of your double key encryption service. Enter the App Service URL, including both the hostname and domain.

   For example: https://mydkeservicetest.com

   - The URL you enter must match the hostname where your DKE service is deployed.
   - If you're testing locally with Visual Studio, use **https://localhost:5001**.
   - In all cases, the scheme must be **https**.

   Ensure the hostname exactly matches your App Service hostname. You may have changed it to `localhost` to troubleshoot the build. In **appsettings.json**, this value is the hostname you set for `JwtAudience`.

9. Under **Implicit grant**, select the **ID tokens** checkbox.
10. Select **Save** to save your changes.
11. On the left pane, select **Expose an API**, then next to Application ID URI, select **Set**.
12. Still on the **Expose an API** page, in the **Scopes defined by this API** area, select **Add a scope**. In the new scope:

    a. Define the scope name as **user_impersonation**.

    b. Select the administrators and users who can consent.

    c. Define any remaining values required.

    d. Select **Add scope**.

    e. Select **Save** at the top to save your changes.

13. Still on the **Expose an API** page, in the **Authorized client applications** area, select **Add a client application**.

    In the new client application:

    a. Define the Client ID as **d3590ed6-52b3-4102-aeff-aad2292ab01c**. This value is the Microsoft Office client ID, and enables Office to obtain an access token for your key store.

    b. Under **Authorized scopes**, select the **user_impersonation** scope.

    c. Select **Add application**.

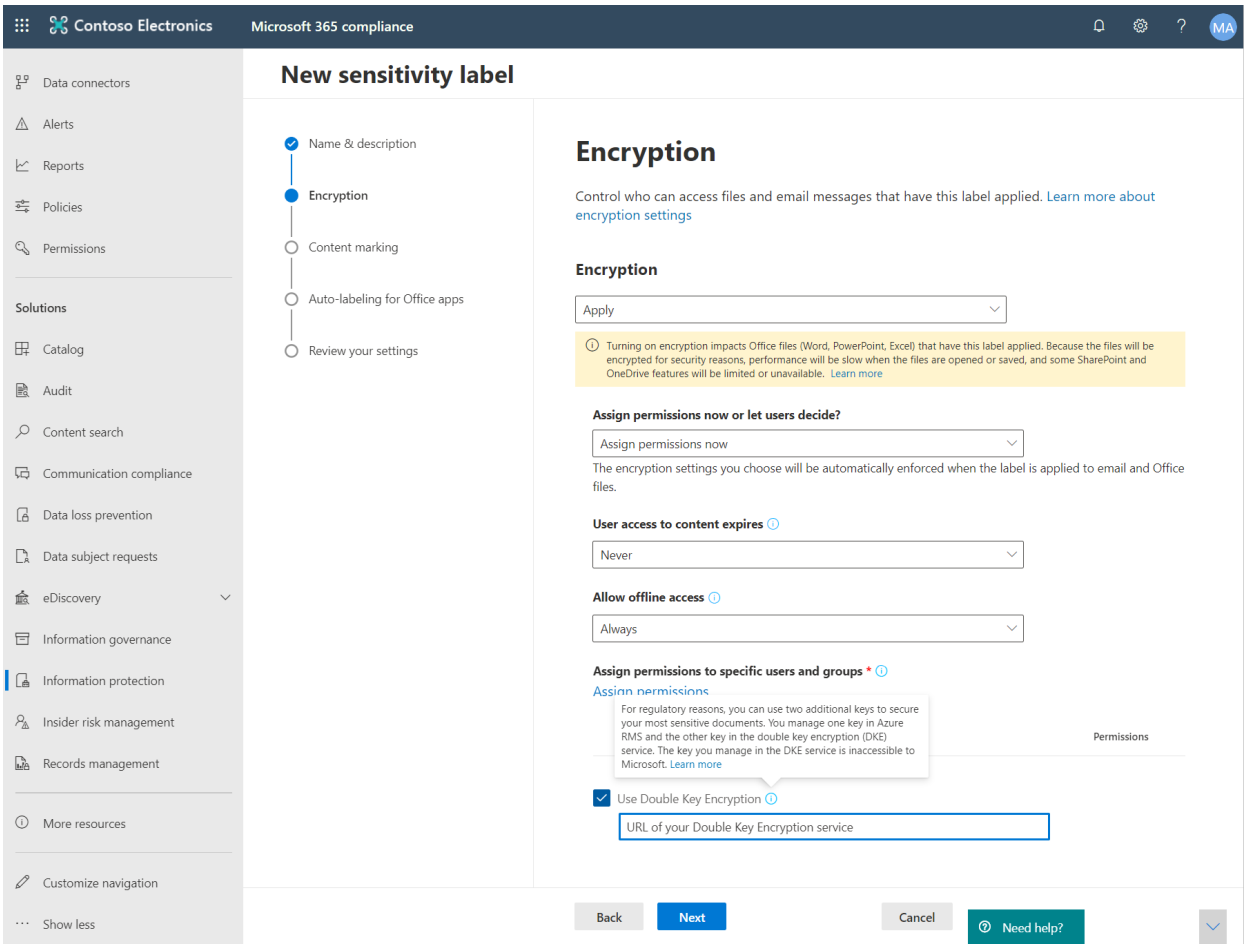
    d. Select **Save** at the top to save your changes.

Your DKE service is now registered. Continue by creating labels using DKE.

Create sensitivity labels using DKE

In the Microsoft 365 compliance center, create a new sensitivity label and apply encryption as you would otherwise. Select **Use Double Key Encryption** and enter the endpoint URL for your key.

For example:



Any DKE labels you add will start appearing for users in the latest versions of Microsoft 365 Apps for enterprise.

> **NOTE**
>
> It may take up to 24 hours for the clients to refresh with the new labels.

Enable DKE in your client

If you're an Office Insider, DKE is enabled for you. Otherwise, enable DKE for your client by adding the following registry keys:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIPC\flighting]
"DoubleKeyProtection"=dword:00000001

[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSIPC\flighting]
"DoubleKeyProtection"=dword:00000001
```

Migrate protected files from HYOK labels to DKE labels

If you want, once you're finished setting up DKE, you can migrate content that you've protected using HYOK labels to DKE labels. To migrate, you'll use the AIP scanner. To get started using the scanner, see What is the Azure Information Protection unified labeling scanner?.

If you don't migrate content, your HYOK protected content will remain unaffected.

Double Key Encryption frequently asked questions

2/18/2021 • 3 minutes to read • Edit Online

Have a question about how Double Key Encryption works? Check for an answer here.

What is Double Key Encryption for Microsoft 365 (DKE)?

Double Key Encryption for Microsoft 365 enables customers to protect their highly sensitive data to meet specialized requirements. It helps customers maintain full control of their encryption keys. It uses two keys to protect data; one key in your control and a second key stored securely in Microsoft Azure. Viewing data protected with Double Key Encryption requires access to both keys. Since Microsoft can access only one of these keys, protected data remains inaccessible to Microsoft, ensuring that you have full control over your data privacy and security.

You can host the Double Key Encryption service used to request your key, in a location of your choice (on-premises key management server or in the cloud). You maintain the service as you would any other application. Double Key Encryption enables you to control access to the Double Key Encryption service. You can store your highly sensitive data on-premises or move it to the cloud. You can be confident about preventing third-party access because you maintain full control of your key. Double Key Encryption allows you to store your data and key in the same location.

DKE helps you meet regulatory requirements across several regulations and standards such as the General Data Protection Regulation (GDPR), the Health Insurance Portability and Accountability Act (HIPAA), the Gramm-Leach-Bliley Act (GLBA), Russia's data localization law – Federal Law No. 242-FZ, Australia's Federal Privacy Act 1988, and New Zealand's Privacy Act 1993.

Can I use Double Key Encryption with Microsoft Office built-in sensitivity labeling?

You'll need to use the Azure Information Protection unified labeling client to protect documents with Double Key Encryption. Currently, you can't use Microsoft Office built-in sensitivity labeling.

What Microsoft 365 Apps can I use with DKE?

You can use DKE labels to protect documents using the desktop versions of Word, Excel, and PowerPoint on Windows. Ensure that you're using *.12711 or later (Desktop versions of Word, PowerPoint, and Excel) on Windows.

How is Double Key Encryption different from the existing hold your own key (HYOK) solution?

Double Key Encryption encrypts your data with two keys. Your encryption key is in your control and the second key is stored in Microsoft Azure, allowing you to move your encrypted data to the cloud. HYOK protects your content with only one key and the key is always on premises.

Can Double Key Encrypted documents be shared externally?

You can share Double Key Encrypted documents with users on a separate tenant as long as those users:

- Have the required permission to access your key in your Double Key Encryption service.

- Have the required permission to access your key in Microsoft Azure.

What happens to documents that are protected with HYOK?

Deploying Double Key Encryption won't affect your existing HYOK setup. However, we recommend that you start using Double Key Encryption in parallel with HYOK.

Can I run Double Key Encryption in my non-Microsoft air-gapped environment?

DKE doesn't support these environments because the service requires access to Microsoft Azure.

Where can I store Double Key Encrypted documents?

You can store Double Key Encrypted documents on-premises or in the cloud. In the cloud, you can move encrypted content to SharePoint Online and OneDrive for Business. Since Microsoft doesn't have access to your private key, the encrypted data remains opaque to Microsoft. This also means that you can't view the encrypted documents online in Office Web Apps.

What regions and languages is Double Key Encryption available in? Is Double Key Encryption available worldwide?

DKE labels are localized to the same languages as other sensitivity labels in Microsoft Information Protection. Double Key Encryption is available worldwide.

Can I convert a non-DKE label to a DKE label?

No. You can't add DKE to a label after you create it. Instead, you must choose **Use Double Key Encryption** and provide the URL of your Double Key Encryption service when you create the label.

How do I roll my DKE keys?

For instructions on rolling (also called rotating or rekeying) the key you store in Azure, see Operations for your Azure Information Protection tenant key.

See Tenant and key settings for information on creating a new key for the DKE service.

When you create a key, you set up a name and a GUID. Then, if you rotate a key, you keep the old record with the name and GUID but add a new record with the same name but different GUID. The new key gets set as active so that the public key API starts returning it for new encryption. Both keys are available for decryption so that new content and old content can be decrypted.

Service Encryption

2/18/2021 • 2 minutes to read • Edit Online

In addition to using volume-level encryption, Exchange Online, Microsoft Teams, SharePoint Online, and OneDrive for Business also use Service Encryption to encrypt customer data. Service Encryption allows for two key management options:

Microsoft-managed keys

Microsoft manages all cryptographic keys including the root keys for service encryption. This option is currently enabled by default for Exchange Online, SharePoint Online, OneDrive for Business. Microsoft-managed keys provide default service encryption unless you decide to onboard using Customer Key. If, at a later date, you decide to stop using Customer Key without following the data purge path, then your data stays encrypted using the Microsoft-managed keys. Your data is always encrypted at this default level at a minimum.

Customer Key

You supply root keys used with service encryption and you manage these keys using Azure Key Vault. Microsoft manages all other keys. This option is called Customer Key, and it is currently available for Exchange Online, SharePoint Online, and OneDrive for Business. (Previously referred to as Advanced Encryption with BYOK. See Enhancing transparency and control for Office 365 customers for the original announcement.)

Service encryption provides multiple benefits:

- Provides an added layer of protection on top of BitLocker.
- Provides separation of Windows operating system administrators from access to application data stored or processed by the operating system.
- Includes a Customer Key option that enables multi-tenant services to provide per-tenant key management.
- Enhances the ability of Microsoft 365 to meet the demands of customers that have specific compliance requirements regarding encryption.

Using Customer Key, you can generate your own cryptographic keys using either an on-premises Hardware Service Module (HSM) or Azure Key Vault (AKV). Regardless of how you generate the key, you use AKV to control and manage the cryptographic keys used by Office 365. Once your keys are stored in AKV, they can be used as the root of one of the keychains that encrypts your mailbox data or files.

Another benefit of Customer Key is the control you have over the ability of Microsoft to process your data. If you want to remove data from Office 365, such as if you want to terminate service with Microsoft or remove a portion of your data stored in the cloud, you can do so and use Customer Key as a technical control. Removing data ensures that no one, including Microsoft, can access or process the data. Customer Key is in addition and complementary to Customer Lockbox that you use to control access to your data by Microsoft personnel.

To learn how to set up Customer Key for Microsoft 365 for Exchange Online, Microsoft Teams, SharePoint Online, including Team Sites, and OneDrive for Business, see these articles:

- Service encryption with Customer Key
- Set up Customer Key
- Manage Customer Key

- Roll or rotate a customer key or an availability key
- Understand the availability key

Overview of Customer Key for Microsoft 365 at the tenant level (public preview)

2/18/2021 • 19 minutes to read • Edit Online

Using keys you provide, you can create a data encryption policy (DEP) and assign it to the tenant. The DEP encrypts data across the tenant for these workloads:

- Teams chat messages (1:1 chats, group chats, meeting chats and channel conversations)
- Teams media messages (images, code snippets, videos messages, audio messages, wiki images)
- Teams call and meeting recordings stored in Teams storage
- Teams chat notifications
- Teams chat suggestions by Cortana
- Teams status messages
- User and signal information for Exchange Online

For Microsoft Teams, Customer Key at the tenant level encrypts new data from the time the DEP is assigned to the tenant. Public preview does not support encrypting past data. For Exchange Online, Customer Key encrypts all existing and new data.

You can create multiple DEPs per tenant but can only assign one DEP at any point in time. When you assign the DEP, encryption begins automatically but can take some time to complete depending on the size of your tenant.

Tenant level policies add broader control to Customer Key for Microsoft 365

If you already have Customer Key set up for Exchange Online and Sharepoint Online, here's how the new tenant-level public preview fits in.

The tenant-level encryption policy you create encrypts all data for the Microsoft Teams and Exchange Online workloads in Microsoft 365. This policy doesn't interfere with finely tuned DEPs you've already created in Customer Key.

Examples:

Microsoft Teams files and some Teams call and meeting recordings that are saved in OneDrive for Business and SharePoint are encrypted by a SharePoint Online DEP. A single SharePoint Online DEP encrypts content within a single geo.

For Exchange Online, you can create a DEP that encrypts one or more user mailboxes with Customer Key. When you create a tenant-level policy, that policy will not encrypt the encrypted mailboxes. However, the tenant-level key will encrypt the mailboxes that are not affected by a DEP already.

Set up Customer Key at the tenant level (public preview)

These steps are similar but not identical to the steps for setting up Customer Key at the application level. You should only use this public preview with test data in test tenants. Do not use this release with production data or in your production environment. If you already have a production deployment of Customer Key, use these steps to set up Customer Key at the tenant level in a test environment.

You'll complete most of these tasks by remotely connecting to Azure PowerShell. For best results, use version

4.4.0 or later of Azure PowerShell.

Before you get started, make sure of the following:

- You'll need to use a work or school account that has the compliance admin role to set up Customer Key at the tenant level.
- Ensure that you have the appropriate licensing for your organization. Use a paid, invoiced Azure Subscription using either an Enterprise Agreement or a Cloud Service Provider. Azure Subscriptions purchased using Pay As You Go plans or using a credit card aren't supported for Customer Key. Starting April 1, 2020, Customer Key in Office 365 is offered in Office 365 E5, M365 E5, M365 E5 Compliance, and M365 E5 Information Protection & Governance SKUs. Office 365 Advanced Compliance SKU is no longer available for procuring new licenses. Existing Office 365 Advanced Compliance licenses will continue to be supported. While the service can be enabled with a minimum of one license under the tenant having the appropriate license, you should still make sure all users that benefit from the service have appropriate licenses.

Create two new Azure subscriptions

Customer Key requires two keys for each data encryption policy (DEP). To achieve this, you must create two Azure subscriptions. As a best practice, Microsoft recommends that you have separate members of your organization configure one key in each subscription. Only use these Azure subscriptions to administer encryption keys for Microsoft 365. This protects your organization in case one of your operators accidentally, intentionally, or maliciously deletes or otherwise mismanages the keys for which they are responsible.

There is no practical limit to the number of Azure subscriptions that you can create for your organization. Following this best practice helps minimize the impact of human error while helping to manage the resources used by Customer Key.

Register Azure subscriptions to use a mandatory retention period

The temporary or permanent loss of root encryption keys can be disruptive or even catastrophic to service operation and can result in data loss. For this reason, the resources used with Customer Key require strong protection. All the Azure resources that are used with Customer Key offer protection mechanisms beyond the default configuration. Azure subscriptions can be tagged or registered in a way that will prevent immediate and irrevocable cancellation. This is referred to as registering for a mandatory retention period. The steps required to register Azure subscriptions for a mandatory retention period require collaboration with the Microsoft. This process can take up to five business days. Previously, this was sometimes referred to as "Do Not Cancel".

Before contacting the Microsoft 365 team, you must perform the following steps for each Azure subscription that you use with Customer Key. Ensure that you have the Azure PowerShell Az module installed before you start.

1. Sign in with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.
2. Run the Register-AzProviderFeature cmdlet to register your subscriptions to use a mandatory retention period. Perform this action for each subscription.

   ```
   Set-AzContext -SubscriptionId <SubscriptionId>
   Register-AzProviderFeature -FeatureName mandatoryRetentionPeriodEnabled -ProviderNamespace
   Microsoft.Resources
   ```

3. Contact Microsoft to have the process finalized at m365ck@microsoft.com. Include the following in your email:

   Subject: Customer Key for < *Your tenant's fully-qualified domain name*>

   Body: Subscription IDs for which you want to have the mandatory retention period finalized. The output of Get-AzProviderFeature for each subscription.

The Service Level Agreement (SLA) for completion of this process is five business days once Microsoft has been notified (and verified) that you have registered your subscriptions to use a mandatory retention period.

4. Once you receive notification from Microsoft that registration is complete, verify the status of your registration by running the Get-AzProviderFeature command as follows. If verified, the Get-AzProviderFeature command returns a value of **Registered** for the **Registration State** property. Perform this action for each subscription.

```
Set-AzContext -SubscriptionId <SubscriptionId>
Get-AzProviderFeature -ProviderNamespace Microsoft.Resources -FeatureName
mandatoryRetentionPeriodEnabled
```

5. To complete the process, run the Register-AzResourceProvider command. Perform this action for each subscription.

```
Set-AzContext -SubscriptionId <SubscriptionId>
Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
```

Create a premium Azure Key Vault in each subscription

The steps to create a key vault are documented in Getting Started with Azure Key Vault, which guides you through installing and launching Azure PowerShell, connecting to your Azure subscription, creating a resource group, and creating a key vault in that resource group.

When you create a key vault, you must choose a SKU: either Standard or Premium. The Standard SKU allows Azure Key Vault keys to be protected with software - there is no Hardware Security Module (HSM) key protection - and the Premium SKU allows the use of HSMs for protection of Key Vault keys. Customer Key accepts key vaults that use either SKU, though Microsoft strongly recommends that you use only the Premium SKU. The cost of operations with keys of either type is the same, so the only difference in cost is the cost per month for each HSM-protected key. See Key Vault pricing for details.

> **IMPORTANT**
> Use the Premium SKU key vaults and HSM-protected keys for production data, and only use Standard SKU key vaults and keys for testing and validation purposes.

Use a common prefix for key vaults and include an abbreviation of the use and scope of the key vault and keys. For example, for the Contoso service where the vaults will be located in North America, a possible pair of names is Contoso-O365-NA-VaultA1 and Contoso-O365-NA-VaultA2. Vault names are globally unique strings within Azure, so you may need to try variations of your desired names in case the desired names are already claimed by other Azure customers. Once configured, vault names cannot be changed, so the best practice is to have a written plan for setup and use a second person to verify the plan is executed correctly.

If possible, create your vaults in non-paired regions. Paired Azure regions provide high availability across service failure domains. Therefore, regional pairs can be thought of as each other's backup region. This means that an Azure resource that is placed in one region is automatically gaining fault tolerance through the paired region. For this reason, choosing regions for two vaults used in a data encryption policy where the regions are paired means that only a total of two regions of availability are in use. Most geographies only have two regions, so it's not yet possible to select non-paired regions. If possible, choose two non-paired regions for the two vaults used with a data encryption policy. This benefits from a total of four regions of availability. For more information, see Business continuity and disaster recovery (BCDR): Azure Paired Regions for a current list of regional pairs.

Assign permissions to each key vault

For each key vault, you will need to define three separate sets of permissions for Customer Key, depending on your implementation. For example, you will need to define one set of permissions for each of the following:

- **Key vault administrators** that will perform day-to-day management of your key vault for your organization. These tasks include backup, create, get, import, list, and restore.

  > **IMPORTANT**
  > The set of permissions assigned to key vault administrators does not include the permission to delete keys. This is intentional and an important practice. Deleting encryption keys is not typically done, since doing so permanently destroys data. As a best practice, do not grant this permission to key vault administrators by default. Instead, reserve this for key vault contributors and only assign it to an administrator on a short term basis once a clear understanding of the consequences is understood.

  To assign these permissions to a user in your organization, log in to your Azure subscription with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.

  Run the Set-AzKeyVaultAccessPolicy cmdlet to assign the necessary permissions.

  ```
  Set-AzKeyVaultAccessPolicy -VaultName <vault name> -UserPrincipalName <UPN of user> -
  PermissionsToKeys create,import,list,get,backup,restore
  ```

  For example:

  ```
  Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -UserPrincipalName alice@contoso.com
  -PermissionsToKeys create,import,list,get,backup,restore
  ```

- **Key vault contributors** that can change permissions on the Azure Key Vault itself. You'll need to change these permissions as employees leave or join your team, or in the rare situation that the key vault administrators legitimately need permission to delete or restore a key. This set of key vault contributors needs to be granted the Contributor role on your key vault. You can assign this role by using Azure Resource Manager. For detailed steps, see Use Role-Based Access Control to manage access to your Azure subscription resources. The administrator who creates a subscription has this access by default, and the ability to assign other administrators to the Contributor role.

- **Microsoft 365 data at rest encryption service** that does the work of Customer Key at the tenant level. To give permission to Microsoft 365, run the **Set-AzKeyVaultAccessPolicy** cmdlet using the following syntax:

  ```
  Set-AzKeyVaultAccessPolicy -VaultName <vault name> -PermissionsToKeys wrapKey,unwrapKey,get -
  ServicePrincipalName <Microsoft 365 appID>
  ```

  Where:

  - *vault name* is the name of the key vault you created.

  Example: For the Microsoft 365 Data at Rest Encryption service, replace *Microsoft 365 appID* with `c066d759-24ae-40e7-a56f-027002b5d3e4`

  ```
  Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -PermissionsToKeys
  wrapKey,unwrapKey,get -ServicePrincipalName c066d759-24ae-40e7-a56f-027002b5d3e4
  ```

Enable and then confirm soft delete on your key vaults

When you can quickly recover your keys, you are less likely to experience an extended service outage due to

accidentally or maliciously deleted keys. Enable this configuration, referred to as Soft Delete, before you can use your keys with Customer Key. Enabling Soft Delete allows you to recover keys or vaults within 90 days of deletion without having to restore them from backup.

To enable Soft Delete on your key vaults, complete these steps:

1. Sign in to your Azure subscription with Windows PowerShell. For instructions, see Sign in with Azure PowerShell.
2. Run the Get-AzKeyVault cmdlet. In this example, *vault name* is the name of the key vault for which you are enabling soft delete:

```
$v = Get-AzKeyVault -VaultName <vault name>
$r = Get-AzResource -ResourceId $v.ResourceId
$r.Properties | Add-Member -MemberType NoteProperty -Name enableSoftDelete -Value 'True'
Set-AzResource -ResourceId $r.ResourceId -Properties $r.Properties
```

3. Confirm soft delete is configured for the key vault by running the **Get-AzKeyVault** cmdlet. If soft delete is configured properly for the key vault, then the *Soft Delete Enabled* property returns a value of **True**:

```
Get-AzKeyVault -VaultName <vault name> | fl
```

Add a key to each key vault either by creating or importing a key

There are two ways to add keys to an Azure Key Vault; you can create a key directly in Key Vault, or you can import a key. Creating a key directly in Key Vault is the less complicated method, while importing a key provides total control over how the key is generated. Use the RSA keys. Azure Key Vault doesn't support wrapping and unwrapping with elliptical curve keys.

To create a key directly in your key vault, run the Add-AzKeyVaultKey cmdlet as follows:

```
Add-AzKeyVaultKey -VaultName <vault name> -Name <key name> -Destination <HSM|Software> -KeyOps
wrapKey,unwrapKey
```

Where:

- *vault name* is the name of the key vault in which you want to create the key.
- *key name* is the name you want to give the new key.

> **TIP**
> Name keys using a similar naming convention as described above for key vaults. This way, in tools that show only the key name, the string is self-describing.

If you intend to protect the key with an HSM, ensure that you specify **HSM** as the value of the *Destination* parameter, otherwise, specify **Software**.

For example,

```
Add-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -Name Contoso-O365EX-NA-VaultA1-Key001 -Destination
HSM -KeyOps wrapKey,unwrapKey
```

Check the recovery level of your keys

Microsoft 365 requires that the Azure Key Vault subscription is set to Do Not Cancel and that the keys used by

Customer Key have soft delete enabled. You can confirm this by looking at the recovery level on your keys.

To check the recovery level of a key, in Azure PowerShell, run the Get-AzKeyVaultKey cmdlet as follows:

```
(Get-AzKeyVaultKey -VaultName <vault name> -Name <key name>).Attributes
```

If the *Recovery Level* property returns anything other than a value of **Recoverable+ProtectedSubscription**, you will need to review this article and ensure that you have followed all of the steps to put the subscription on the Do Not Cancel list and that you enabled "soft delete" on each of your key vaults. Next, send a screenshot of the output of `(Get-AzKeyVaultKey -VaultName <vault name> -Name <key name>).Attributes` in email to m365ck@microsoft.com.

Back up Azure Key Vault

Immediately following creation or any change to a key, perform a backup and store copies of the backup, both online and offline. Don't connect offline copies to any network. Instead, store them in a physical safe or commercial storage facility. At least one copy of the backup should be stored in a location that will be accessible if a disaster happens. The backup blobs are the sole means of restoring key material should a Key Vault key be permanently destroyed or otherwise rendered inoperable. Keys that are external to Azure Key Vault and were imported to Azure Key Vault do not qualify as a backup because the metadata necessary for Customer Key to use the key does not exist with the external key. Only a backup taken from Azure Key Vault can be used for restore operations with Customer Key. Therefore, it is essential that you make a backup of Azure Key Vault once a key is uploaded or created.

To create a backup of an Azure Key Vault key, run the Backup-AzKeyVaultKey cmdlet as follows:

```
Backup-AzKeyVaultKey -VaultName <vault name> -Name <key name>
-OutputFile <filename.backup>
```

Ensure that your output file uses the suffix `.backup`.

The output file resulting from this cmdlet is encrypted and cannot be used outside of Azure Key Vault. The backup can be restored only to the Azure subscription from which the backup was taken.

For example:

```
Backup-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -Name Contoso-O365EX-NA-VaultA1-Key001 -OutputFile
Contoso-O365EX-NA-VaultA1-Key001-Backup-20170802.backup
```

Validate Azure Key Vault configuration settings

Performing validation before using keys in a DEP is optional, but highly recommended. In particular, if you use steps to set up your keys and vaults other than the ones described in this topic, you should validate the health of your Azure Key Vault resources before you configure Customer Key.

To verify that your keys have get, wrapKey, and unwrapKey operations enabled:

Run the Get-AzKeyVault cmdlet as follows:

```
Get-AzKeyVault -VaultName <vault name>
```

In the output, look for the Access Policy and for the Microsoft 365 app ID (GUID) as appropriate. All three operations, get, wrapKey, and unwrapKey, must be shown under Permissions to Keys.

If the access policy configuration is incorrect, run the Set-AzKeyVaultAccessPolicy cmdlet as follows:

```
Set-AzKeyVaultAccessPolicy -VaultName <vault name> -PermissionsToKeys wrapKey,unwrapKey,get -
ServicePrincipalName <Microsoft 365 appID>
```

Example: For the Microsoft 365 Data at Rest Encryption service, replace *Microsoft 365 appID* with `c066d759-24ae-40e7-a56f-027002b5d3e4`

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -PermissionsToKeys wrapKey,unwrapKey,get -
ServicePrincipalName c066d759-24ae-40e7-a56f-027002b5d3e4
```

To verify that an expiration date is not set for your keys, run the Get-AzKeyVaultKey cmdlet as follows:

```
Get-AzKeyVaultKey -VaultName <vault name>
```

An expired key cannot be used by Customer Key and operations attempted with an expired key will fail and possibly result in a service outage. We strongly recommend that keys used with Customer Key do not have an expiration date. An expiration date, once set, cannot be removed, but can be changed to a different date. If a key must be used that has an expiration date set, change the expiration value to 12/31/9999. Keys with an expiration date set to a date other than 12/31/9999 will not pass Microsoft 365 validation.

To change an expiration date that has been set to any value other than 12/31/9999, run the Update-AzKeyVaultKey cmdlet as follows:

```
Update-AzKeyVaultKey -VaultName <vault name> -Name <key name> -Expires (Get-Date -Date "12/31/9999")
```

Obtain the URI for each Azure Key Vault key

Once you've completed all the steps in Azure to set up your key vaults and added your keys, run the following command to get the URI for the key in each key vault. You will need to use these URIs when you create and assign each DEP later, so save this information in a safe place. Remember to run this command once for each key vault.

In Azure PowerShell:

```
(Get-AzKeyVaultKey -VaultName <vault name>).Id
```

Set up the Customer Key encryption policy for your tenant

You need to be assigned permissions before you can run these cmdlets. Although this article lists all parameters for the cmdlets, you may not have access to some parameters if they're not included in the permissions assigned to you. To find the permissions required to run any cmdlet or parameter in your organization, see Find the permissions required to run any Exchange cmdlet.

Create policy

```
   New-M365DataAtRestEncryptionPolicy [-Name] <String> -AzureKeyIDs <MultiValuedProperty> [-Description
<String>] [-Enabled <Boolean>]
```

Description: Enable compliance admin to create a new data encryption policy (DEP) using two AKV root keys. Once created, a policy can then be assigned using Set-M365DataAtRestEncryptionPolicy cmdlet. Upon first assignment of keys or after you rotate keys, it can take up to 24 hours for the new keys to take effect. If the new DEP takes more than 24 hours to take effect, contact Microsoft.

Example:

```
New-M365DataAtRestEncryptionPolicy -Name "Default_Policy" -AzureKeyIDs
"https://contosoWestUSvault01.vault.azure.net/keys/Key_01","https://contosoEastUSvault01.vault.azure.net/key
s/Key_02" -Description "Tenant default policy"
```

Parameters:

NAME	DESCRIPTION	OPTIONAL (Y/N)
Name	Friendly name of the data encryption policy	N
AzureKeyIDs	Specifies two URI values of the Azure Key Vault keys, separated by a comma, to associate with the data encryption policy	N
Description	Description of the data encryption policy	N

Assign policy

```
Set-M365DataAtRestEncryptionPolicyAssignment -Policy “<Default_PolicyName or Default_PolicyID>”
```

Description: This cmdlet is used for configuring default Data Encryption Policy. This policy will be used to then encrypt data across all support workloads.

Example:

```
Set-M365DataAtRestEncryptionPolicyAssignment -Policy “Tenant default policy”
```

Parameters: | Name | Description | Optional (Y/N) | |----------|----------|---------| -Policy|Specifies the data encryption policy that needs to be assigned; specify either the Policy Name or the Policy ID.|N|

Modify or Refresh policy

```
Set-M365DataAtRestEncryptionPolicy [-Identity] < M365DataAtRestEncryptionPolicy
DataEncryptionPolicyIdParameter> -Refresh [-Enabled <Boolean>] [-Name <String>] [-Description <String>]
```

Description: The cmdlet can be used either to modify or refresh an existing policy. It can also be used to enable or disable a policy. Upon first assignment of keys or after you rotate keys, it can take up to 24 hours for the new keys to take effect. If the new DEP takes more than 24 hours to take effect, contact Microsoft.

Examples:

Disable a data encryption policy.

```
Set-M365DataAtRestEncryptionPolicy -Identity "NAM Policy" -Enabled $false
```

Refresh a data encryption policy.

```
Set-M365DataAtRestEncryptionPolicy -Identity “EUR Policy” -Refresh
```

Parameters: | Name | Description | Optional (Y/N) | |----------|----------|---------| |-Identity|Specifies the data encryption policy that you want to modify.|N| |-Refresh|Use the Refresh switch to update the data encryption policy after you rotate any of the associated keys in the Azure Key Vault. You don't need to specify a value with this switch.|Y| |-Enabled|The Enabled parameter enables or disable the data encryption policy. Before you disable a policy, you must unassign it from your tenant. Valid values are:
$true: The policy is enabled
$false: The policy is disabled.|Y| |-Name|The Name parameter specifies the unique name for the data encryption policy.|Y |-Description|The Description parameter specifies an optional description for the data encryption policy.|Y|

Get policy details

```
Get-M365DataAtRestEncryptionPolicy [-Identity] < M365DataAtRestEncryptionPolicy
DataEncryptionPolicyIdParameter>
```

Description: This cmdlet lists all of M365DataAtRest encryption policies that are created for the tenant or details about a specific policy.

Examples:

This example returns a summary list of M365DatAtRest Encryption policies in the organization.

```
Get-M365DataAtRestEncryptionPolicy
```

This example returns detailed information for the data encryption policy named "NAM Policy".

```
Get-M365DataAtRestEncryptionPolicy -Identity "NAM Policy"
```

Parameters:

NAME	DESCRIPTION	OPTIONAL (Y/N)
-Identity	Specifies the data encryption policy that you want to list the details for.	Y

Get policy assignment info

```
Get-M365DataAtRestEncryptionPolicyAssignment
```

Description: This cmdlet lists the policy that’s currently assigned to the tenant.

Offboarding from Customer Key

If you need to revert back to Microsoft-managed keys, you can. When you offboard, your data is re-encrypted using default encryption supported by each individual workload. For example, Exchange Online supports default encryption using Microsoft-managed keys.

If you decided to offboard your tenant from Customer Key at the tenant level, reach out to Microsoft with a request through email to “disable” the service for the tenant at m365ck@microsoft.com.

IMPORTANT

Offboarding is not the same as a data purge. A data purge permanently crypto-deletes your organization's data from Microsoft 365, offboarding does not. You can't perform a data purge for a tenant-level policy. For information about data purge path, see Revoke your keys and start the data purge path process.

About the availability key

For information about the availability key, see Learn about the availability key.

Key rotation

For information about rotating or rolling keys used with Customer Key, see Roll or rotate a Customer Key or an availability key. When you update the DEP to use the new version of the keys, you'll run the Set-M365DataAtRestEncryptionPolicy cmdlet as described earlier in this article.

Service encryption with Customer Key

2/18/2021 • 4 minutes to read • Edit Online

Microsoft 365 provides baseline, volume-level encryption enabled through BitLocker and Distributed Key Manager (DKM). Microsoft 365 offers an added layer of encryption at the application layer for your content. This content includes data from Exchange Online, Skype for Business,
SharePoint Online, OneDrive for Business, and Teams files. This added layer of encryption is called service encryption.

How service encryption, BitLocker, and Customer Key work together

Service encryption ensures that content at rest is encrypted at the service layer. **Your data is always encrypted at rest in the Microsoft 365 service with BitLocker and DKM**. For more information, see the "Security, Privacy, and Compliance Information", and How Exchange Online secures your email secrets.
Customer Key provides additional protection against viewing of data by unauthorized systems or personnel, and complements BitLocker disk encryption in Microsoft datacenters. Service encryption is not meant to prevent Microsoft personnel from accessing customer data. The primary purpose is to assist customers in meeting regulatory or compliance obligations for controlling root keys. Customers explicitly authorize O365 services to use their encryption keys to provide value added cloud services, such as eDiscovery, anti-malware, anti-spam, search indexing, etc.

Customer Key is built on service encryption and lets you provide and control encryption keys. Microsoft 365 then uses these keys to encrypt your data at rest as described in the Online Services Terms (OST). Customer Key helps you meet compliance obligations because you control the encryption keys that Microsoft 365 uses to encrypt and decrypt data.

Customer Key enhances the ability of your organization to meet the demands of compliance requirements that specify key arrangements with the cloud service provider. With Customer Key, you provide and control the root encryption keys for your Microsoft 365 data at-rest at the application level. As a result, you exercise control over your organization's keys. If you decide to exit the service, you revoke access to your organization's root keys. For all Microsoft 365 services, revoking access to the keys is the first step on the path towards data deletion. By revoking access to the keys, the data is unreadable to the service.

Customer Key encrypts data at rest in Office 365

Using keys you provide, Customer Key encrypts:

- SharePoint Online, OneDrive for Business, and Teams files.
- Files uploaded to OneDrive for Business.
- Exchange Online mailbox content including e-mail body content, calendar entries, and the content within email attachments.
- Text conversations from Skype for Business.

We don't currently offer customer control of the encryption keys for Skype Meeting Broadcast and Skype Meeting content uploads. Instead, this content is encrypted along with all other content in Office 365.

Customer Key with hybrid deployments

Customer Key only encrypts data at rest in the cloud. Customer Key does not work to protect your on-premises mailboxes and files. You can encrypt your on-premises data using another method, such as BitLocker.

About the data encryption policy (DEP)

A data encryption policy defines the encryption hierarchy to encrypt data using each of the keys you provide as well as the availability key protected by Microsoft. You create DEPs using PowerShell cmdlets, which are different for each service, and assign those DEPs to encrypt application data. For example:

Exchange Online and Skype for Business You can create up to 50 DEPs per tenant. You associate DEPs to your Customer Keys in Azure Key Vault and then assign DEPs to individual mailboxes. When you assign a DEP to a mailbox:

- the mailbox is marked for a mailbox move. Based on priorities in Microsoft 365 as described here Move requests in the Microsoft 365 service.
- The encryption takes place while the mailbox is moved. Allow 72 hours for the mailbox to become encrypted with the new DEP. If the mailboxes aren't encrypted after waiting 72 hours from the time you assigned the DEP, contact Microsoft.

Later, you can either refresh the DEP or assign a different DEP to the mailbox as described in Manage Customer Key for Office 365. Each mailbox must have appropriate licenses in order to assign a DEP. For more information about licensing, see Before you set up Customer Key.

> **NOTE**
> The DEP can be applied to a shared mailbox, public folder mailbox, and Microsoft 365 group mailbox for tenants that meet the licensing requirement for user mailboxes, even though some of these mailbox types cannot be an assigned license (public folder mailbox and Microsoft 365 group mailbox) or need a license for increasing storage (shared mailbox).

SharePoint Online, OneDrive for Business, and Teams files If you're using the multi-geo feature, you can create up to one DEP per geo for your organization. You can use different Customer Keys for each geo. If you're not using the multi-geo feature, you can only create one DEP per tenant. When you assign the DEP, encryption begins automatically but can take some time to complete. Refer to the details in Set up Customer Key.

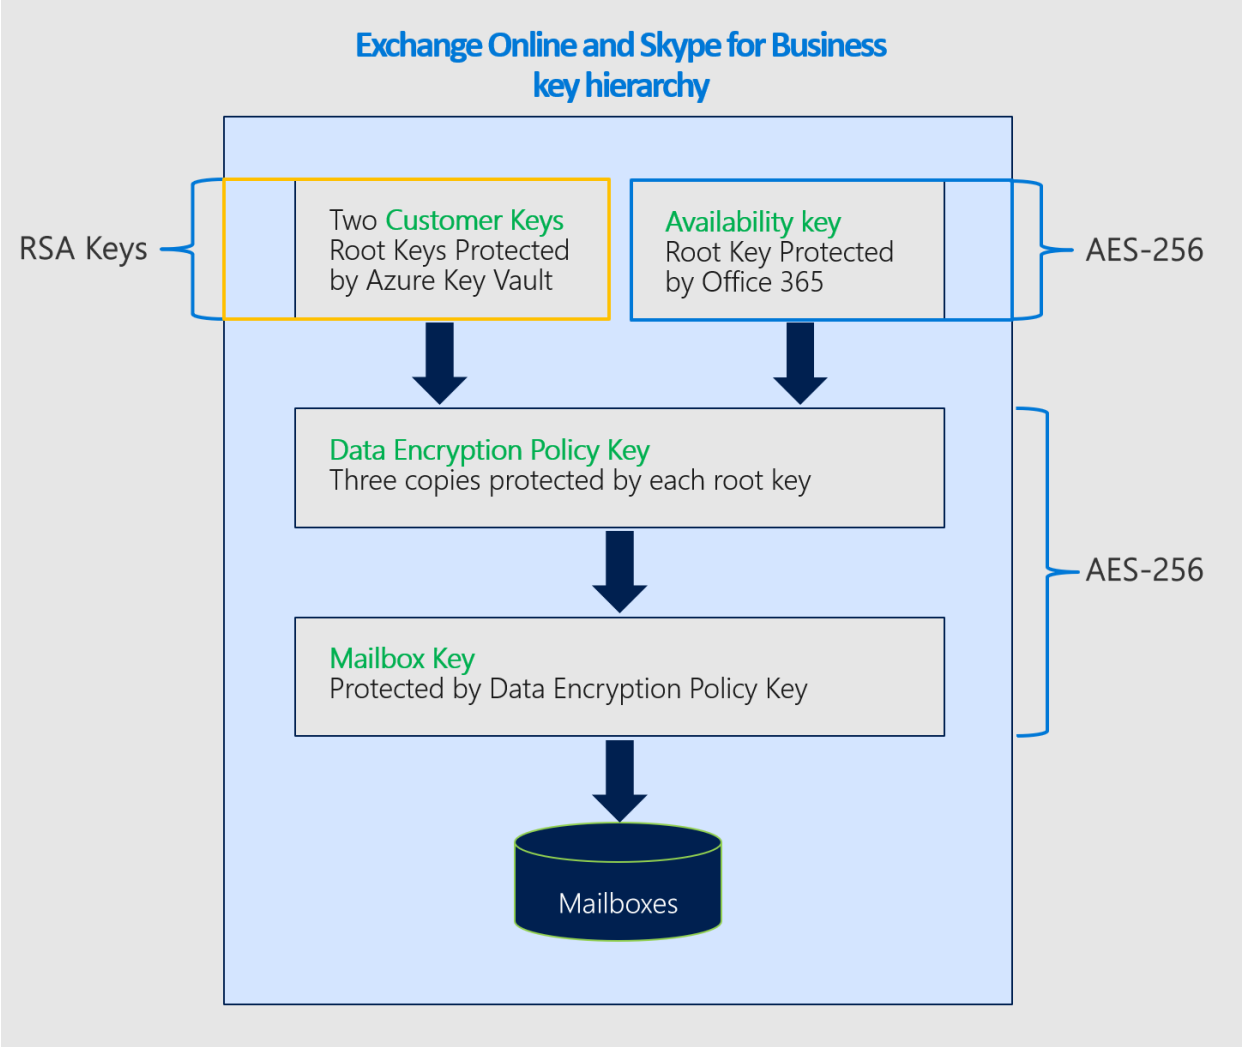
Leaving the service

Customer Key assists you in meeting compliance obligations by allowing you to revoke your keys when you leave the Microsoft 365 service. When you revoke your keys as part of leaving the service, the availability key is deleted resulting in cryptographic deletion of your data. Cryptographic deletion mitigates the risk of data remanence which is important for meeting both security and compliance obligations. For information about the data purge process and key revocation, see Revoke your keys and start the data purge path process.

Encryption ciphers used by Customer Key

Customer Key uses a variety of encryption ciphers to encrypt keys as shown in the following figures.

Encryption ciphers used to encrypt keys for Exchange Online and Skype for Business



Encryption ciphers used to encrypt keys for SharePoint Online, OneDrive for Business, and Teams files

Set up Customer Key at the application level

2/18/2021 • 26 minutes to read • Edit Online

With Customer Key, you control your organization's encryption keys and then configure Microsoft 365 to use them to encrypt your data at rest in Microsoft's data centers. In other words, Customer Key allows customers to add a layer of encryption that belongs to them, with their keys. Data at rest includes data from Exchange Online and Skype for Business that is stored in mailboxes and files that are stored in SharePoint Online and OneDrive for Business.

You must set up Azure before you can use Customer Key for Office 365. This article describes the steps you need to follow to create and configure the required Azure resources and then provides the steps for setting up Customer Key in Office 365. After you have completed Azure setup, you determine which policy, and therefore, which keys, to assign to mailboxes and files in your organization. Mailboxes and files for which you don't assign a policy will use encryption policies that are controlled and managed by Microsoft. For more information about Customer Key, or for a general overview, see Service encryption with Customer Key in Office 365.

IMPORTANT

We strongly recommend that you follow the best practices in this article. These are called out as **TIP** and **IMPORTANT**. Customer Key gives you control over root encryption keys whose scope can be as large as your entire organization. This means that mistakes made with these keys can have a broad impact and may result in service interruptions or irrevocable loss of your data.

Before you set up Customer Key

Before you get started, ensure that you have the appropriate licensing for your organization. Use a paid, invoiced Azure Subscription using either an Enterprise Agreement or a Cloud Service Provider. Azure Subscriptions purchased using Pay As You Go plans or using a credit card aren't supported for Customer Key. Starting April 1, 2020, Customer Key in Office 365 is offered in Office 365 E5, M365 E5, M365 E5 Compliance, and M365 E5 Information Protection & Governance SKUs. Office 365 Advanced Compliance SKU is no longer available for procuring new licenses. Existing Office 365 Advanced Compliance licenses will continue to be supported.

To understand the concepts and procedures in this article, review the Azure Key Vault documentation. Also, become familiar with the terms used in Azure, for example, Azure AD tenant.

FastTrack is only used to collect the required tenant and service configuration information used to register for Customer Key. The Customer Key Offers are published via FastTrack so that it is convenient for you and our partners to submit the required information using the same method. FastTrack also makes it easy to archive the data that you provide in the Offer.

If you need more support beyond the documentation, contact Microsoft Consulting Services (MCS), Premier Field Engineering (PFE), or a Microsoft partner for assistance. To provide feedback on Customer Key, including the documentation, send your ideas, suggestions, and perspectives to customerkeyfeedback@microsoft.com.

Overview of steps to set up Customer Key

To set up Customer Key, complete these tasks in the listed order. The rest of this article provides detailed instructions for each task, or links out to more information for each step in the process.

In Azure and Microsoft FastTrack:

You will complete most of these tasks by remotely connecting to Azure PowerShell. For best results, use version 4.4.0 or later of Azure PowerShell.

- Create two new Azure subscriptions
- Register Azure subscriptions to use a mandatory retention period

  Registration can take from one to five business days.
- Submit a request to activate Customer Key for Office 365

Once you've created the two new Azure subscriptions, you'll need to submit the appropriate Customer Key offer request by completing a web form that is hosted in the Microsoft FastTrack portal. **The FastTrack team doesn't provide assistance with Customer Key. Office simply uses the FastTrack portal to allow you to submit the form and to help us track the relevant offers for Customer Key**.

- Create a premium Azure Key Vault in each subscription
- Assign permissions to each key vault
- Enable and then confirm soft delete on your key vaults
- Add a key to each key vault either by creating or importing a key
- Check the recovery level of your keys
- Back up Azure Key Vault
- Validate Azure Key Vault configuration settings
- Obtain the URI for each Azure Key Vault key

In Office 365:

Exchange Online and Skype for Business:

- Create a data encryption policy (DEP) for use with Exchange Online and Skype for Business
- Assign a DEP to a mailbox
- Validate mailbox encryption

SharePoint Online and OneDrive for Business:

- Create a data encryption policy (DEP) for each SharePoint Online and OneDrive for Business geo
- Validate file encryption for SharePoint Online, OneDrive for Business, and Teams files

Complete tasks in Azure Key Vault and Microsoft FastTrack for Customer Key

Complete these tasks in Azure Key Vault. You'll need to complete these steps regardless of whether you intend to set up Customer Key for Exchange Online and Skype for Business or for SharePoint Online, OneDrive for Business, and Teams files, or for all supported services in Office 365.

Create two new Azure subscriptions

Customer Key requires two Azure subscriptions. As a best practice, Microsoft recommends that you create new Azure subscriptions for use with Customer Key. Azure Key Vault keys can only be authorized for applications in the same Azure Active Directory (Microsoft Azure Active Directory) tenant, you must create the new subscriptions using the same Azure AD tenant used with your organization where the DEPs will be assigned. For example, using your work or school account that has global administrator privileges in your organization. For

detailed steps, see Sign up for Azure as an organization.

> **IMPORTANT**
> Customer Key requires two keys for each data encryption policy (DEP). In order to achieve this, you must create two Azure subscriptions. As a best practice, Microsoft recommends that you have separate members of your organization configure one key in each subscription. You should only use these Azure subscriptions to administer encryption keys for Office 365. This protects your organization in case one of your operators accidentally, intentionally, or maliciously deletes or otherwise mismanages the keys for which they are responsible.

There is no practical limit to the number of Azure subscriptions that you can create for your organization. Following these best practices will minimize the impact of human error while helping to manage the resources used by Customer Key.

Submit a request to activate Customer Key for Office 365

Once you've completed the Azure steps, you'll need to submit an offer request in the Microsoft FastTrack portal. Once you've submitted a request through the FastTrack web portal, Microsoft verifies the Azure Key Vault configuration data and contact information you provided. The selections that you make in the offer form about the authorized officers of your organization is critical and necessary for completion of Customer Key registration. The officers of your organization ensure the authenticity of any request to revoke and destroy all keys used with a Customer Key data encryption policy. You'll need to do this step once to activate Customer Key for Exchange Online and Skype for Business coverage and a second time to activate Customer Key for SharePoint Online and OneDrive for Business.

To submit an offer to activate Customer Key, complete these steps:

1. Using a work or school account that has global administrator permissions in your organization, sign in to the Microsoft FastTrack portal.
2. Once you're logged in, browse to the **Dashboard**.
3. Choose **Deploy** from the navigation bar **OR** select **View all deployment resources** on the **Deploy** information card, and review the list of current offers.
4. Choose the information card for the offer that applies to you:
   - **Exchange Online and Skype for Business:** Choose the **Request encryption key help for Exchange online** offer.
   - **SharePoint Online, OneDrive, and Teams files:** Choose the **Request encryption key help for Sharepoint and OneDrive** offer.
5. Once you've reviewed the offer details, choose **Continue to step 2**.
6. Fill out all applicable details and requested information on the offer form. Pay particular attention to your selections for which officers of your organization you want to authorize to approve the permanent and irreversible destruction of encryption keys and data. Once you've completed the form, choose **Submit**.

Register Azure subscriptions to use a mandatory retention period

The temporary or permanent loss of root encryption keys can be disruptive or even catastrophic to service operation and can result in data loss. For this reason, the resources used with Customer Key require strong protection. All the Azure resources that are used with Customer Key offer protection mechanisms beyond the default configuration. You can tag or register Azure subscriptions for a *mandatory retention period*. A mandatory retention period prevents immediate and irrevocable cancellation of your Azure subscription. The steps required to register Azure subscriptions for a mandatory retention period require collaboration with the Microsoft 365 team. This process can take from one to five business days. Previously, mandatory retention period was sometimes referred to as "Do Not Cancel".

Before contacting the Microsoft 365 team, you must do the following steps for each Azure subscription that you use with Customer Key. Ensure that you have the Azure PowerShell Az module installed before you start.

1. Sign in with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.
2. Run the Register-AzProviderFeature cmdlet to register your subscriptions to use a mandatory retention period. Complete this action for each subscription.

   ```
   Set-AzContext -SubscriptionId <SubscriptionId>
   Register-AzProviderFeature -FeatureName mandatoryRetentionPeriodEnabled -ProviderNamespace
   Microsoft.Resources
   ```

3. Contact Microsoft to complete the process. For the SharePoint and OneDrive for Business team, contact spock@microsoft.com. For Exchange Online and Skype for Business, contact exock@microsoft.com. Include the following information in your email:

   Subject: Customer Key for *< Your tenant's fully qualified domain name>*

   Body: Include the subscription IDs for which you want to complete the mandatory retention period and the output of Get-AzProviderFeature for each subscription.

   The Service Level Agreement (SLA) for completion of this process is five business days once Microsoft has been notified (and verified) that you have registered your subscriptions to use a mandatory retention period.

4. Once you receive notification from Microsoft that registration is complete, verify the status of your registration by running the Get-AzProviderFeature command as follows. If verified, the Get-AzProviderFeature command returns a value of **Registered** for the **Registration State** property. Complete this step for each subscription.

   ```
   Set-AzContext -SubscriptionId <SubscriptionId>
   Get-AzProviderFeature -ProviderNamespace Microsoft.Resources -FeatureName
   mandatoryRetentionPeriodEnabled
   ```

5. To complete the process, run the Register-AzResourceProvider command. Complete this step for each subscription.

   ```
   Set-AzContext -SubscriptionId <SubscriptionId>
   Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
   ```

Create a premium Azure Key Vault in each subscription

The steps to create a key vault are documented in Getting Started with Azure Key Vault, which guides you through installing and launching Azure PowerShell, connecting to your Azure subscription, creating a resource group, and creating a key vault in that resource group.

When you create a key vault, you must choose a SKU: either Standard or Premium. The Standard SKU allows Azure Key Vault keys to be protected with software - there's no Hardware Security Module (HSM) key protection - and the Premium SKU allows the use of HSMs for protection of Key Vault keys. Customer Key accepts key vaults that use either SKU, though Microsoft strongly recommends that you use only the Premium SKU. The cost of operations with keys of either type is the same, so the only difference in cost is the cost per month for each HSM-protected key. See Key Vault pricing for details.

> **IMPORTANT**
>
> Use the Premium SKU key vaults and HSM-protected keys for production data, and only use Standard SKU key vaults and keys for testing and validation purposes.

For each Microsoft 365 service with which you will use Customer Key, create a key vault in each of the two Azure subscriptions that you created. For example, for Exchange Online and Skype for Business only or SharePoint Online and OneDrive for Business only, you'll create only one pair of vaults. To enable Customer Key for both Exchange Online and SharePoint Online, you will create two pairs of key vaults.

Use a naming convention for key vaults that reflects the intended use of the DEP with which you will associate the vaults. See the Best Practices section below for naming convention recommendations.

Create a separate, paired set of vaults for each data encryption policy. For Exchange Online, the scope of a data encryption policy is chosen by you when you assign the policy to mailbox. A mailbox can have only one policy assigned, and you can create up to 50 policies. The scope of a SharePoint Online policy includes all of the data within an organization in a geographic location, or *geo*.

The creation of key vaults also requires the creation of Azure resource groups, since key vaults need storage capacity (though small) and Key Vault logging, if enabled, also generates stored data. As a best practice Microsoft recommends using separate administrators to manage each resource group, with the administration that's aligned with the set of administrators that will manage all related Customer Key resources.

> **IMPORTANT**
>
> To maximize availability, your key vaults should be in regions close to your Microsoft 365 service. For example, if your Exchange Online organization is in North America, place your key vaults in North America. If your Exchange Online organization is in Europe, place your key vaults in Europe.
>
> Use a common prefix for key vaults, and include an abbreviation of the use and scope of the key vault and keys (e.g., for the Contoso SharePoint service where the vaults will be located in North America, a possible pair of names is Contoso-O365SP-NA-VaultA1 and Contoso-O365SP-NA-VaultA2. Vault names are globally unique strings within Azure, so you may need to try variations of your desired names in case the desired names are already claimed by other Azure customers. As of July 2017 vault names cannot be changed, so a best practice is to have a written plan for setup and use a second person to verify the plan is executed correctly.
>
> If possible, create your vaults in non-paired regions. Paired Azure regions provide high availability across service failure domains. Therefore, regional pairs can be thought of as each other's backup region. This means that an Azure resource that is placed in one region is automatically gaining fault tolerance through the paired region. For this reason, choosing regions for two vaults used in a data encryption policy where the regions are paired means that only a total of two regions of availability are in use. Most geographies only have two regions, so it's not yet possible to select non-paired regions. If possible, choose two non-paired regions for the two vaults used with a data encryption policy. This benefits from a total of four regions of availability. For more information, see Business continuity and disaster recovery (BCDR): Azure Paired Regions for a current list of regional pairs.

Assign permissions to each key vault

You'll need to define three separate sets of permissions for each key vault, depending on your implementation. For example, you will need to define one set of permissions for each of the following:

- **Key vault administrators** that do day-to-day management of your key vault for your organization. These tasks include backup, create, get, import, list, and restore.

> **IMPORTANT**
> The set of permissions assigned to key vault administrators does not include the permission to delete keys. This is intentional and an important practice. Deleting encryption keys is not typically done, since doing so permanently destroys data. As a best practice, do not grant this permission to key vault administrators by default. Instead, reserve this for key vault contributors and only assign it to an administrator on a short term basis once a clear understanding of the consequences is understood.

To assign these permissions to a user in your organization, sign in to your Azure subscription with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.

- Run the Set-AzKeyVaultAccessPolicy cmdlet to assign the necessary permissions.

```
Set-AzKeyVaultAccessPolicy -VaultName <vault name> -UserPrincipalName <UPN of user> -
PermissionsToKeys create,import,list,get,backup,restore
```

For example:

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -UserPrincipalName alice@contoso.com
-PermissionsToKeys create,import,list,get,backup,restore
```

- **Key vault contributors** that can change permissions on the Azure Key Vault itself. You'll need to change these permissions as employees leave or join your team. In the rare situation that the key vault administrators legitimately need permission to delete or restore a key you'll also need to change the permissions. This set of key vault contributors needs to be granted the **Contributor** role on your key vault. You can assign this role by using Azure Resource Manager. For detailed steps, see Use Role-Based Access Control to manage access to your Azure subscription resources. The administrator who creates a subscription has this access implicitly, and the ability to assign other administrators to the Contributor role.

- If you intend to use Customer Key with Exchange Online and Skype for Business, you need to give permission to Microsoft 365 to use the key vault on behalf of Exchange Online and Skype for Business. Likewise, if you intend to use Customer Key with SharePoint Online and OneDrive for Business, you need to add permission for the Microsoft 365 to use the key vault on behalf of SharePoint Online and OneDrive for Business. To give permission to Microsoft 365, run the **Set-AzKeyVaultAccessPolicy** cmdlet using the following syntax:

```
Set-AzKeyVaultAccessPolicy -VaultName <vault name> -PermissionsToKeys wrapKey,unwrapKey,get -
ServicePrincipalName <Office 365 appID>
```

Where:

  - *vault name* is the name of the key vault you created.
  - For Exchange Online and Skype for Business, replace *Office 365 appID* with `00000002-0000-0ff1-ce00-000000000000`
  - For SharePoint Online, OneDrive for Business, and Teams files, replace *Office 365 appID* with `00000003-0000-0ff1-ce00-000000000000`

Example: Setting permissions for Exchange Online and Skype for Business:

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -PermissionsToKeys
wrapKey,unwrapKey,get -ServicePrincipalName 00000002-0000-0ff1-ce00-000000000000
```

Example: Setting permissions for SharePoint Online, OneDrive for Business, and Teams files:

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365SP-NA-VaultA1 -PermissionsToKeys
wrapKey,unwrapKey,get -ServicePrincipalName 00000003-0000-0ff1-ce00-000000000000
```

Enable and then confirm soft delete on your key vaults

When you can quickly recover your keys, you are less likely to experience an extended service outage due to accidentally or maliciously deleted keys. You need to enable this configuration, referred to as Soft Delete, before you can use your keys with Customer Key. Enabling Soft Delete allows you to recover keys or vaults within 90 days of deletion without having to restore them from backup.

To enable Soft Delete on your key vaults, complete these steps:

1. Sign in to your Azure subscription with Windows PowerShell. For instructions, see Sign in with Azure PowerShell.
2. Run the Get-AzKeyVault cmdlet. In this example, *vault name* is the name of the key vault for which you are enabling soft delete:

```
$v = Get-AzKeyVault -VaultName <vault name>
$r = Get-AzResource -ResourceId $v.ResourceId
$r.Properties | Add-Member -MemberType NoteProperty -Name enableSoftDelete -Value 'True'
Set-AzResource -ResourceId $r.ResourceId -Properties $r.Properties
```

3. Confirm soft delete is configured for the key vault by running the **Get-AzKeyVault** cmdlet. If soft delete is configured properly for the key vault, then the *Soft Delete Enabled* property returns a value of **True**:

```
Get-AzKeyVault -VaultName <vault name> | fl
```

Add a key to each key vault either by creating or importing a key

There are two ways to add keys to an Azure Key Vault; you can create a key directly in Key Vault, or you can import a key. Creating a key directly in Key Vault is the less complicated method, while importing a key provides total control over how the key is generated. Use the RSA keys. Azure Key Vault doesn't support wrapping and unwrapping with elliptical curve keys.

To create a key directly in your key vault, run the Add-AzKeyVaultKey cmdlet as follows:

```
Add-AzKeyVaultKey -VaultName <vault name> -Name <key name> -Destination <HSM|Software> -KeyOps
wrapKey,unwrapKey
```

Where:

- *vault name* is the name of the key vault in which you want to create the key.
- *key name* is the name you want to give the new key.

> **TIP**
> Name keys using a similar naming convention as described above for key vaults. This way, in tools that show only the key name, the string is self-describing.

If you intend to protect the key with an HSM, ensure that you specify **HSM** as the value of the *Destination* parameter, otherwise, specify **Software**.

For example,

```
Add-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -Name Contoso-O365EX-NA-VaultA1-Key001 -Destination
HSM -KeyOps wrapKey,unwrapKey
```

To import a key directly into your key vault, you need to have a nCipher nShield Hardware Security Module.

Some organizations prefer this approach to establish the provenance of their keys, and then this method also provides the following attestations:

- The toolset used for import includes attestation from nCipher that the Key Exchange Key (KEK) that is used to encrypt the key you generate is not exportable and is generated inside a genuine HSM that was manufactured by nCipher.
- The toolset includes attestation from nCipher that the Azure Key Vault security world was also generated on a genuine HSM manufactured by nCipher. This attestation proves to you that Microsoft is also using genuine nCipher hardware.

Check with your security group to determine if the above attestations are required. For detailed steps to create a key on-premises and import it into your key vault, see How to generate and transfer HSM-protected keys for Azure Key Vault. Use the Azure instructions to create a key in each key vault.

Check the recovery level of your keys

Microsoft 365 requires that the Azure Key Vault subscription is set to Do Not Cancel and that the keys used by Customer Key have soft delete enabled. You can confirm you subscriptions settings by looking at the recovery level on your keys.

To check the recovery level of a key, in Azure PowerShell, run the Get-AzKeyVaultKey cmdlet as follows:

```
(Get-AzKeyVaultKey -VaultName <vault name> -Name <key name>).Attributes
```

If the *Recovery Level* property returns anything other than a value of **Recoverable+ProtectedSubscription**, ensure that you have put the subscription on the Do Not Cancel list and that you have soft delete enabled on each of your key vaults.

Back up Azure Key Vault

Immediately following creation or any change to a key, perform a backup and store copies of the backup, both online and offline. Offline copies should not be connected to any network, such as in a physical safe or commercial storage facility. At least one copy of the backup should be stored in a location that will be accessible in the event of a disaster. The backup blobs are the sole means of restoring key material should a Key Vault key be permanently destroyed or otherwise rendered inoperable. Keys that are external to Azure Key Vault and were imported to Azure Key Vault do not qualify as a backup because the metadata necessary for Customer Key to use the key does not exist with the external key. Only a backup taken from Azure Key Vault can be used for restore operations with Customer Key. Therefore, you must create a backup of Azure Key Vault after you upload or create a key.

To create a backup of an Azure Key Vault key, run the Backup-AzKeyVaultKey cmdlet as follows:

```
Backup-AzKeyVaultKey -VaultName <vault name> -Name <key name>
-OutputFile <filename.backup>
```

Ensure that your output file uses the suffix `.backup`.

The output file resulting from this cmdlet is encrypted and cannot be used outside of Azure Key Vault. The backup can be restored only to the Azure subscription from which the backup was taken.

> **TIP**
> For the output file, choose a combination of your vault name and key name. This will make the file name self-describing. It will also ensure that backup file names do not collide.

For example:

```
Backup-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -Name Contoso-O365EX-NA-VaultA1-Key001 -OutputFile
Contoso-O365EX-NA-VaultA1-Key001-Backup-20170802.backup
```

Validate Azure Key Vault configuration settings

Validating before using keys in a DEP is optional, but highly recommended. If you use steps to set up your keys and vaults other than the ones described in this article, validate the health of your Azure Key Vault resources before you configure Customer Key.

To verify that your keys have `get`, `wrapKey`, and `unwrapKey` operations enabled:

Run the Get-AzKeyVault cmdlet as follows:

```
Get-AzKeyVault -VaultName <vault name>
```

In the output, look for the Access Policy and for the Exchange Online identity (GUID) or the SharePoint Online identity (GUID) as appropriate. All three of the above permissions must be shown under Permissions to Keys.

If the access policy configuration is incorrect, run the Set-AzKeyVaultAccessPolicy cmdlet as follows:

```
Set-AzKeyVaultAccessPolicy -VaultName <vault name> -PermissionsToKeys wrapKey,unwrapKey,get -
ServicePrincipalName <Office 365 appID>
```

For example, for Exchange Online and Skype for Business:

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1
-PermissionsToKeys wrapKey,unwrapKey,get -ServicePrincipalName 00000002-0000-0ff1-ce00-000000000000
```

For example, for SharePoint Online and OneDrive for Business:

```
Set-AzKeyVaultAccessPolicy -VaultName Contoso-O365SP-NA-VaultA1
-PermissionsToKeys wrapKey,unwrapKey,get -ServicePrincipalName 00000003-0000-0ff1-ce00-000000000000
```

To verify that an expiration date isn't set for your keys, run the Get-AzKeyVaultKey cmdlet as follows:

```
Get-AzKeyVaultKey -VaultName <vault name>
```

Customer Key can't use an expired key. Operations attempted with an expired key will fail, and possibly result in a service outage. We strongly recommend that keys used with Customer Key do not have an expiration date. An expiration date, once set, cannot be removed, but can be changed to a different date. If a key must be used that has an expiration date set, change the expiration value to 12/31/9999. Keys with an expiration date set to a date other than 12/31/9999 will not pass Microsoft 365 validation.

To change an expiration date that has been set to any value other than 12/31/9999, run the Update-AzKeyVaultKey cmdlet as follows:

```
Update-AzKeyVaultKey -VaultName <vault name> -Name <key name> -Expires (Get-Date -Date "12/31/9999")
```

Caution

Don't set expiration dates on encryption keys you use with Customer Key.

Obtain the URI for each Azure Key Vault key

Once you've set up your key vaults and added your keys, run the following command to get the URI for the key in each key vault. You'll need to use these URIs when you create and assign each DEP later, so save this information in a safe place. Run this command once for each key vault.

In Azure PowerShell:

```
(Get-AzKeyVaultKey -VaultName <vault name>).Id
```

Office 365: Setting up Customer Key for Exchange Online and Skype for Business

Before you begin, ensure that you've completed the tasks required to set up Azure Key Vault. See Complete tasks in Azure Key Vault and Microsoft FastTrack for Customer Key for information.

To set up Customer Key for Exchange Online and Skype for Business, you'll complete these steps by remotely connecting to Exchange Online with Windows PowerShell.

Create a data encryption policy (DEP) for use with Exchange Online and Skype for Business

A DEP is associated with a set of keys stored in Azure Key Vault. You assign a DEP to a mailbox in Microsoft 365. Microsoft 365 will then use the keys identified in the policy to encrypt the mailbox. To create the DEP, you need the Key Vault URIs you obtained earlier. See Obtain the URI for each Azure Key Vault key for instructions.

Remember! When you create a DEP, you specify two keys in two different Azure Key Vaults. Create these keys in two separate Azure regions to ensure geo-redundancy.

To create the DEP, follow these steps:

1. On your local computer, using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell in a Windows PowerShell window.
2. To create a DEP, use the New-DataEncryptionPolicy cmdlet by typing the following command.

   ```
   New-DataEncryptionPolicy -Name <PolicyName> -Description "Policy Description" -AzureKeyIDs
   <KeyVaultURI1>, <KeyVaultURI2>
   ```

   Where:

   - *PolicyName* is the name you want to use for the policy. Names can't contain spaces. For example, USA_mailboxes.
   - *Policy Description* is a user-friendly description of the policy that will help you remember what the policy is for. You can include spaces in the description. For example, "Root key for mailboxes in USA and its territories".
   - *KeyVaultURI1* is the URI for the first key in the policy. For example, https://contoso_EastUSvault01.vault.azure.net/keys/USA_key_01.

- *KeyVaultURI2* is the URI for the second key in the policy. For example, https://contoso_EastUS2vault01.vault.azure.net/keys/USA_Key_02. Separate the two URIs by a comma and a space.

Example:

```
New-DataEncryptionPolicy -Name USA_mailboxes -Description "Root key for mailboxes in USA and its territories" -AzureKeyIDs https://contoso_EastUSvault01.vault.azure.net/keys/USA_key_01, https://contoso_EastUS2vault01.vault.azure.net/keys/USA_Key_02
```

For detailed syntax and parameter information, see New-DataEncryptionPolicy.

Assign a DEP to a mailbox

Assign the DEP to a mailbox by using the Set-Mailbox cmdlet. Once you assign the policy, Microsoft 365 can encrypt the mailbox with the key identified in the DEP.

```
Set-Mailbox -Identity <MailboxIdParameter> -DataEncryptionPolicy <PolicyName>
```

Where *MailboxIdParameter* specifies a user mailbox. For more information about the Set-Mailbox cmdlet, see Set-Mailbox.

In hybrid environments, you can assign a DEP to the on-premises mailbox data that is synchronized into your Exchange Online tenant. To assign a DEP to this synchronized mailbox data, you'll use the Set-MailUser cmdlet. For more information about mailbox data in the hybrid environment, see on-premises mailboxes using Outlook for iOS and Android with hybrid Modern Authentication.

```
Set-MailUser -Identity <MailUserIdParameter> -DataEncryptionPolicy <PolicyName>
```

Where *MailUserIdParameter* specifies a mail user (also known as a mail-enabled user). For more information about the Set-MailUser cmdlet, see Set-MailUser.

Validate mailbox encryption

Encrypting a mailbox can take some time. For first-time policy assignment, the mailbox must also completely move from one database to another before the service can encrypt the mailbox. We recommend that you wait 72 hours before you attempt to validate encryption after you change a DEP or the first time you assign a DEP to a mailbox.

Use the Get-MailboxStatistics cmdlet to determine if a mailbox is encrypted.

```
Get-MailboxStatistics -Identity <GeneralMailboxOrMailUserIdParameter> | fl IsEncrypted
```

The IsEncrypted property returns a value of **true** if the mailbox is encrypted and a value of **false** if the mailbox isn't encrypted. The time to complete mailbox moves depends on the number of mailboxes to which you assign a DEP for the first time, and the size of the mailboxes. If the mailboxes haven't been encrypted after a week from the time you assigned the DEP, contact Microsoft.

Office 365: Setting up Customer Key for SharePoint Online, OneDrive for Business, and Teams files

Before you begin, ensure that you've completed the tasks required to set up Azure Key Vault. See Complete tasks in Azure Key Vault and Microsoft FastTrack for Customer Key for information.

To set up Customer Key for SharePoint Online, OneDrive for Business, and Teams files you complete these steps

by remotely connecting to SharePoint Online with Windows PowerShell.

Create a data encryption policy (DEP) for each SharePoint Online and OneDrive for Business geo

You associate a DEP with a set of keys stored in Azure Key Vault. You apply a DEP to all of your data in one geographic location, also called a geo. If you use the multi-geo feature of Office 365, you can create one DEP per geo with the capability to use different keys per geo. If you aren't using multi-geo, you can create one DEP in your organization for use with SharePoint Online, OneDrive for Business, and Teams files. Microsoft 365 uses the keys identified in the DEP to encrypt your data in that geo. To create the DEP, you need the Key Vault URIs you obtained earlier. See Obtain the URI for each Azure Key Vault key for instructions.

Remember! When you create a DEP, you specify two keys in two different Azure Key Vaults. Create these keys in two separate Azure regions to ensure geo-redundancy.

To create a DEP, you need to remotely connect to SharePoint Online by using Windows PowerShell.

1. On your local computer, using a work or school account that has global administrator permissions in your organization, Connect to SharePoint Online PowerShell.
2. In the Microsoft SharePoint Online Management Shell, run the Register-SPODataEncryptionPolicy cmdlet as follows:

   ```
   Register-SPODataEncryptionPolicy -Identity <adminSiteCollectionURL> -PrimaryKeyVaultName
   <PrimaryKeyVaultName> -PrimaryKeyName <PrimaryKeyName> -PrimaryKeyVersion <PrimaryKeyVersion> -
   SecondaryKeyVaultName <SecondaryKeyVaultName> -SecondaryKeyName <SecondaryKeyName> -
   SecondaryKeyVersion <SecondaryKeyVersion>
   ```

   Example:

   ```
   Register-SPODataEncryptionPolicy -Identity https://contoso.sharepoint.com -PrimaryKeyVaultName
   'stageRG3vault' -PrimaryKeyName 'SPKey3' -PrimaryKeyVersion 'f635a23bd4a44b9996ff6aadd88d42ba' -
   SecondaryKeyVaultName 'stageRG5vault' -SecondaryKeyName 'SPKey5' -SecondaryKeyVersion
   '2b3e8f1d754f438dacdec1f0945f251a’
   ```

   When you register the DEP, encryption begins on the data in the geo. Encryption can take some time. For more information on using this parameter, see Register-SPODataEncryptionPolicy.

Validate file encryption

To validate encryption of SharePoint Online, OneDrive for Business, and Teams files, connect to SharePoint Online PowerShell, and then use the Get-SPODataEncryptionPolicy cmdlet to check the status of your tenant. The *State* property returns a value of **registered** if Customer Key encryption is enabled and all files in all sites have been encrypted. If encryption is still in progress, this cmdlet returns a value of **registering**.

Manage Customer Key

11/2/2020 • 9 minutes to read • Edit Online

After you've set up Customer Key for Office 365, you can manage your keys as described in this article. Learn more about Customer Key in the related topics.

Restore Azure Key Vault keys

Before performing a restore, use the recovery capabilities provided by soft delete. All keys that are used with Customer Key are required to have soft delete enabled. Soft delete acts like a recycle bin and allows recovery for up to 90 days without the need to restore. Restore should only be required in extreme or unusual circumstances, for example if the key or key vault is lost. If you must restore a key for use with Customer Key, in Azure PowerShell, run the Restore-AzureKeyVaultKey cmdlet as follows:

```
Restore-AzKeyVaultKey -VaultName <vault name> -InputFile <filename>
```

For example:

```
Restore-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -InputFile Contoso-O365EX-NA-VaultA1-Key001-
Backup-20170802.backup
```

If the key vault already contains a key with the same name, the restore operation fails. Restore-AzKeyVaultKey restores all key versions and all metadata for the key including the key name.

Manage key vault permissions

Several cmdlets are available that enable you to view and, if necessary, remove key vault permissions. You might need to remove permissions, for example, when an employee leaves the team. For each of these tasks, you will use Azure PowerShell. For information about Azure Powershell, see Overview of Azure PowerShell.

To view key vault permissions, run the Get-AzKeyVault cmdlet.

```
Get-AzKeyVault -VaultName <vault name>
```

For example:

```
Get-AzKeyVault -VaultName Contoso-O365EX-NA-VaultA1
```

To remove an administrator's permissions, run the Remove-AzKeyVaultAccessPolicy cmdlet:

```
Remove-AzKeyVaultAccessPolicy -VaultName <vault name> -UserPrincipalName <UPN of user>
```

For example:

```
Remove-AzKeyVaultAccessPolicy -VaultName Contoso-O365EX-NA-VaultA1 -UserPrincipalName alice@contoso.com
```

Manage data encryption policies (DEPs) with Customer Key

Customer Key handles DEPs differently between the different services. For example, you can create a different number of DEPs for the different services.

Exchange Online and Skype for Business: You can create up to 50 DEPs. For instructions, see Create a data encryption policy (DEP) for use with Exchange Online and Skype for Business.

SharePoint Online, OneDrive for Business, and Teams files: A DEP applies to data in one geographic location, also called a *geo*. If you use the multi-geo feature of Office 365, you can create one DEP per geo. If you are not using multi-geo, you can create one DEP. Normally, you create the DEP when you set up Customer Key. For instructions, see Create a data encryption policy (DEP) for each SharePoint Online and OneDrive for Business geo.

View the DEPs you've created for Exchange Online and Skype for Business

To view a list of all the DEPs you've created for Exchange Online and Skype for Business using the Get-DataEncryptionPolicy PowerShell cmdlet, complete these steps.

1. Using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell.
2. To return all DEPs in your organization, run the Get-DataEncryptionPolicy cmdlet without any parameters.

   ```
   Get-DataEncryptionPolicy
   ```

   For more information about the Get-DataEncryptionPolicy cmdlet, see Get-DataEncryptionPolicy.

Assign a DEP before you migrate a mailbox to the cloud

When you assign the DEP, Microsoft 365 encrypts the contents of the mailbox using the assigned DEP during the migration. This process is more efficient than migrating the mailbox, assigning the DEP, and then waiting for encryption to take place, which can take hours or possibly days.

To assign a DEP to a mailbox before you migrate it to Office 365, run the Set-MailUser cmdlet in Exchange Online PowerShell:

1. Using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell.
2. Run the Set-MailUser cmdlet.

   ```
   Set-MailUser -Identity <GeneralMailboxOrMailUserIdParameter> -DataEncryptionPolicy
   <DataEncryptionPolicyIdParameter>
   ```

   Where *GeneralMailboxOrMailUserIdParameter* specifies a mailbox, and *DataEncryptionPolicyIdParameter* is the ID of the DEP. For more information about the Set-MailUser cmdlet, see Set-MailUser.

Determine the DEP assigned to a mailbox

To determine the DEP assigned to a mailbox, use the Get-MailboxStatistics cmdlet. The cmdlet returns a unique identifier (GUID).

1. Using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell.

   ```
   Get-MailboxStatistics -Identity <GeneralMailboxOrMailUserIdParameter> | fl DataEncryptionPolicyID
   ```

Where *GeneralMailboxOrMailUserIdParameter* specifies a mailbox and DataEncryptionPolicyID returns the GUID of the DEP. For more information about the Get-MailboxStatistics cmdlet, see Get-MailboxStatistics.

2. Run the Get-DataEncryptionPolicy cmdlet to find out the friendly name of the DEP to which the mailbox is assigned.

```
Get-DataEncryptionPolicy <GUID>
```

Where *GUID* is the GUID returned by the Get-MailboxStatistics cmdlet in the previous step.

Verify that Customer Key has finished encryption

Whether you've just rolled a Customer Key, assigned a new DEP, or migrated a mailbox, use the steps in this section to ensure that encryption completes.

Verify encryption completes for Exchange Online and Skype for Business

Encrypting a mailbox can take some time. We recommend that you wait 72 hours before you attempt to validate encryption after you change a DEP or the first time you assign a DEP to a mailbox.

Use the Get-MailboxStatistics cmdlet to determine if a mailbox is encrypted.

```
Get-MailboxStatistics -Identity <GeneralMailboxOrMailUserIdParameter> | fl IsEncrypted
```

The IsEncrypted property returns a value of **true** if the mailbox is encrypted and a value of **false** if the mailbox is not encrypted.

The time to complete mailbox moves depends on the size of the mailbox. If Customer Key hasn't completely encrypted the mailbox after 72 hours from the time you assign a new DEP, contact Microsoft support for help. The New-MoveRequest cmdlet is no longer available for local mailbox moves. Refer to this announcement for additional information.

Verify encryption completes for SharePoint Online, OneDrive for Business, and Teams files

Check on the status of encryption by running the Get-SPODataEncryptionPolicy cmdlet as follows:

```
Get-SPODataEncryptionPolicy -Identity <SPOAdminSiteUrl>
```

The output from this cmdlet includes:

- The URI of the primary key.
- The URI of the secondary key.
- The encryption status for the geo. Possible states include:
  - **Unregistered:** Customer Key encryption has not yet been applied.
  - **Registering:** Customer Key encryption has been applied and your files are in the process of being encrypted. If the key for the geo is registering, you'll also be shown information on what percentage of sites in the geo are complete so that you can monitor encryption progress.
  - **Registered:** Customer Key encryption has been applied, and all files in all sites have been encrypted.
  - **Rolling:** A key roll is in progress. If the key for the geo is rolling, you'll also be shown information on what percentage of sites have completed the key roll operation so that you can monitor

progress.

Unassign a DEP from a mailbox

You unassign a DEP from a mailbox using the Set-mailbox PowerShell cmdlet and setting the `DataEncryptionPolicy` to `$NULL`. Running this cmdlet unassigns the currently assigned DEP and reencrypts the mailbox using the DEP associated with default Microsoft managed keys. You can't unassign the DEP used by Microsoft managed keys. If you don't want to use Microsoft managed keys, you can assign another DEP to the mailbox.

To unassign the DEP from a mailbox using the Set-Mailbox PowerShell cmdlet, complete these steps.

1. Using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell.
2. Run the Set-Mailbox cmdlet.

```
Set-Mailbox -Identity <mailbox> -DataEncryptionPolicy $NULL
```

Revoke your keys and start the data purge path process

You control the revocation of all root keys including the availability key. Customer Key provides control of the exit planning aspect of the regulatory requirements for you. If you decide to revoke your keys to purge your data and exit the service, the service deletes the availability key once the data purge process completes.

Microsoft 365 audits and validates the data purge path. For more information, see the SSAE 18 SOC 2 Report available on the Service Trust Portal. In addition, Microsoft recommends the following documents:

- Risk Assessment and Compliance Guide for Financial Institutions in the Microsoft Cloud
- O365 Exit Planning Considerations

The data purge path differs slightly between the different services.

Revoke your Customer Keys and the availability key for Exchange Online and Skype for Business

When you initiate the data purge path for Exchange Online and Skype for Business, you set a permanent data purge request on a DEP. Doing so permanently deletes encrypted data within the mailboxes to which that DEP is assigned.

Since you can only run the PowerShell cmdlet against one DEP at a time, consider reassigning a single DEP to all of your mailboxes before you initiate the data purge path.

> **WARNING**
> Do not use the data purge path to delete a subset of your mailboxes. This process is only intended for customers who are exiting the service.

To initiate the data purge path, complete these steps:

1. Remove wrap and unwrap permissions for "O365 Exchange Online" from Azure Key Vaults.
2. Using a work or school account that has global administrator privileges in your organization, connect to Exchange Online PowerShell.
3. For each DEP that contains mailboxes that you want to delete, run the Set-DataEncryptionPolicy cmdlet as follows.

```
Set-DataEncryptionPolicy <Policy ID> -PermanentDataPurgeRequested -PermanentDataPurgeReason <Reason>
-PermanentDataPurgeContact <ContactName>
```

If the command fails, ensure that you've removed the Exchange Online permissions from both keys in Azure Key Vault as specified earlier in this task.Once you've set the PermanentDataPurgeRequested switch using the Set-DataEncryptionPolicy cmdlet, you'll no longer be able to assign this DEP to mailboxes.

4. Contact Microsoft support and request the Data Purge eDocument.

   At your request, Microsoft sends you a legal document to acknowledge and authorize data deletion. The person in your organization who signed up as an approver in the FastTrack offer during onboarding needs to sign this document. Normally, this is an executive or other designated person in your company who is legally authorized to sign the paperwork on behalf of your organization.

5. Once your representative has signed the legal document, return it to Microsoft (usually through an eDoc signature).

   Once Microsoft receives the legal document, Microsoft runs cmdlets to trigger the data purge which first deletes the policy, marks the mailboxes for permanent deletion, then deletes the availability key. Once the data purge process completes, the data has been purged, is inaccessible to Exchange Online, and is not recoverable.

Revoke your Customer Keys and the availability key for SharePoint Online, OneDrive for Business, and Teams files

To initiate the data purge path for SharePoint Online, OneDrive for Business, and Teams files, complete these steps:

1. Revoke Azure Key Vault access. All key vault admins must agree to revoke access.

   You do not delete the Azure Key Vault for SharePoint Online. Key vaults may be shared among several SharePoint Online tenants and DEPs.

2. Contact Microsoft to delete the availability key.

   When you contact Microsoft to delete the availability key, we'll send you a legal document. The person in your organization who signed up as an approver in the FastTrack offer during onboarding needs to sign this document. Normally, this is an executive or other designated person in your company who's legally authorized to sign the paperwork on behalf of your organization.

3. Once your representative signs the legal document, return it to Microsoft (usually through an eDoc signature).

   Once Microsoft receives the legal document, we run cmdlets to trigger the data purge which performs crypto deletion of the tenant key, site key, and all individual per-document keys, irrevocably breaking the key hierarchy. Once the data purge cmdlets complete, your data has been purged.

Roll or rotate a Customer Key or an availability key

4/21/2020 • 4 minutes to read • Edit Online

Caution

Only roll an encryption key that you use with Customer Key when your security or compliance requirements dictate that you must roll the key. In addition, do not delete any keys that are or were associated with policies. When you roll your keys, there will be content encrypted with the previous keys. For example, while active mailboxes will be re-encrypted frequently, inactive, disconnected, and disabled mailboxes may still be encrypted with the previous keys. SharePoint Online performs backup of content for restore and recovery purposes, so there may still be archived content using older keys.

About rolling the availability key

Microsoft does not expose direct control of the availability key to customers. For example, you can only roll (rotate) the keys that you own in Azure Key Vault. Microsoft 365 rolls the availability keys on an internally-defined schedule. There is no customer-facing, service-level agreement (SLA) for these key rolls. Microsoft 365 rotates the availability key using Microsoft 365 service code in an automated, non-manual process. Microsoft administrators may initiate the roll process. The key is rolled using automated mechanisms without direct access to the key store. Access to the availability key secret store is not provisioned to Microsoft administrators. Availability key rolling leverages the same mechanism used to initially generate the key. For more information about the availability key, see Understand the availability key.

IMPORTANT

Exchange Online and Skype for Business availability keys can be effectively rolled by customers creating a new DEP, since a unique availability key is generated for each DEP you create. Availability keys for SharePoint Online, OneDrive for Business, and Teams files exist at the forest level and are shared across DEPs and customers, which means rolling only occurs at a Microsoft internally defined schedule. To mitigate the risk of not rolling the availability key each time a new DEP is created, SharePoint, OneDrive, and Teams roll the tenant intermediate key (TIK), the key wrapped by the customer root keys and availability key, each time a new DEP is created.

Request a new version of each existing root key you want to roll

When you roll a key, you request a new version of an existing key. To request a new version of an existing key, you use the same cmdlet, Add-AzKeyVaultKey, with the same syntax that you used to create the key in the first place. After you've finished rolling any key associated with a Data Encryption Policy (DEP), you run another cmdlet to ensure that Customer Key begins using the new key. Do this step in each Azure Key Vault (AKV).

For example:

1. Sign in to your Azure subscription with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.
2. Run the Add-AzKeyVaultKey cmdlet as shown in the following example:

```
Add-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -Name Contoso-O365EX-NA-VaultA1-Key001 -
Destination HSM -KeyOps @('wrapKey','unwrapKey') -NotBefore (Get-Date -Date "12/27/2016 12:01 AM")
```

In this example, since a key named **Contoso-O365EX-NA-VaultA1-Key001** exists in the **Contoso-O365EX-NA-VaultA1** vault, the cmdlet creates a new version of the key. This operation preserves the

previous key versions in the version history for the key. You need the previous key version to decrypt the data that it still encrypts. Once you complete rolling any key associated with a DEP, run an extra cmdlet to ensure that Customer Key begins using the new key. The following sections describe the cmdlets in more detail.

Update the Customer Key for Exchange Online and Skype for Business

When you roll either of the Azure Key Vault keys associated with a DEP used with Exchange Online and Skype for Business, you must update the DEP to point to the new key. This does not rotate the availability key.

To instruct Customer Key to use the new key to encrypt mailboxes, run the Set-DataEncryptionPolicy cmdlet as follows:

1. Run the Set-DataEncryptionPolicy cmdlet in Azure PowerShell:

   ```
   Set-DataEncryptionPolicy -Identity <DataEncryptionPolicyID> -Refresh
   ```

   Within 72 hours, the active mailboxes associated with this DEP become encrypted with the new key.

2. To check the value for the DataEncryptionPolicyID property for the mailbox, use the steps in Determine the DEP assigned to a mailbox. The value for this property changes once the service applies the updated key.

Update the Customer Key for SharePoint Online, OneDrive for Business, and Teams files

SharePoint Online only allows you to roll one key at a time. If you want to roll both keys in a key vault, wait for the first operation to complete. Microsoft recommends that you stagger your operations to avoid this issue. When you roll either of the Azure Key Vault keys associated with a DEP used with SharePoint Online and OneDrive for Business, you must update the DEP to point to the new key. This does not rotate the availability key.

1. Run the Update-SPODataEncryptionPolicy cmdlet as follows:

   ```
   Update-SPODataEncryptionPolicy -Identity <SPOAdminSiteUrl> -KeyVaultName <ReplacementKeyVaultName> -
   KeyName <ReplacementKeyName> -KeyVersion <ReplacementKeyVersion> -KeyType <Primary | Secondary>
   ```

   While this cmdlet starts the key roll operation for SharePoint Online and OneDrive for Business, the action doesn't complete immediately.

2. To see the progress of the key roll operation, run the Get-SPODataEncryptionPolicy cmdlet as follows:

   ```
   Get-SPODataEncryptionPolicy -Identity <SPOAdminSiteUrl>
   ```

Learn about the availability key for Customer Key

4/21/2020 • 15 minutes to read • Edit Online

The availability key is a root key automatically generated and provisioned when you create a data encryption policy. Microsoft 365 stores and protects the availability key. The availability key is functionally like the two root keys that you supply for service encryption with Customer Key. The availability key wraps the keys one tier lower in the key hierarchy. Unlike the keys that you provide and manage in Azure Key Vault, you can't directly access the availability key. Microsoft 365 automated services manage the availability key programatically. These services initiate automated operations that never involve direct access to the availability key.

The primary purpose of the availability key is to provide recovery capability from the unanticipated loss of root keys that you manage. Loss could be a result of mismanagement or malicious action. If you lose control of your root keys, contact Microsoft Support and Microsoft will assist you through the process of recovery using the availability key. You'll use the availability key to migrate to a new Data Encryption Policy with new root keys you provision.

Storage and control of the availability key are deliberately different from Azure Key Vault keys for three reasons:

- The availability key provides a recovery, "break-glass" capability if control over both Azure Key Vault keys is lost.
- The separation of logical controls and secure storage locations provides defense-in-depth and protects against the loss of all keys, and your data, from a single attack or point of failure.
- The availability key provides a high-availability capability if Microsoft 365 services are unable to reach keys hosted in Azure Key Vault due to transient errors. This rule only applies to Exchange Online and Skype for Business service encryption. SharePoint Online, OneDrive for Business, and Teams files never use the availability key unless you explicitly instruct Microsoft to initiate the recovery process.

Sharing the responsibility to protect your data, using a variety of protections and processes for key management, ultimately reduces the risk that all keys (and therefore your data) will be permanently lost or destroyed. Microsoft provides you with sole authority over the disablement or destruction of the availability key when you leave the service. By design, no one at Microsoft has access to the availability key: it is only accessible by Microsoft 365 service code.

See the Microsoft Trust Center for more information about how we secure keys.

Availability key uses

The availability key provides recovery capability for scenarios in which an external malefactor or malicious insider steals control of your key vault, or when inadvertent mismanagement results in loss of root keys. This recovery capability applies to all Microsoft 365 services compatible with Customer Key. Individual services use the availability key differently. Microsoft 365 only uses the availability key in the ways described below.

Exchange Online and Skype for Business uses

In addition to the recovery capability, Exchange Online and Skype for Business use the availability key to ensure data availability during transient, or intermittent operational issues, related to the service accessing root keys. When the service cannot reach either of your Customer Keys in Azure Key Vault due to transient errors, the service automatically uses the availability key. The service NEVER goes directly to the availability key.

Automated systems in Exchange Online and Skype for Business may use the availability key during transient errors to support automated back-end services such as anti-virus, e-discovery, data loss prevention, mailbox moves, and data indexing.

SharePoint Online, OneDrive for Business, and Teams files uses

For SharePoint Online, OneDrive for Business, and Teams files, the availability key is NEVER used outside of the recovery capability and customers must explicitly instruct Microsoft to initiate use of the availability key during a recovery scenario. Automated service operations solely rely on your Customer Keys in Azure Key vault. For in-depth information about how the key hierarchy works for these services, see How SharePoint Online, OneDrive for Business, and Teams files use the availability key.

Availability key security

Microsoft shares the responsibility of data protection with you by instantiating the availability key and taking extensive measures to protect it. Microsoft does not expose direct control of the availability key to customers. For example, you can only roll (rotate) the keys that you own in Azure Key Vault. For more information, see Roll or rotate a customer key or an availability key.

Availability key secret stores

Microsoft protects availability keys in access-controlled, internal secret stores like the customer-facing Azure Key Vault. We implement access controls to prevent Microsoft administrators from directly accessing the secrets contained within. Secret Store operations, including key rotation and deletion, occur through automated commands that never involve direct access to the availability key. Secret store management operations are limited to specific engineers and require privilege escalation through an internal tool, Lockbox. Privilege escalation requires manager approval and justification prior to being granted. Lockbox ensures access is time bound with automatic access revocation upon time expiration or engineer log out.

Exchange Online and Skype for Business availability keys are stored in an Exchange Online Active Directory secret store. Availability keys are securely stored inside tenant specific containers within the Active Directory Domain Controller. This secure storage location is separate and isolated from the SharePoint Online, OneDrive for Business, and Teams files secret store.

SharePoint Online, OneDrive for Business, and Teams files availability keys are stored in an internal secret store managed by the service team. This secured, secrets storage service has front-end servers with application endpoints and a SQL Database as the back end. Availability keys are stored in the SQL Database and are wrapped (encrypted) by secret store encryption keys that use a combination of AES-256 and HMAC to encrypt the availability key at rest. The secret store encryption keys are stored in a logically isolated component of the same SQL Database and are further encrypted with RSA-2048 keys contained in certificates managed by the Microsoft certificate authority (CA). These certificates are stored in the secret store front-end servers that perform operations against the database.

Defense-in-depth

Microsoft employs a defense-in-depth strategy to prevent malicious actors from impacting the confidentiality, integrity, or availability of customer data stored in the Microsoft Cloud. Specific preventive and detective controls are implemented to protect the secret store and the availability key as part of the overarching security strategy.

Microsoft 365 is built to prevent misuse of the availability key. The application layer is the only method through which keys, including the availability key, can be used to encrypt and decrypt data. Only Microsoft 365 service code has the ability to interpret and traverse the key hierarchy for encryption and decryption activities. Logical isolation exists between the storage locations of Customer Keys, availability keys, other hierarchical keys, and customer data. This isolation mitigates the risk of data exposure in the event one or more locations are compromised. Each layer in the hierarchy has built in 24x7 intrusion detection capabilities to protect data and secrets stored.

Access controls are implemented to prevent unauthorized access to internal systems, including availability key secret stores. Microsoft engineers don't have direct access to the availability key secret stores. For additional detail on access controls, review Administrative Access Controls in Microsoft 365.

Technical controls prevent Microsoft personnel from logging into highly-privileged service accounts, which might otherwise be used by attackers to impersonate Microsoft services. For example, these controls prevent interactive logon.

Security logging and monitoring controls are another defense-in-depth safeguard implemented that mitigate risk to Microsoft services and your data. Microsoft service teams have deployed active monitoring solutions that generate alerts and audit logs. All service teams upload their logs to a central repository where the logs are aggregated and processed. Internal tools automatically examine records to confirm that services are functioning in an optimal, resilient, and secure state. Unusual activity is flagged for further review.

Any log event that indicates a potential violation of the Microsoft Security Policy is immediately brought to the attention of Microsoft security teams. Microsoft 365 security has configured alerts to detect attempted access to availability key secret stores. Alerts are also generated if Microsoft personnel attempt interactive logon to service accounts, which is prohibited and protected by access controls. Microsoft 365 security also detects and alerts upon deviations of the Microsoft 365 service from normal baseline operations. Malefactors attempting to misuse Microsoft 365 services would trigger alerts resulting in the offender's eviction from the Microsoft cloud environment.

Use the availability key to recover from key loss

If you lose control of your Customer Keys, the availability key provides you the ability to recover and re-encrypt your data.

Recovery procedure for Exchange Online and Skype for Business

If you lose control of your Customer Keys, the availability key gives you the capability to recover your data and bring your impacted Microsoft 365 resources back online. The availability key continues to protect your data while you recover.At a high level, to fully recover from key loss, you'll need to create a new DEP and move impacted resources to the new policy.

To encrypt your data with new Customer Keys, create new keys in Azure Key Vault, create a new DEP using the new Customer Keys, then assign the new DEP to the mailboxes currently encrypted with the previous DEP for which the keys were lost or compromised.

This re-encryption process can take up to 72 hours. This is the standard duration when you change a DEP.

Recovery procedure for SharePoint Online, OneDrive for Business, and Teams files

For SharePoint Online, OneDrive for Business, and Teams files, the availability key is NEVER used outside of the recovery capability. You must explicitly instruct Microsoft to initiate use of the availability key during a recovery scenario. To initiate the recovery process, contact Microsoft to activate the availability key. Once activated, the availability key is automatically used to decrypt your data allowing you to encrypt the data with a newly-created DEP associated to new Customer Keys.

This operation is proportional to the number of sites in your organization. Once you call Microsoft to use the availability key, you should be fully online within about four hours.

How Exchange Online and Skype for Business use the availability key

When you create a DEP with Customer Key, Microsoft 365 generates a Data Encryption Policy Key (DEP Key) associated with that DEP. The service encrypts the DEP Key three times: once with each of the customer keys and once with the availability key. Only the encrypted versions of the DEP Key are stored, and a DEP Key can only be decrypted with the customer keys or the availability key. The DEP Key is then used to encrypt Mailbox Keys, which encrypt individual mailboxes.

Microsoft 365 follows this process to decrypt and provide data when customers are using the service:

1. Decrypt the DEP Key using the Customer Key.

2. Use the decrypted DEP Key to decrypt a Mailbox Key.
3. Use the decrypted Mailbox Key to decrypt the mailbox itself, allowing you to access the data within the mailbox.

How SharePoint Online, OneDrive for Business, and Teams files use the availability key

The SharePoint Online and OneDrive for Business architecture and implementation for Customer Key and availability key are different from Exchange Online and Skype for Business.

When an organization moves to customer-managed keys, Microsoft 365 creates an organization-specific intermediate key (TIK). Microsoft 365 encrypts the TIK twice, once with each of the customer keys, and stores the two encrypted versions of the TIK. Only the encrypted versions of the TIK are stored, and a TIK can only be decrypted with the customer keys. The TIK is then used to encrypt site keys, which are then used to encrypt blob keys (also called file chunk keys). Depending on file size, the service may split a file into multiple file chunks each with a unique key. The blobs (file chunks) themselves are encrypted with the blob keys and stored in the Microsoft Azure Blob storage service.

Microsoft 365 follows this process to decrypt and provide customer files when customers are using the service:

1. Decrypt the TIK using the Customer Key.
2. Use the decrypted TIK to decrypt a site key.
3. Use the decrypted site key to decrypt a blob key.
4. Use the decrypted blob key to decrypt the blob.

Microsoft 365 decrypts a TIK by issuing two decryption requests to Azure Key Vault with a slight offset. The first one to finish furnishes the result, canceling the other request.

In case you lose access to your customer keys, Microsoft 365 also encrypts the TIK with an availability key and stores this along with the TIKs encrypted with each customer key. The TIK encrypted with the availability key is used only when the customer calls Microsoft to enlist the recovery path when they have lost access to their keys, maliciously or accidentally.

For availability and scale reasons, decrypted TIKs are cached in a time-limited memory cache. Two hours before a TIK cache is set to expire, Microsoft 365 attempts to decrypt each TIK. Decrypting the TIKs extends the lifetime of the cache. If TIK decryption fails for a significant amount of time, Microsoft 365 generates an alert to notify engineering prior to the cache expiration. Only if the customer calls Microsoft will Microsoft 365 initiate the recovery operation, which involves decrypting the TIK with the availability key stored in Microsoft's secret store and onboarding the tenant again using the decrypted TIK and a new set of customer-supplied Azure Key Vault keys.

As of today, Customer Key is involved in the encryption and decryption chain of SharePoint Online file data stored in the Azure blob store, but not SharePoint Online list items or metadata stored in the SQL Database. Microsoft 365 does not use the availability key for Exchange Online, Skype for Business, SharePoint Online, OneDrive for Business, and Teams files other than the case described above, which is customer-initiated. Human access to customer data is protected by Customer Lockbox.

Availability key triggers

Microsoft 365 triggers the availability key only in specific circumstances. These circumstances differ by service.

Triggers for Exchange Online and Skype for Business

1. Microsoft 365 reads the DEP to which the mailbox is assigned in order to determine the location of the

two Customer Keys in Azure Key Vault.

2. Microsoft 365 randomly chooses one of the two Customer Keys from the DEP and sends a request to Azure Key Vault to unwrap the DEP key using the Customer Key.
3. If the request to unwrap the DEP key using the Customer Key fails, Microsoft 365 sends a second request to Azure Key Vault, this time instructing it to use the alternate (second) Customer Key.
4. If the second request to unwrap the DEP key using the Customer Key fails, Microsoft 365 examines the results of both requests.
    - If the examination determines that the requests failed returning a system ERROR:
        - Microsoft 365 triggers the availability key to decrypt the DEP key.
        - Microsoft 365 then uses the DEP key to decrypt the mailbox key and complete the user request.
        - In this case, Azure Key Vault is either unable to respond or unreachable due to a transient ERROR.
    - If the examination determines that the requests failed returning ACCESS DENIED:
        - This means deliberate, inadvertent, or malicious action has been taken to render the customer keys unavailable (for example, during the data purge process as part of leaving the service).
        - In this case, the availability key will be used only for system actions and not for user actions, the user request fails, and the user receives an error message.

> **IMPORTANT**
> Microsoft 365 service code always has a valid login token for reasoning over customer data to provide value-adding cloud services. Therefore, until the availability key has been deleted, it can be used as a fallback for actions initiated by, or internal to, Exchange Online and Skype for Business such as search index creation or moving mailboxes. This applies to both transient ERRORS and ACCESS DENIED requests to Azure Key Vault.

Triggers for SharePoint Online, OneDrive for Business, and Teams files

For SharePoint Online, OneDrive for Business, and Teams files, the availability key is NEVER used outside of the recovery capability and customers must explicitly instruct Microsoft to initiate use of the availability key during a recovery scenario.

Audit logs and the availability key

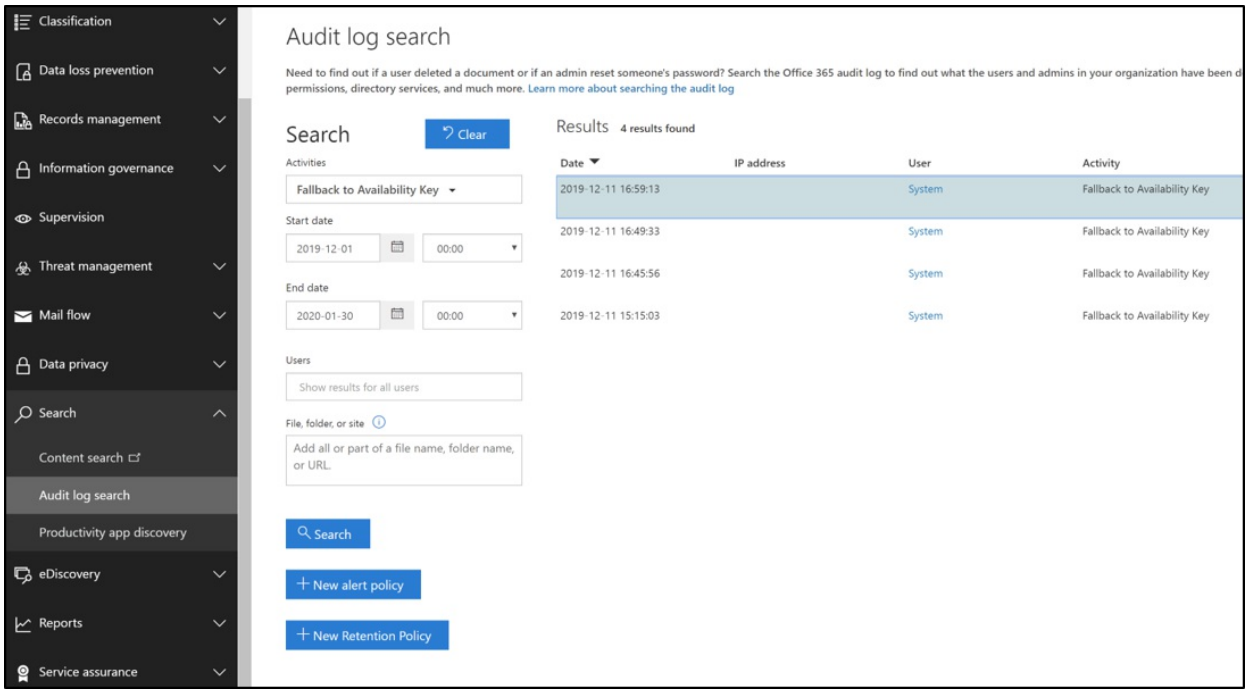
Automated systems in Microsoft 365 process all data as it flows through the system to provide cloud services, for example, anti-virus, e-discovery, data loss prevention, and data indexing. Microsoft 365 does not generate customer-visible logs for this activity. In addition, Microsoft personnel do not access your data as part of these normal system operations.

Exchange Online and Skype for Business availability key logging

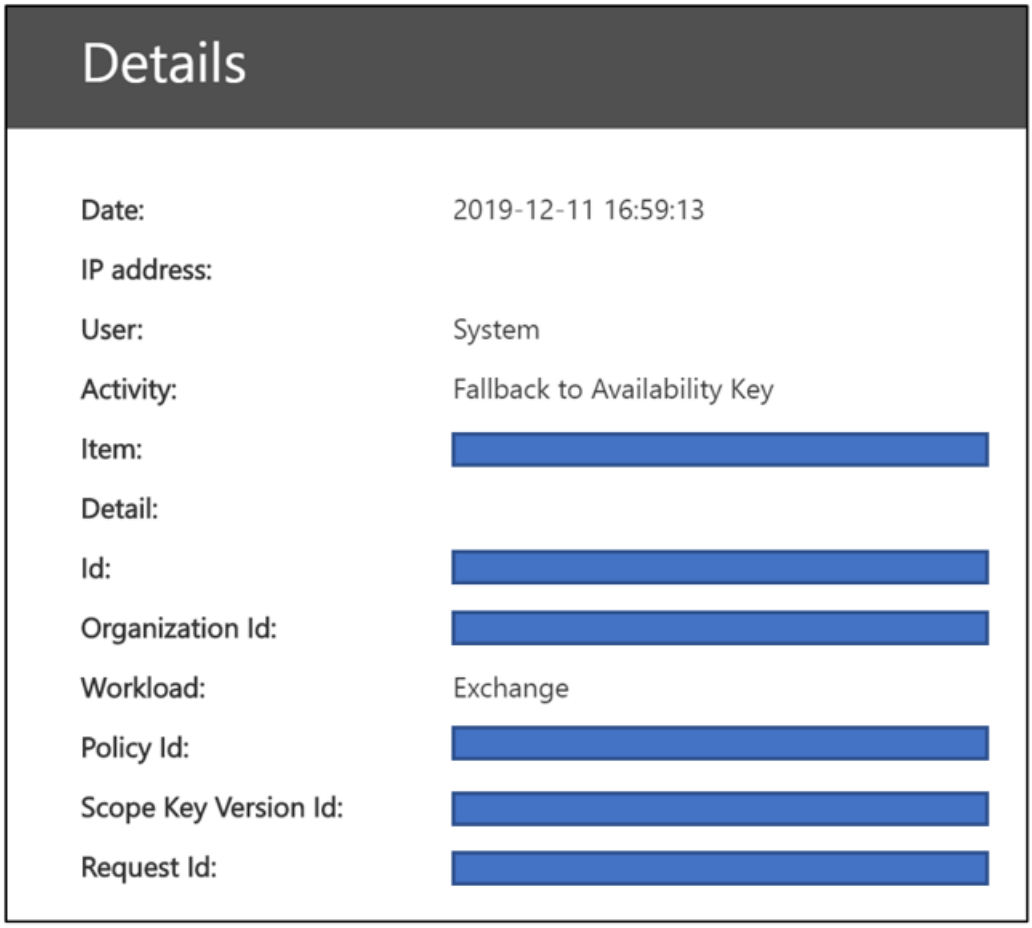
When Exchange Online and Skype for Business accesses availability key to provide service, Microsoft 365 publishes customer-visible logs accessible from the Security and Compliance Center. An audit log record for the availability key operation is generated each time the service uses the availability key. A new record type called "Customer Key Service Encryption" with activity type "Fallback to Availability Key" allows admins to filter Unified Audit Log search results to view availability key records.

Log records include attributes such as date, time, activity, organization ID, and data encryption policy ID. The

record is available as part of Unified Audit Logs and is accessible from the Security & Compliance Center Audit Log Search tab.



Exchange Online and Skype for Business availability key records use the Office 365 Management Activity common schema with added custom parameters: Policy Id, Scope Key Version Id, and Request Id.



SharePoint Online, OneDrive for Business, and Teams files availability key logging

Availability key logging isn't available yet for these services. For SharePoint Online, OneDrive for Business, and Teams files, the availability key is only activated by Microsoft, when instructed by you, for recovery purposes. As a result, you already know every event in which the availability key is used for these services.

Availability key in the Customer Key hierarchy

Microsoft 365 uses the availability key to wrap the tier of keys lower in the key hierarchy established for Customer Key service encryption. Different key hierarchies exist between services. Key algorithms also differ between availability keys and other keys in the hierarchy of each applicable service. The availability key algorithms used by the different services are as follows:

- The Exchange Online and Skype for Business availability keys use AES-256.
- The SharePoint Online, OneDrive for Business, and Teams files availability keys use RSA-2048.

Email encryption

2/18/2021 • 6 minutes to read • Edit Online

This article compares encryption options in Microsoft 365 including Office 365 Message Encryption (OME), S/MIME, Information Rights Management (IRM), and introduces Transport Layer Security (TLS).

Microsoft 365 delivers multiple encryption options to help you meet your business needs for email security. This article presents three ways to encrypt email in Office 365. If you want to learn more about all security features in Office 365, visit the Office 365 Trust Center. This article introduces the three types of encryption available for Microsoft 365 administrators to help secure email in Office 365:

- Office Message Encryption (OME).
- Secure/Multipurpose Internet Mail Extensions (S/MIME).
- Information Rights Management (IRM).

How Microsoft 365 uses email encryption

Encryption is the process by which information is encoded so that only an authorized recipient can decode and consume the information. Microsoft 365 uses encryption in two ways: in the service, and as a customer control. In the service, encryption is used in Microsoft 365 by default; you don't have to configure anything. For example, Microsoft 365 uses Transport Layer Security (TLS) to encrypt the connection, or session, between two servers.

Here's how email encryption typically works:

- A message is encrypted, or transformed from plain text into unreadable ciphertext, either on the sender's machine, or by a central server while the message is in transit.
- The message remains in ciphertext while it's in transit in order to protect it from being read in case the message is intercepted.
- Once the message is received by the recipient, the message is transformed back into readable plain text in one of two ways:
    - The recipient's machine uses a key to decrypt the message, or
    - A central server decrypts the message on behalf of the recipient, after validating the recipient's identity.

For more information on how Microsoft 365 secures communication between servers, such as between organizations within Microsoft 365 or between Microsoft 365 and a trusted business partner outside of Microsoft 365, see How Exchange Online uses TLS to secure email connections in Office 365.

Watch this video for an introduction to Encryption in Office 365.

Comparing email encryption options available in Office 365

EMAIL ENCRYPTION TECHNOLOGY	OME 	IRM 	S/MIME 
What is it?	Office 365 Message Encryption (OME) is a service built on Azure Rights Management (Azure RMS) that lets you send encrypted email to people inside or outside your organization, regardless of the destination email address (Gmail, Yahoo! Mail, Outlook.com, etc.). As an admin, you can set up transport rules that define the conditions for encryption. When a user sends a message that matches a rule, encryption is applied automatically. To view encrypted messages, recipients can either get a one-time passcode, sign in with a Microsoft account, or sign in with a work or school account associated with Office 365. Recipients can also send encrypted replies. They don't need a Microsoft 365 subscription to view encrypted messages or send encrypted replies.	IRM is an encryption solution that also applies usage restrictions to email messages. It helps prevent sensitive information from being printed, forwarded, or copied by unauthorized people. IRM capabilities in Microsoft 365 use Azure Rights Management (Azure RMS).	S/MIME is a certificate-based encryption solution that allows you to both encrypt and digitally sign a message. The message encryption helps ensure that only the intended recipient can open and read the message. A digital signature helps the recipient validate the identity of the sender. Both digital signatures and message encryption are made possible through the use of unique digital certificates that contain the keys for verifying digital signatures and encrypting or decrypting messages. To use S/MIME, you must have public keys on file for each recipient. Recipients have to maintain their own private keys, which must remain secure. If a recipient's private keys are compromised, the recipient needs to get a new private key and redistribute public keys to all potential senders.
What does it do?	OME: Encrypts messages sent to internal or external recipients. Allows users to send encrypted messages to any email address, including Outlook.com, Yahoo! Mail, and Gmail. Allows you, as an admin, to customize the email viewing portal to reflect your organization's brand. Microsoft securely manages and stores the keys, so you don't have to. No special client side software is needed as long as the encrypted message (sent as an HTML attachment) can be opened in a browser.	IRM: Uses encryption and usage restrictions to provide online and offline protection for email messages and attachments. Gives you, as an admin, the ability to set up transport rules or Outlook protection rules to automatically apply IRM to select messages. Lets users manually apply templates in Outlook or Outlook on the web (formerly known as Outlook Web App).	S/MIME addresses sender authentication with digital signatures, and message confidentiality with encryption.

EMAIL ENCRYPTION TECHNOLOGY	OME 	IRM 	S/MIME 
What does it not do?	OME doesn't let you apply usage restrictions to messages. For example, you can't use it to stop a recipient from forwarding or printing an encrypted message.	Some applications may not support IRM emails on all devices. For more information about these and other products that support IRM email, see Client device capabilities.	S/MIME doesn't allow encrypted messages to be scanned for malware, spam, or policies.
Recommendations and example scenarios	We recommend using OME when you want to send sensitive business information to people outside your organization, whether they're consumers or other businesses. For example: A bank employee sending credit card statements to customers A doctor's office sending medical records to a patient An attorney sending confidential legal information to another attorney	We recommend using IRM when you want to apply usage restrictions as well as encryption. For example: A manager sending confidential details to her team about a new product applies the "Do Not Forward" option. An executive needs to share a bid proposal with another company, which includes an attachment from a partner who is using Office 365, and require both the email and the attachment to be protected.	We recommend using S/MIME when either your organization or the recipient's organization requires true peer-to-peer encryption. S/MIME is most commonly used in the following scenarios: Government agencies communicating with other government agencies A business communicating with a government agency

What encryption options are available for my Microsoft 365 subscription?

For information about email encryption options for your Microsoft 365 subscription see the Exchange Online service description. Here, you can find information about the following encryption features:

- Azure RMS, including both IRM capabilities and OME
- S/MIME
- TLS
- Encryption of data at rest (through BitLocker)

You can also use third-party encryption tools with Microsoft 365, for example, PGP (Pretty Good Privacy). Microsoft 365 does not support PGP/MIME and you can only use PGP/Inline to send and receive PGP-encrypted emails.

What about encryption for data at rest?

"Data at rest" refers to data that isn't actively in transit. In Microsoft 365, email data at rest is encrypted using BitLocker Drive Encryption. BitLocker encrypts the hard drives in Microsoft datacenters to provide enhanced protection against unauthorized access. To learn more, see BitLocker Overview.

Message Encryption

2/18/2021 • 7 minutes to read • Edit Online

People often use email to exchange sensitive information, such as financial data, legal contracts, confidential product information, sales reports and projections, patient health information, or customer and employee information. As a result, mailboxes can become repositories for large amounts of potentially sensitive information and information leakage can become a serious threat to your organization.

With Office 365 Message Encryption, your organization can send and receive encrypted email messages between people inside and outside your organization. Office 365 Message Encryption works with Outlook.com, Yahoo!, Gmail, and other email services. Email message encryption helps ensure that only intended recipients can view message content.

How Office 365 Message Encryption works

The rest of this article applies to the new OME capabilities.

Office 365 Message Encryption is an online service that's built on Microsoft Azure Rights Management (Azure RMS) which is part of Azure Information Protection. This includes encryption, identity, and authorization policies to help secure your email. You can encrypt messages by using rights management templates, the Do Not Forward option, and the encrypt-only option.

Users can then encrypt email messages and a variety of attachments by using these options. For a full list of supported attachment types, see "File types covered by IRM policies when they are attached to messages" in Introduction to IRM for email messages.

As an administrator, you can also define mail flow rules to apply this protection. For example, you can create a rule that requires the encryption of all messages addressed to a specific recipient, or that contains specific words in the subject line, and also specify that recipients can't copy or print the contents of the message.

Unlike the previous version of OME, the new capabilities provide a unified sender experience whether you're sending mail inside your organization or to recipients outside of Microsoft 365. In addition, recipients who receive a protected email message sent to a Microsoft 365 account in Outlook 2016 or Outlook on the web, don't have to take any additional action to view the message. It works seamlessly. Recipients using other email clients and email service providers also have an improved experience. For information, see Learn about protected messages in Office 365 and How do I open a protected message.

For a detailed list of the differences between the previous version of OME and the new OME capabilities, see Compare versions of OME.

When someone sends an email message that matches an encryption mail flow rule, the message is encrypted before it's sent. All Microsoft 365 end users that use Outlook clients to read mail receive native, first-class reading experiences for encrypted and rights-protected mail even if they're not in the same organization as the sender. Supported Outlook clients include Outlook desktop, Outlook Mac, Outlook mobile on iOS and Android, and Outlook on the web (formerly known as Outlook Web App).

Recipients of encrypted messages who receive encrypted or rights-protected mail sent to their Outlook.com, Gmail, and Yahoo accounts receive a wrapper mail that directs them to the OME Portal where they can easily authenticate using a Microsoft account, Gmail, or Yahoo credentials.

End users that read encrypted or rights-protected mail on clients other than Outlook also use the OME portal to view encrypted and rights-protected messages that they receive.

If the sender of the protected mail is in GCC High and the recipient is outside of GCC High, including commercial users, Outlook.com users, and users of other email providers such as Gmail, the recipient receives a wrapper mail. The wrapper mail directs the recipient to the OME Portal where the recipient is able to read and reply to the message. Otherwise, if the sender and recipient are both in the GCC High environment, even if they're not in the same organization, then recipients that use Outlook clients to read mail receive native, first-class reading experiences for encrypted and rights-protected mail. For more information about the different experience in GCC High, see Compare versions of OME.

For more information about size limits for messages and attachments that you can encrypt using OME, see Exchange Online Limits.

How Office 365 Advanced Message Encryption works on top of OME

Office 365 Advanced Message Encryption lets you create multiple branding templates so you can fine-tune control over recipient mail and create custom branding experiences to support a diverse organizational structure.

Advanced Message Encryption in Microsoft 365 helps you meet compliance obligations that require more flexible control over external recipient's access to encrypted emails. With Advanced Message Encryption in Office 365, as an administrator, you can control sensitive emails shared outside the organization with automatic policies that detect sensitive information types (for example, PII, Financial or Health IDs) or keywords to enhance protection by expiring access through a secure web portal to encrypted emails. As an admin you can further control encrypted emails accessed through a Microsoft 365 web portal by revoking access to an email anytime.

Message revocation and expiration only work for emails that your users send to recipients outside your organization. In addition, the recipients must access the email through the web portal. To ensure the recipient uses the portal to receive email, you set up a custom branding template that applies the wrapper. Then, you apply the branding template in a mail flow rule. For more information about Advanced Message Encryption, see Office 365 Advanced Message Encryption.

Defining rules for Office 365 Message Encryption

One way to enable the new capabilities for Office 365 Message Encryption is for Exchange Online and Exchange Online Protection administrators to define mail flow rules. These rules determine under what conditions email messages should be encrypted. When an encryption action is set for a rule, any messages that match the rule conditions are encrypted before they're sent.

Mail flow rules are flexible, letting you combine conditions so you can meet specific security requirements in a single rule. For example, you can create a rule to encrypt all messages that contain specified keywords and are addressed to external recipients. The new capabilities for Office 365 Message Encryption also encrypt replies from recipients of encrypted email.

For more information about how to create mail flow rules to take advantage of the new OME capabilities, see Define Rules for Office 365 Message Encryption.

Get started with the new OME capabilities

If you're ready to get started using the new OME capabilities within your organization, see Set up new Office 365 Message Encryption capabilities.

Sending, viewing, and replying to encrypted email messages

With Office 365 Message Encryption, users can send encrypted email from Outlook and Outlook on the web. Additionally, admins can set up mail flow rules in Microsoft 365 to automatically encrypt emails based on keyword matching or other conditions.

Recipients of encrypted messages who are in organizations will be able to read those messages seamlessly in any version Outlook, including Outlook for PC, Outlook for Mac, Outlook on the web, Outlook for iOS, and Outlook for Android. Users that receive encrypted messages on other email clients can view the messages in the OME portal.

For detailed guidance about how to send and view encrypted messages, take a look at these articles.

View encrypted messages on your Android device	An end user who has received a message encrypted with Office 365 Message Encryption on your Android device, you can use the free OME Viewer app to view the message and send an encrypted reply. This article explains how.
View encrypted messages on your iPhone or iPad	An end user who has received a message encrypted with Office 365 Message Encryption on your iPhone or iPad, you can use the free OME Viewer app to view the message and send an encrypted reply. This article explains how.

Set up new Message Encryption capabilities

11/2/2020 • 4 minutes to read • Edit Online

The new Office 365 Message Encryption (OME) capabilities allow organizations to share protected email with anyone on any device. Users can exchange protected messages with other Microsoft 365 organizations, as well as non-customers using Outlook.com, Gmail, and other email services.

Follow the steps below to ensure that the new OME capabilities are available in your organization.

Verify that Azure Rights Management is active

The new OME capabilities leverage the protection features in Azure Rights Management Services (Azure RMS), the technology used by Azure Information Protection to protect emails and documents via encryption and access controls.

The only prerequisite for using the new OME capabilities is that Azure Rights Management must be activated in your organization's tenant. If it is, Microsoft 365 activates the new OME capabilities automatically and you don't need to do anything.

Azure RMS is also activated automatically for most eligible plans, so you probably don't have to do anything in this regard either. See Activating Azure Rights Management for more information.

> **IMPORTANT**
>
> If you use Active Directory Rights Management service (AD RMS) with Exchange Online, you need to migrate to Azure Information Protection before you can use the new OME capabilities. OME is not compatible with AD RMS.

For more information, see:

- What subscriptions do I need to use the new OME capabilities? to check whether your subscription plan includes Azure Information Protection (which includes Azure RMS functionality).
- Azure Information Protection for information about purchasing an eligible subscription.

Manually activating Azure Rights Management

If you disabled Azure RMS, or if it was not automatically activated for any reason, you can activate it manually in the:

- **Microsoft 365 admin center**: See How to activate Azure Rights Management from the admin center for instructions.
- **Azure portal**: See How to activate Azure Rights Management from the Azure portal for instructions.

Configure management of your Azure Information Protection tenant key

This is an optional step. Allowing Microsoft to manage the root key for Azure Information Protection is the default setting and recommended best practice for most organizations. If this is the case, you don't need to do anything.

There are many reasons, for example compliance requirements, that may necessitate you generating and managing your own root key (also known as bring your own key (BYOK)). If this is the case, we recommend that you complete the required steps before setting up the new OME capabilities. See Planning and implementing

your Azure Information Protection tenant key for more.

Verify new OME configuration in Exchange Online PowerShell

You can verify that your Microsoft 365 tenant is properly configured to use the new OME capabilities in Exchange Online PowerShell.

1. Connect to Exchange Online PowerShell using an account with global administrator permissions in your Microsoft 365 tenant.
2. Run the Get-IRMConfiguration cmdlet.

   You should see a value of $True for the AzureRMSLicensingEnabled parameter, which indicates that OME is configured in your tenant. If it is not, use Set-IRMConfiguration to set the value of AzureRMSLicensingEnabled to $True to enable OME.
3. Run the Test-IRMConfiguration cmdlet using the following syntax:

   ```
   Test-IRMConfiguration [-Sender <email address >]
   ```

   Example:

   ```
   Test-IRMConfiguration -Sender securityadmin@contoso.com
   ```

   - Providing a sender email is optional, but forces the system to perform additional checks. Use the email address of any user in your Microsoft 365 tenant.

   Your results should be similar to:

   ```
   Results : Acquiring RMS Templates ...
             - PASS: RMS Templates acquired.  Templates available: Contoso  - Confidential View Only,
   Contoso  - Confidential, Do Not
          Forward.
          Verifying encryption ...
              - PASS: Encryption verified successfully.
          Verifying decryption ...
              - PASS: Decryption verified successfully.
          Verifying IRM is enabled ...
              - PASS: IRM verified successfully.

          OVERALL RESULT: PASS
   ```

   - Your organization name will replace *Contoso*.
   - The default template names may be different from those displayed above. See Configuring and managing templates for Azure Information Protection for more.
4. Run the Remove-PSSession cmdlet to disconnect from the Rights Management service.

   ```
   Remove-PSSession $session
   ```

Next steps: Define mail flow rules to use new OME capabilities

If there are previously configured mail flow rules to encrypt email in your organization, you need to update the existing rules to use the new OME capabilities. For new deployments, you need to create new mail flow rules.

IMPORTANT

If you do not update existing mail flow rules, your users will continue to receive encrypted mail that uses the previous HTML attachment format, instead of the new seamless OME experience.

Mail flow rules determine under what conditions email messages should be encrypted, as well as conditions for removing that encryption. When you set an action for a rule, any messages that match the rule conditions are encrypted when they're sent.

For steps on creating mail flow rules for OME, see Define mail flow rules to encrypt email messages in Office 365.

To update existing rules to use the new OME capabilities:

1. In the Microsoft 365 admin center, go to **Admin centers > Exchange**.
2. In the Exchange admin center, go to **Mail flow > Rules**.
3. For each rule, in **Do the following**:
   - Select **Modify the message security**.
   - Select **Apply Office 365 Message Encryption and rights protection**.
   - Select an RMS template from the list.
   - Select **Save**.
   - Select **OK**.

Define mail flow rules to encrypt email messages

11/2/2020 • 6 minutes to read • Edit Online

As a global administrator, you can create mail flow rules (also known as transport rules) to help protect email messages you send and receive. You can set up rules to encrypt any outgoing email messages and remove encryption from encrypted messages coming from inside your organization or from replies to encrypted messages sent from your organization. You can use the Exchange admin center (EAC) or Exchange Online PowerShell to create these rules. In addition to overall encryption rules, you can also choose to enable or disable individual message encryption options for end users.

You can't encrypt inbound mail from senders outside of your organization.

If you recently migrated from Active Directory RMS to Azure Information Protection, you'll need to review your existing mail flow rules to ensure that they continue to work in your new environment. Also, if you want to take advantage of the new Office 365 Message Encryption (OME) capabilities available to you through Azure Information Protection, you need to update your existing mail flow rules. Otherwise, your users will continue to receive encrypted mail that uses the previous HTML attachment format instead of the new, seamless OME experience. If you haven't set up OME yet, see Set up new Office 365 Message Encryption capabilities for information.

For information about the components that make up mail flow rules and how mail flow rules work, see Mail flow rules (transport rules) in Exchange Online. For additional information about how mail flow rules work with Azure Information Protection, see Configuring Exchange Online mail flow rules for Azure Information Protection labels.

> **IMPORTANT**
>
> For hybrid Exchange environments, on-premises users can send and receive encrypted mail using OME only if email is routed through Exchange Online. To configure OME in a hybrid Exchange environment, you need to first configure hybrid using the Hybrid Configuration wizard and then configure mail to flow from Office 365 to your email server and configure mail to flow from your email server to Office 365. Once you've configured mail to flow through Office 365, then you can configure mail flow rules for OME by using this guidance.

Create mail flow rules to encrypt email messages with the new OME capabilities

You can define mail flow rules for triggering message encryption with the new OME capabilities by using the EAC.

Use the EAC to create a rule for encrypting email messages with the new OME capabilities

1. In a web browser, using a work or school account that has been granted global administrator permissions, sign in to Office 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Encrypt mail for DrToniRamos@hotmail.com.

6. In **Apply this rule if**, select a condition, and enter a value if necessary. For example, to encrypt messages going to DrToniRamos@hotmail.com:

   a. In **Apply this rule if**, select **the recipient is**.

   b. Select an existing name from the contact list or type a new email address in the **check names** box.

      - To select an existing name, select it from the list and then click **OK**.
      - To enter a new name, type an email address in the **check names** box and then select **check names** > **OK**.

7. To add more conditions, choose **More options** and then choose **add condition** and select from the list.

   For example, to apply the rule only if the recipient is outside your organization, select **add condition** and then select **The recipient is external/internal** > **Outside the organization** > **OK**.

8. To enable encryption using the new OME capabilities, from **Do the following**, select **Modify the message security** and then choose **Apply Office 365 Message Encryption and rights protection**. Select an RMS template from the list, choose **Save**, and then choose **OK**.

The list of templates includes all default templates and options as well as any custom templates you've created for use by Office 365. If the list is empty, ensure that you have set up Office 365 Message Encryption with the new capabilities as described in Set up new Office 365 Message Encryption capabilities. For information about the default templates, see Configuring and managing templates for Azure Information Protection. For information about the **Do Not Forward** option, see Do Not Forward option for emails. For information about the **encrypt only** option, see Encrypt Only option for emails.

You can choose **add action** if you want to specify another action.

Use the EAC to update an existing mail flow rule to use the new OME capabilities

1. In a web browser, using a work or school account that has been granted global administrator permissions, sign in to Office 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules**.
5. In the list of mail flow rules, select the rule you want to modify to use the new OME capabilities and then choose **Edit** ✎.
6. To enable encryption using the new OME capabilities, from **Do the following**, choose **Modify the message security** and then choose **Apply Office 365 Message Encryption and rights protection**. Select an RMS template from the list, choose **Save** and then choose **OK**.

   The list of templates includes all default templates and options as well as any custom templates you've created for use by Office 365. If the list is empty, ensure that you have set up Office 365 Message Encryption with the new capabilities as described in Set up new Office 365 Message Encryption capabilities built on top of Azure Information Protection. For information about the default templates, see Configuring and managing templates for Azure Information Protection. For information about the **Do Not Forward** option, see Do Not Forward option for emails. For information about the **encrypt only** option, see Encrypt Only option for emails.

   You can choose **add action** if you want to specify another action.

7. From the **Do the following** list, remove any actions that are assigned to **Modify the message security** > **Apply the previous version of OME**.

8. Choose **Save**.

Create mail flow rules to remove encryption for outgoing email messages with the new OME capabilities

You can define mail flow rules for triggering remove message encryption with the new OME capabilities by using the EAC.

Use the EAC to create a rule to remove encryption from email messages with the new OME capabilities

1. In a web browser, using a work or school account that has been granted global administrator permissions, sign in to Office 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Remove encryption from outgoing mail.
6. In **Apply this rule if**, select the conditions where encryption should be removed from messages. Add **The sender is located** > **Inside the organization**. Now add additional conditions to target specific recipients, such as **The recipient is located** > **Outside the organization**.
7. In **Do the following**, select **Modify the message security** > **Remove Office 365 Message Encryption and rights protection**.
8. Select **Save**.

Create mail flow rules for Office 365 Message Encryption without the new capabilities

If you haven't yet moved your organization to the new OME capabilities, Microsoft recommends that you make a plan to move to the new OME capabilities as soon as it is reasonable for your organization. For instructions, see Set up new Office 365 Message Encryption capabilities built on top of Azure Information Protection. Otherwise, see Defining mail flow rules for Office 365 Message Encryption that don't use the new OME capabilities.

Add your organization's brand to your Microsoft 365 for business Message Encryption encrypted messages

2/18/2021 • 10 minutes to read • Edit Online

You can apply your company branding to customize the look of your organization's email messages and the encryption portal. You'll need to apply global administrator permissions to your work or school account before you can get started. Once you have these permissions, use the Get-OMEConfiguration and Set-OMEConfiguration Windows PowerShell cmdlets to customize these parts of encrypted email messages:

- Introductory text
- Disclaimer text
- URL for Your organization's privacy statement
- Text in the OME portal
- Logo that appears in the email message and OME portal, or whether to use a logo at all
- Background color in the email message and OME portal

You can also revert back to the default look and feel at any time.

If you'd like more control, use Office 365 Advanced Message Encryption to create multiple templates for encrypted emails originating from your organization. Use these templates to control parts of the end-user experience. For example, specify whether recipients can use Google, Yahoo, and Microsoft Accounts to sign in to the encryption portal. Use templates to fulfill several use cases, such as:

- Individual departments, such as Finance, Sales, and so on.
- Different products
- Different geographical regions or countries
- Whether you want to allow emails to be revoked
- Whether you want emails sent to external recipients to expire after a specified number of days.

Once you've created the templates, you can apply them to encrypted emails by using Exchange mail flow rules. If you have Office 365 Advanced Message Encryption, you can revoke any email that you've branded by using these templates.

Work with OME branding templates

You can modify several features within a branding template. You can modify, but not remove, the default template. If you have Advanced Message Encryption, you can also create, modify, and remove custom templates. Use Windows PowerShell to work with one branding template at a time.

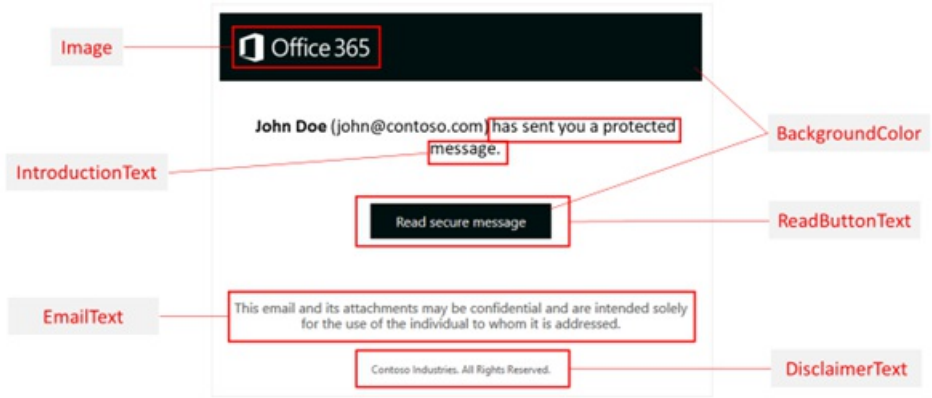
- Set-OMEConfiguration - Modify the default branding template or a custom branding template that you created.
- New-OMEConfiguration - Create a new branding template, Advanced Message Encryption only.
- Remove-OMEConfiguration - Remove a custom branding template, Advanced Message Encryption only. You

can't delete the default branding template.

Modify an OME branding template

Use Windows PowerShell to modify one branding template at a time. If you have Advanced Message Encryption, you can also create, modify, and remove custom templates.

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Use the Set-OMEConfiguration cmdlet as described in Set-OMEConfiguration or use the following graphic and table for guidance.



TO CUSTOMIZE THIS FEATURE OF THE ENCRYPTION EXPERIENCE	USE THESE COMMANDS

Background color	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -BackgroundColor "<#RRGGBB hexadecimal color code or name value>"`
	Example:
	`Set-OMEConfiguration -Identity "Branding Template 1" -BackgroundColor "#ffffff"`
	For more information about background colors, see the Background colors section later in this article.

Logo	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -Image <Byte[]>`
	Example:
	`Set-OMEConfiguration -Identity "Branding Template 1" -Image (Get-Content "C:\Temp\contosologo.png" -Encoding byte)`
	Supported file formats: .png, .jpg, .bmp, or .tiff
	Optimal size of logo file: less than 40 KB
	Optimal size of logo image: 170x70 pixels. If your image exceeds these dimensions, the service resizes your logo for display in the portal. The service doesn't modify the graphic file itself. For best results, use the optimal size.

Text next to the sender's name and email address	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -IntroductionText "<String up to 1024 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "Branding Template 1" -IntroductionText "has sent you a secure message."`

TO CUSTOMIZE THIS FEATURE OF THE ENCRYPTION EXPERIENCE	USE THESE COMMANDS

Text that appears on the "Read Message" button	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -ReadButtonText "<String up to 1024 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -ReadButtonText "Read Secure Message."`

Text that appears below the "Read Message" button	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -EmailText "<String up to 1024 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -EmailText "Encrypted message from ContosoPharma secure messaging system."`

URL for the Privacy Statement link	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -PrivacyStatementURL "<URL>"`
	Example:
	`Set-OMEConfiguration -Identity "Branding Template 1" -PrivacyStatementURL "https://contoso.com/privacystatement.html"`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -DisclaimerText "<Disclaimer statement. String of up to 1024 characters.>"`
	Example:
	`Set-OMEConfiguration -Identity "Branding Template 1" -DisclaimerText "This message is confidential for the use of the addressee only."`

Text that appears at the top of the encrypted mail viewing portal	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -PortalText "<Text for your portal. String of up to 128 characters.>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -PortalText "ContosoPharma secure email portal."`

To enable or disable authentication with a one-time pass code for this custom template	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -OTPEnabled <$true\|$false>`
	Examples:
	To enable one-time passcodes for this custom template
	`Set-OMEConfiguration -Identity "Branding Template 1" -OTPEnabled $true`
	To disable one-time passcodes for this custom template
	`Set-OMEConfiguration -Identity "Branding Template 1" -OTPEnabled $false`

To enable or disable authentication with Microsoft, Google, or Yahoo identities for this custom template	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -SocialIdSignIn <$true\|$false>`
	Examples:
	To enable social IDs for this custom template
	`Set-OMEConfiguration -Identity "Branding Template 1" -SocialIdSignIn $true`
	To disable social IDs for this custom template
	`Set-OMEConfiguration -Identity "Branding Template 1" -SocialIdSignIn $false`

Create an OME branding template (Advanced Message Encryption)

If you have Office 365 Advanced Message Encryption, you can create custom branding templates for your organization by using the New-OMEConfiguration cmdlet. Once you've created the template, you modify the template by using the Set-OMEConfiguration cmdlet as described in Modify an OME branding template. You can create multiple templates.

To create a new custom branding template:

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Use the New-OMEConfiguration cmdlet to create a new template.

   ```
   New-OMEConfiguration -Identity "<OMEConfigurationName>"
   ```

   For example,

   ```
   New-OMEConfiguration -Identity "Custom branding template"
   ```

Return the default branding template to its original values

To remove all modifications from the default template, including brand customizations, and so on, complete these steps:

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Use the **Set-OMEConfiguration** cmdlet as described in Set-OMEConfiguration. To remove your organization's branded customizations from the DisclaimerText, EmailText, and PortalText values, set the value to an empty string, `""`. For all image values, such as Logo, set the value to `"$null"`.

   The following table describes the encryption customization option defaults.

USE THESE COMMANDS	

Default text that comes with encrypted email messages The default text appears above the instructions for viewing encrypted messages	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -EmailText "<empty string>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -EmailText ""`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" DisclaimerText "<empty string>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -DisclaimerText ""`

Text that appears at the top of the encrypted mail viewing portal	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -PortalText "<empty string>"`
	Example reverting back to default:
	`Set-OMEConfiguration -Identity "OME Configuration" -PortalText ""`

USE THESE COMMANDS	

Logo	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -Image <"$null">`
	Example reverting back to default:
	`Set-OMEConfiguration -Identity "OME configuration" -Image $null`

Background color	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -BackgroundColor "$null">`
	Example reverting back to default:
	`Set-OMEConfiguration -Identity "OME configuration" -BackgroundColor $null`

Remove a custom branding template (Advanced Message Encryption)

You can only remove or delete branding templates that you've made. You can't remove the default branding template.

To remove a custom branding template:

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Use the **Remove-OMEConfiguration** cmdlet as follows:

   ```
   Remove-OMEConfiguration -Identity ""<OMEConfigurationName>"
   ```

   For example,

   ```
   Remove-OMEConfiguration -Identity "Branding template 1"
   ```

   For more information, see Remove-OMEConfiguration.

Create an Exchange mail flow rule that applies your custom branding to encrypted emails

After you've either modified the default template or created new branding templates, you can create Exchange mail flow rules to apply your custom branding based on certain conditions. Such a rule will apply custom branding in the following scenarios:

- If the email was manually encrypted by the end user using Outlook or Outlook on the web, formerly Outlook Web App
- If the email was automatically encrypted by an Exchange mail flow rule or Data Loss Prevention policy

For information on how to create an Exchange mail flow rule that applies encryption, see Define mail flow rules to encrypt email messages in Office 365.

1. In a web browser, using a work or school account that has been granted global administrator permissions, sign in to Office 365.
2. Choose the **Admin** tile.

3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Branding for sales department.
6. In **Apply this rule if**, select the condition **The sender is located inside the organization** and other conditions you want from the list of available conditions. For example, you might want to apply a particular branding template to:
   - All encrypted emails sent from members of the finance department
   - Encrypted emails sent with a certain keyword such as "External" or "Partner"
   - Encrypted emails sent to a particular domain
7. From **Do the following**, select **Modify the message security** > **Apply custom branding to OME messages**. Next, from the drop-down, select a branding template.
8. (Optional) You can configure the mail flow rule to apply encryption and custom branding. From **Do the following**, select **Modify the message security**, and then choose **Apply Office 365 Message Encryption and rights protection**. Select an RMS template from the list, choose **Save**, and then choose **OK**.

   The list of templates includes default templates and options and any custom templates you create. If the list is empty, ensure that you have set up Office 365 Message Encryption with the new capabilities. For instructions, see Set up new Office 365 Message Encryption capabilities. For information about the default templates, see Configuring and managing templates for Azure Information Protection. For information about the **Do Not Forward** option, see Do Not Forward option for emails. For information about the **encrypt only** option, see Encrypt Only option for emails.

   Choose **add action** if you want to specify another action.

Background color reference

The color names that you can use for the background color are limited. Instead of a color name, you can use a hex code value (#RRGGBB). You can use a hex code value that corresponds to a color name, or you can use a custom hex code value. Be sure to enclose the hex code value in quotation marks (for example, `"#f0f8ff"`).

The available background color names and their corresponding hex code values are described in the following table.

COLOR NAME	COLOR CODE
`aliceblue`	#f0f8ff
`antiquewhite`	#faebd7
`aqua`	#00ffff
`aquamarine`	#7fffd4
`azure`	#f0ffff
`beige`	#f5f5dc
`bisque`	#ffe4c4

COLOR NAME	COLOR CODE

Create a sensitive information type policy for your organization using Message Encryption

11/2/2020 • 2 minutes to read • Edit Online

You can use either Exchange mail flow rules or Data Loss Prevention (DLP) to create a sensitive information type policy with Office 365 Message Encryption. To create an Exchange mail flow rule, you can use either the Exchange admin center (EAC) or PowerShell.

To create the policy by using mail flow rules in the EAC

Sign in to the Exchange admin center (EAC) and go to **Mail flow** > **Rules**. On the Rules page, create a rule that applies Office 365 Message Encryption. You can create a rule based on conditions such as the presence of certain keywords or sensitive information types in the message or attachment.

To create the policy by using mail flow rules in PowerShell

Use a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell. Use the Set-IRMConfiguration and New-TransportRule cmdlets to create the policy.

Example mail flow rule created with PowerShell

Run the following commands in PowerShell to create an Exchange mail flow rule that automatically encrypts emails sent outside your organization with the *Encrypt-Only* policy if the emails or their attachments contain the following sensitive information types:

- ABA routing number
- Credit card Number
- Drug Enforcement Agency (DEA) number
- U.S. / U.K. passport number
- U.S. bank account number
- U.S. Individual Taxpayer Identification Number (ITIN)
- U.S. Social Security Number (SSN)

```
Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $true
New-TransportRule -Name "Encrypt outbound sensitive emails (out of box rule)" -SentToScope
NotInOrganization  -ApplyRightsProtectionTemplate "Encrypt" -MessageContainsDataClassifications
@(@{Name="ABA Routing Number"; minCount="1"},@{Name="Credit Card Number"; minCount="1"},@{Name="Drug
Enforcement Agency (DEA) Number"; minCount="1"},@{Name="U.S. / U.K. Passport Number";
minCount="1"},@{Name="U.S. Bank Account Number"; minCount="1"},@{Name="U.S. Individual Taxpayer
Identification Number (ITIN)"; minCount="1"},@{Name="U.S. Social Security Number (SSN)"; minCount="1"}) -
SenderNotificationType "NotifyOnly"
```

For more information, see Set-IRMConfiguration and New-TransportRule.

How recipients access attachments

After Microsoft encrypts a message, recipients have unrestricted access to attachments when they access and open their encrypted email.

To prepare for this change

You may want to update any applicable end-user documentation and training materials to prepare people in your organization for this change. Share these Office 365 Message Encryption resources with your users as appropriate:

- Send, view, and reply to encrypted messages in Outlook for PC
- Microsoft 365 Essentials Video: Office Message Encryption

View these changes in the audit log

Microsoft 365 audits this activity and makes it available to administrators. The operation is 'New-TransportRule' and a snippet of a sample audit entry from the Audit Log Search in Security & Compliance Center is below:

```
*{"CreationTime":"2018-11-28T23:35:01","Id":"a1b2c3d4-daa0-4c4f-a019-03a1234a1b0c","Operation":"New-
TransportRule","OrganizationId":"123456-221d-12345
","RecordType":1,"ResultStatus":"True","UserKey":"Microsoft
Operator","UserType":3,"Version":1,"Workload":"Exchange","ClientIP":"123.456.147.68:17584","ObjectId":"","Us
erId":"Microsoft
Operator","ExternalAccess":true,"OrganizationName":"contoso.onmicrosoft.com","OriginatingServer":"CY4PR13MBX
XXX (15.20.1382.008)","Parameters": {"Name":"Organization","Value":"123456-221d-12346"
{"Name":"ApplyRightsProtectionTemplate","Value":"Encrypt"},{"Name":"Name","Value":"Encrypt outbound
sensitive emails (out of box rule)"},{"Name":"MessageContainsDataClassifications"…etc.*
```

To disable or customize the sensitive information types policy

Once you've created the Exchange mail flow rule, you can disable or edit the rule by going to **Mail flow** > **Rules** in the Exchange admin center (EAC) and disable the rule "*Encrypt outbound sensitive emails (out of box rule)*".

Manage Office 365 Message Encryption

11/2/2020 • 8 minutes to read • Edit Online

Once you've finished setting up Office 365 Message Encryption (OME), you can customize the configuration of your deployment in several ways. For example, you can configure whether to enable one-time pass codes, display the **Encrypt** button in Outlook on the web, and more. The tasks in this article describe how.

Manage whether Google, Yahoo, and Microsoft Account recipients can use these accounts to sign in to the Office 365 Message Encryption portal

When you set up the new Office 365 Message Encryption capabilities, users in your organization can send messages to recipients that are outside of your organization. If the recipient uses a *social ID* such as a Google account, Yahoo account, or Microsoft account, the recipient can sign in to the OME portal with a social ID. If you want, you can choose not to allow recipients to use social IDs to sign in to the OME portal.

To manage whether recipients can use social IDs to sign in to the OME portal

1. Connect to Exchange Online Using Remote PowerShell.
2. Run the Set-OMEConfiguration cmdlet with the SocialIdSignIn parameter as follows:

```
Set-OMEConfiguration -Identity <"OMEConfigurationIdParameter"> -SocialIdSignIn <$true|$false>
```

   For example, to disable social IDs:

```
Set-OMEConfiguration -Identity "OME Configuration" -SocialIdSignIn $false
```

   To enable social IDs:

```
Set-OMEConfiguration -Identity "OME Configuration" -SocialIdSignIn $true
```

Manage the use of one-time pass codes for the Office 365 Message Encryption portal

If the recipient of a message encrypted by OME doesn't use Outlook, regardless of the account used by the recipient, the recipient receives a limited-time web-view link that lets them read the message. This link includes a one-time pass code. As an administrator, you can decide if recipients can use one-time pass codes to sign in to the OME portal.

To manage whether OME generates one-time pass codes

1. Use a work or school account that has global administrator permissions in your organization and start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Run the Set-OMEConfiguration cmdlet with the OTPEnabled parameter:

```
Set-OMEConfiguration -Identity <"OMEConfigurationIdParameter "> -OTPEnabled <$true|$false>
```

For example, to disable one-time pass codes:

```
Set-OMEConfiguration -Identity "OME Configuration" -OTPEnabled $false
```

To enable one-time pass codes:

```
Set-OMEConfiguration -Identity "OME Configuration" -OTPEnabled $true
```

Manage the display of the Encrypt button in Outlook on the web

As an administrator, you can manage whether to display this button to end users.

To manage whether the Encrypt button appears in Outlook on the web

1. Use a work or school account that has global administrator permissions in your organization and start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. Run the Set-IRMConfiguration cmdlet with the -SimplifiedClientAccessEnabled parameter:

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled <$true|$false>
   ```

   For example, to disable the **Encrypt** button:

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $false
   ```

   To enable the **Encrypt** button:

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $true
   ```

Enable service-side decryption of email messages for iOS mail app users

The iOS mail app can't decrypt messages protected with Office 365 Message Encryption. As a Microsoft 365 administrator, you can apply service-side decryption for messages delivered to the iOS mail app. When you choose to do use service-side decryption, the service sends a decrypted copy of the message to the iOS device. The client device stores a decrypted copy of the message. The message also retains information about usage rights even though the iOS mail app doesn't apply client-side usage rights to the user. The user can copy or print the message even if they didn't originally have the rights to do so. However, if the user attempts to complete an action that requires the Microsoft 365 mail server, such as forwarding the message, the server won't permit the action if the user didn't originally have the usage right to do so. However, end users can work around "Do Not Forward" usage restriction by forwarding the message from a different account within the iOS mail app. Regardless of whether you set up service-side decryption of mail, attachments to encrypted and rights protected mail can't be viewed in the iOS mail app.

If you choose not to allow decrypted messages to be sent to iOS mail app users, users receive a message that states that they don't have the rights to view the message. By default, service-side decryption of email messages is not enabled.

For more information, and for a view of the client experience, see View encrypted messages on your iPhone or iPad.

To manage whether iOS mail app users can view messages protected by Office 365 Message Encryption

1. Use a work or school account that has global administrator permissions in your organization and start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-ActiveSyncOrganizations cmdlet with the AllowRMSSupportForUnenlightenedApps parameter:

   ```
   Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps <$true|$false>
   ```

   For example, to configure the service to decrypt messages before they're sent to unenlightened apps like the iOS mail app:

   ```
   Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps $true
   ```

   Or, to configure the service not to send decrypted messages to unenlightened apps:

   ```
   Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps $false
   ```

> **NOTE**
> Individual mailbox policies (OWA/ActiveSync) override these settings (i.e. if -IRMEnabled is set to False within the respective OWA Mailbox policy, or ActiveSync Mailbox policy, then these configurations would not apply).

Enable service-side decryption of email attachments for web browser mail clients

Normally, when you use Office 365 message encryption, attachments are automatically encrypted. As an administrator, you can apply service-side decryption for email attachments that users download from a web browser.

When you use service-side decryption, the service sends a decrypted copy of the file to the device. The message is still encrypted. The email attachment also keeps information about usage rights even though the browser doesn't apply client-side usage rights to the user. The user can copy or print the email attachment even if they didn't originally have the rights to do so. However, if the user tries to complete an action that requires the Microsoft 365 mail server, such as forwarding the attachment, the server won't permit the action if the user didn't originally have the usage right to do so.

Regardless of whether you set up service-side decryption of attachments, users can't view any attachments to encrypted and rights protected mail in the iOS mail app.

If you choose not to allow decrypted email attachments, which is the default, users receive a message that states that they don't have the rights to view the attachment.

For more information about how Microsoft 365 implements encryption for emails and email attachments with the Encrypt-Only option, see Encrypt-Only option for emails.

To manage whether email attachments are decrypted on download from a web browser

1. Use a work or school account that has global administrator permissions in your organization and start a

Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-IRMConfiguration cmdlet with the DecryptAttachmentForEncryptOnly parameter:

```
Set-IRMConfiguration -DecryptAttachmentForEncryptOnly <$true|$false>
```

For example, to configure the service to decrypt email attachments when a user downloads them from a web browser:

```
Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $true
```

To configure the service to leave encrypted email attachments as they are upon download:

```
Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $false
```

Ensure all external recipients use the OME Portal to read encrypted mail

You can use custom branding templates to force recipients to receive a wrapper mail that directs them to read encrypted email in the OME Portal instead of using Outlook or Outlook on the web. You might want to do this if you use want greater control over how recipients use the mail they receive. For example, if external recipients view email in the web portal, you can set an expiration date for the email, and you can revoke the email. These features are only supported through the OME Portal. You can use the Encrypt option and the Do Not Forward option when creating the mail flow rules.

Use a custom template to force all external recipients to use the OME Portal and for encrypted email

1. Use a work or school account that has global administrator permissions in your organization and start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the New-TransportRule cmdlet:

```
New-TransportRule -name "<mail flow rule name>" -FromScope "InOrganization" -
ApplyRightsProtectionTemplate "<option name>" -ApplyRightsProtectionCustomizationTemplate "<template
name>"
```

where:

- `mail flow rule name` is the name you want to use for the new mail flow rule.
- `option name` is either `Encrypt` or `Do Not Forward`.
- `template name` is the name you gave the custom branding template, for example `OME Configuration`.

To encrypt all external email with the "OME Configuration" template and apply the Encrypt-Only option:

```
New-TransportRule -name "<All outgoing mail>" -FromScope "InOrganization" -
ApplyRightsProtectionTemplate "Encrypt" -ApplyRightsProtectionCustomizationTemplate "OME
Configuration"
```

To encrypt all external email with the "OME Configuration" template and apply the Do Not Forward

option:

```
New-TransportRule -name "<All outgoing mail>" -FromScope "InOrganization" -
ApplyRightsProtectionTemplate "Do Not Forward" -ApplyRightsProtectionCustomizationTemplate "OME
Configuration"
```

Customize the appearance of email messages and the OME portal

For detailed information about how you can customize OME for your organization, see Add your organization's brand to your encrypted messages.

Disable the new capabilities for OME

We hope it doesn't come to it, but if you need to, disabling the new capabilities for OME is very straightforward. First, you'll need to remove any mail flow rules you've created that use the new OME capabilities. For information about removing mail flow rules, see Manage mail flow rules. Then, complete these steps in Exchange Online PowerShell.

To disable the new capabilities for OME

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.
2. If you enabled the **Encrypt** button in Outlook on the web, disable it by running the Set-IRMConfiguration cmdlet with the SimplifiedClientAccessEnabled parameter. Otherwise, skip this step.

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $false
   ```

3. Disable the new capabilities for OME by running the Set-IRMConfiguration cmdlet with the AzureRMSLicensingEnabled parameter set to false:

   ```
   Set-IRMConfiguration -AzureRMSLicensingEnabled $false
   ```

Advanced Message Encryption

4/21/2020 • 2 minutes to read • Edit Online

Office 365 Advanced Message Encryption is included in Microsoft 365 Enterprise E5, Office 365 E5, Microsoft 365 E5 (Nonprofit Staff Pricing), Office 365 Enterprise E5 (Nonprofit Staff Pricing), and Office 365 Education A5. If your organization has a subscription that does not include Office 365 Advanced Message Encryption, you can purchase it with the Microsoft 365 E5 Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), or the Office 365 Advanced Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), Office 365 SKUs, or the Microsoft 365 E5/A5 Information Protection and Governance SKU add-on for Microsoft 365 A3/E3.

Advanced Message Encryption helps customers meet compliance obligations that require more flexible controls over external recipients and their access to encrypted emails. With Advanced Message Encryption in Office 365, you can control sensitive emails shared outside the organization with automatic policies. You configure these policies to identify sensitive information types such as PII, Financial, or Health IDs, or you can use keywords to enhance protection. Once you've configured the policies, you pair policies with custom branded email templates and then add an expiration date for extra control of emails that fit the policy. Also, admins can further control encrypted emails accessed externally through a secure web portal by revoking access to the mail at any time.

You can only revoke and set an expiration date for emails sent to external recipients.

Get started with Office 365 Advanced Message Encryption

The following articles describe how you set up and use Advanced Message Encryption.

Your organization must have a subscription that includes Office 365 Advanced Message Encryption. For detailed information about supported subscriptions, see the Message policy and compliance service description.

If you do not have Office 365 Message Encryption set up already, see Set up new Office 365 Message Encryption capabilities.

With Advanced Message Encryption you're not limited to a single branding template. Instead, you can create and use multiple branding templates. For information, see Add your organization's brand to your encrypted messages.

Set an expiration date for email encrypted by Office 365 Advanced Message Encryption. Control sensitive emails shared outside the organization with automatic policies that enhance protection by expiring access through a secure web portal to encrypted emails.

Revoke email encrypted by Office 365 Advanced Message Encryption. Control sensitive emails shared outside the organization and enhance protection by revoking access through a secure web portal to encrypted emails.

With Office 365 Advanced Message Encryption, anytime you apply a custom branding template, Microsoft applies a wrapper to email that fits the mail flow rule to which you apply the template. You can only revoke messages and apply expiration dates to messages that users receive through the portal. In other words, email that has a custom branding template applied. For more information and an example, see the guidance in Ensure all external recipients use the OME Portal to read encrypted mail.

Set an expiration date for email encrypted by Office 365 Advanced Message Encryption

11/2/2020 • 2 minutes to read • Edit Online

Office 365 Advanced Message Encryption is included in Microsoft 365 Enterprise E5, Office 365 E5, Microsoft 365 E5 (Nonprofit Staff Pricing), Office 365 Enterprise E5 (Nonprofit Staff Pricing), and Office 365 Education A5. If your organization has a subscription that does not include Office 365 Advanced Message Encryption, you can purchase it with the Microsoft 365 E5 Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), or the Office 365 Advanced Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), or Office 365 SKUs.

You can use message expiration on emails that your users send to external recipients who use the OME Portal to access encrypted emails. You force recipients to use the OME portal to view and reply to encrypted emails sent by your organization by using a custom branded template that specifies an expiration date in Windows PowerShell.

As an Office 365 global administrator, when you apply your company brand to customize the look of your organization's email messages, you can also specify an expiration for these email messages. With Office 365 Advanced Message Encryption, you can create multiple templates for encrypted emails that originate from your organization. Using a template, you can control how long recipients have access to mail sent by your users.

When an end user receives mail that has an expiration date set, the user sees the expiration date in the wrapper email. If a user tries to open an expired mail, an error appears in the OME portal.

You can only set expiration dates for emails to external recipients.

With Office 365 Advanced Message Encryption, anytime you apply custom branding, the Office 365 applies the wrapper to email that fits the mail flow rule to which you apply the template. In addition, you can only use expiration if you use custom branding.

Create a custom branding template to force mail expiration by using PowerShell

1. Connect to Exchange Online PowerShell with an account that has global administrator permissions in your organization.
2. Run the New-OMEConfiguration cmdlet.

```
New-OMEConfiguration -Identity "Expire in 7 days" -ExternalMailExpiryInDays 7
```

Where:

- `Identity` is the name of the custom template.
- `ExternalMailExpiryInDays` identifies the number of days that recipients can keep mail before it expires. You can use any value between 1–730 days.

More information about Office 365 Advanced Message Encryption

- Office 365 Advanced Message Encryption

- Revoke email encrypted by Office 365 Advanced Message Encryption
- Message policy and compliance service description

Revoke email encrypted by Advanced Message Encryption

2/18/2021 • 5 minutes to read • Edit Online

Email revocation is offered as part of Office 365 Advanced Message Encryption. Office 365 Advanced Message Encryption is included in Microsoft 365 Enterprise E5, Office 365 E5, Microsoft 365 E5 (Nonprofit Staff Pricing), Office 365 Enterprise E5 (Nonprofit Staff Pricing), and Office 365 Education A5. If your organization has a subscription that does not include Office 365 Advanced Message Encryption, you can purchase it with the Microsoft 365 E5 Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), or the Office 365 Advanced Compliance SKU add-on for Microsoft 365 E3, Microsoft 365 E3 (Nonprofit Staff Pricing), or Office 365 SKUs.

This article is part of a larger series of articles about Office 365 Message Encryption.

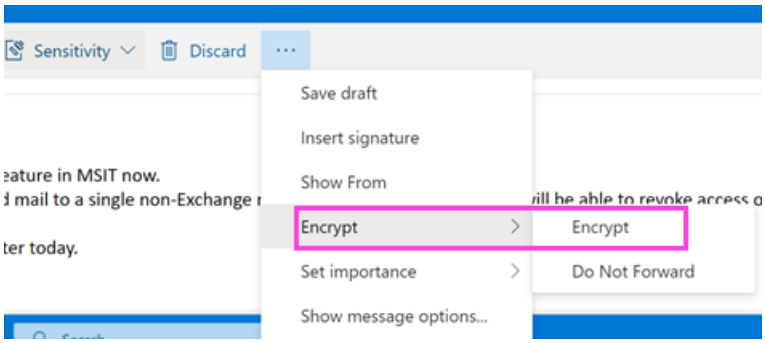
If a message was encrypted using Office 365 Advanced Message Encryption, and you are a Microsoft 365 admin or you are the sender of the message, you can revoke the message under certain conditions. Admins revoke messages using PowerShell. As a sender, you revoke a message that you sent directly from Outlook on the web. This article describes the circumstances under which revocation is possible and how to do it.

Encrypted emails that you can revoke

Admins and message senders can revoke encrypted emails if the recipient received a link-based, branded encrypted email. If the recipient received a native inline experience in a supported Outlook client, then you can't revoke the message.

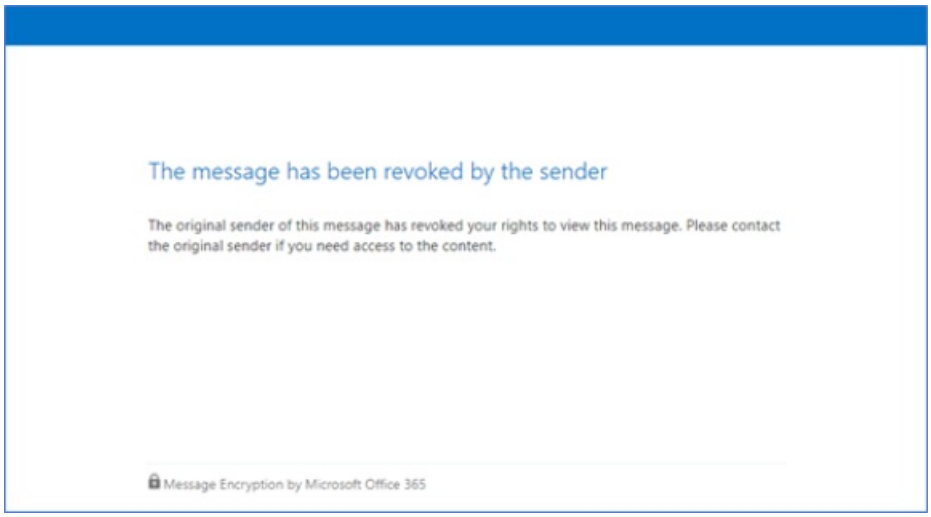
Whether a recipient receives a link-based experience or an inline experience depends on the recipient identity type: Office 365 and Microsoft account recipients (for example, outlook.com users) get an inline experience in supported Outlook clients. All other recipient types, such as Gmail and Yahoo recipients, get a link-based experience.

Admins and message senders can revoke messages that are encrypted using encryption applied directly from Outlook on the web. For example, messages encrypted with the Encrypt Only option.



Recipient experience for revoked encrypted emails

Once an email has been revoked, the recipient receives an error when they access the encrypted email through the Office 365 Message Encryption portal: "The message has been revoked by the sender".



How to revoke an encrypted message that you sent

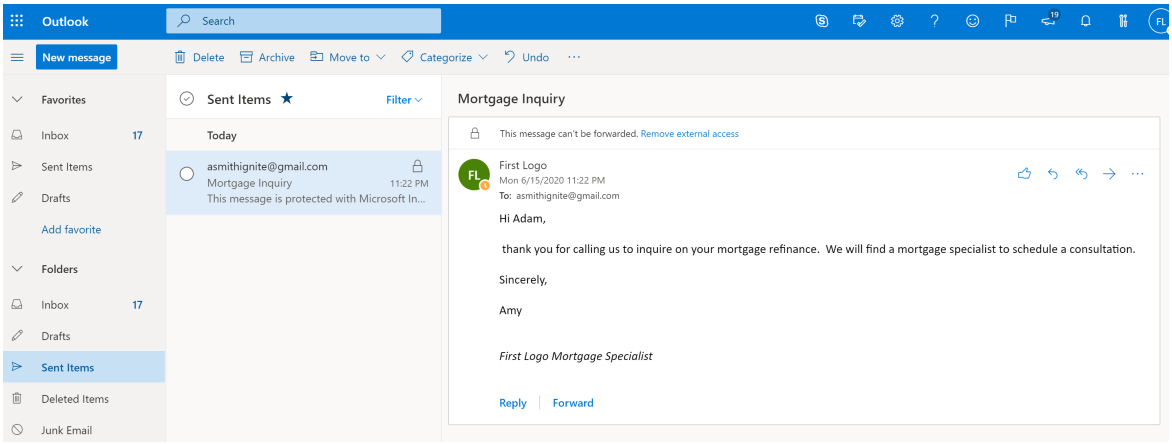
You can revoke a mail that you sent to a single recipient that uses a social account such as gmail.com or yahoo.com. In other words, you can revoke an email sent to a single recipient that received the link-based experience.

You cannot revoke a mail that you sent to a recipient that uses a work or school account from Office 365 or Microsoft 365 or a user that uses a Microsoft account, for example, an outlook.com account.

To revoke an encrypted message that you sent, complete these steps

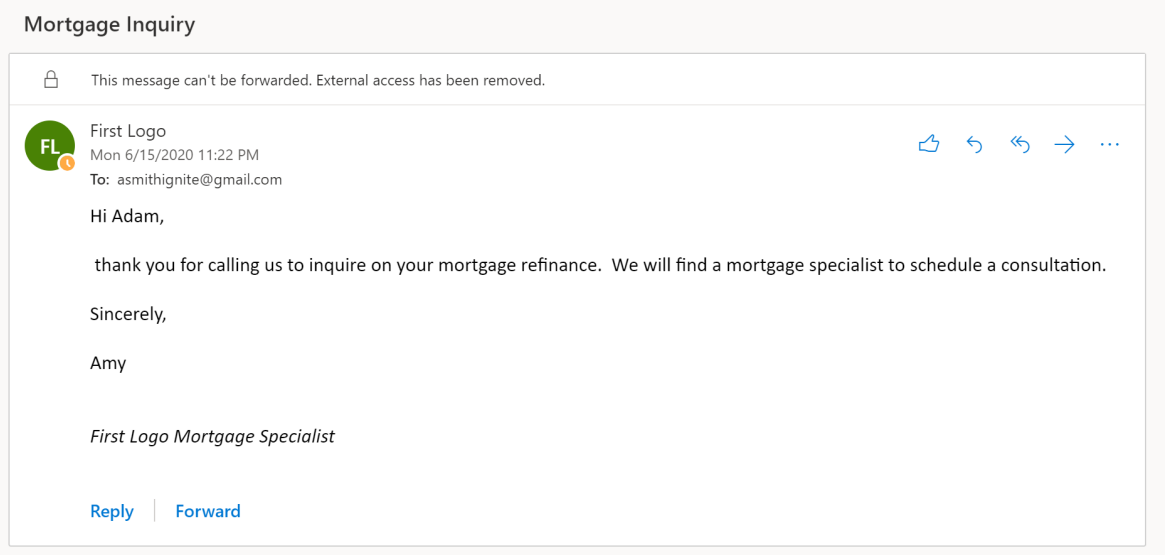
1. In Outlook on the web, in your **Sent** folder, browse to the message you want to revoke.

   If the mail is revocable, you'll see the "Remove external access" link at the top of the message.



2. Click **Remove external access** to revoke the message.

   The message shows that its status is revoked.



How to revoke an encrypted message as an administrator

Microsoft 365 administrators follow these general steps to revoke an eligible encrypted email:

- Get the Message ID of the email.
- Verify that you can revoke the message.
- Revoke the mail.

Step 1. Obtain the Message ID of the email

Before you can revoke an encrypted mail, gather the Message ID of the mail. The MessageId is usually of the format:

```
<xxxxxxxxxxxxxxxxxxxxxxx@xxxxxx.xxxx.prod.outlook.com>
```

There are multiple ways to find the Message ID of the email that you want to revoke. This section describes a couple of options, but you can use any method that provides the ID.

To identify the Message ID of the email you want to revoke by using Message Trace in the Security & Compliance Center

1. Search for the email by sender or recipient using New Message Trace in Security & Compliance Center.
2. Once you've located the email, select it to bring up the **Message trace details** pane. Expand **More Information** to locate the Message ID.

To identify the Message ID of the email you want to revoke by using Office Message Encryption reports in the Security & Compliance Center

1. In the Security & Compliance Center, navigate to the **Message encryption report**. For information on this report, see View email security reports in the Security & Compliance Center.
2. Choose the **View details** table and identify the message that you want to revoke.
3. Double-click the message to view details that include the Message ID.

Step 2. Verify that the mail is revocable

To verify whether you can revoke a message, check whether the Revocation Status field is visible in the Encryption report, in the **Details** table in the Security & Compliance Center.

To verify whether you can revoke a particular email message by using Windows PowerShell, complete these steps.

1. Using a work or school account that has global administrator permissions in your organization, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Get-OMEMessageStatus cmdlet as follows:

```
Get-OMEMessageStatus -MessageId "<message id>" | ft -a  Subject, IsRevocable
```

   This command returns the subject of the message and whether the message is revocable. For example,

```
Subject        IsRevocable
-------        -----------
"Test message"True
```

Step 3. Revoke the mail

Once you know the Message ID of the email you want to revoke, and you have verified that the message is revocable, you can revoke the email using the Security & Compliance Center or Windows PowerShell.

To revoke the message using the Security & Compliance Center

1. Using a work or school account that has global administrator permissions in your organization, connect to the Security & Compliance Center.
2. In the **Encryption report**, in the **Details** table for the message, choose **Revoke message**.

To revoke an email by using Windows PowerShell, use the Set-OMEMessageRevocation cmdlet.

1. Using a work or school account that has global administrator permissions in your organization, Connect to Exchange Online PowerShell.
2. Run the Set-OMEMessageRevocation cmdlet as follows:

```
Set-OMEMessageRevocation -Revoke $true -MessageId "<messageId>"
```

3. To check whether the email was revoked, run the Get-OMEMessageStatus cmdlet as follows:

```
Get-OMEMessageStatus -MessageId "<messageId>" | ft -a  Subject, Revoked
```

   If revocation was successful, the cmdlet returns the following result:

```
Revoked: True
```

Compare versions of OME

2/18/2021 • 7 minutes to read • Edit Online

> **IMPORTANT**
> On February 28, 2021, Microsoft will deprecate support for AD RMS in Exchange Online. If you've deployed a hybrid environment where your Exchange mailboxes are online and you're using IRM with Active Directory RMS on-premises, you'll need to migrate to Azure. Organizations that have deployed into the GCC Moderate environment are also affected. See "Overview of AD RMS deprecation in Exchange Online" in this article for information.

The rest of this article compares legacy Office 365 Message Encryption (OME) to the new OME capabilities and Office 365 Advanced Message Encryption. The new capabilities are a merger and newer version of both OME and Information Rights Management (IRM). Unique characteristics of deploying into GCC High are also outlined. The two can coexist in your organization. For information on how the new capabilities work, see Office 365 Message Encryption (OME).

This article is part of a larger series of articles about Office 365 Message Encryption. This article is intended for administrators and ITPros. If you're just looking for information on sending or receiving an encrypted message, see the list of articles in Office 365 Message Encryption (OME) and locate the article that best fits your needs.

Overview of AD RMS deprecation in Exchange Online

Exchange Online includes Information Rights Management (IRM) functionality that provides online and offline protection of email messages and attachments. By default, Exchange Online uses Azure Azure Information Protection. However, your organization may have configured Exchange Online IRM to use on-premises Active Directory Rights Management Service (AD RMS). AD RMS support in Exchange Online is retiring. Instead, Azure Information Protection will replace AD RMS entirely.

Before you begin, review and assess the impact for your organization. If your organization is already using Azure Information Protection to encrypt email in Exchange Online, there is nothing for you to do. If you encrypt your email using Exchange mail flow rules, for example using Office 365 Message Encryption, you won't have to change your secure email. Otherwise, you'll need to prepare for AD RMS deprecation by switching to Azure Information Protection.

Prepare for AD RMS deprecation

If you've already set up Azure Information Protection but you're not using it, enable the service using Exchange Online PowerShell. On your local computer, using a work or school account that has global administrator permissions in your organization, connect to Exchange Online PowerShell in a Windows PowerShell window.

To enable Azure Information Protection, use the Set-IrmConfiguration cmdlet by typing the following command.

```
Set-IrmConfiguration -AzureRMSLicensingEnabled $true
```

If your organization has not yet set up Azure Information Protection, you'll need to migrate from AD RMS to Azure Information Protection. For instructions, see Migrating from AD RMS to Azure Information Protection.

Side-by-side comparison of features and capabilities

SITUATION	LEGACY OME	IRM IN AD RMS	NEW OME CAPABILITIES
Sending an encrypted mail	Through Exchange mail flow rules	End-user initiated from Outlook desktop or Outlook on the Web; or through Exchange mail flow rules	End-user initiated from Outlook desktop, Outlook for Mac, or Outlook on the Web; through Exchange mail flow rules (also known as transport rules) and Data Loss Prevention (DLP)
Rights management template	N/A	Do Not Forward option and custom templates	Do Not Forward option, Encrypt-Only option, and custom templates
Recipient type	Internal and external recipients	Internal recipients only	Internal and external recipients
Experience for internal recipient	Recipients receive an HTML message, which they download and open in a web browser or mobile app	Native inline experience in Outlook clients	Native inline experience for recipients in the same organization using Outlook clients. Recipients can read message from OME portal using clients other than Outlook (no download or app required).
Experience for external recipient	Recipients receive an HTML message, which they download and open in a web browser or mobile app	N/A	Native inline experience for Microsoft 365 recipients. All other recipients can read message from OME portal (no download or app required).
Attachment permissions	No restrictions on attachments	Attachments are protected	Attachments are protected for the Do Not Forward option and custom templates. Admins can choose whether attachments for the Encrypt-Only option are protected or not.
Bring your own key (BYOK) support	None	None	BYOK supported

Advantages of the new OME capabilities over legacy OME

The new capabilities provide the following advantages:

- Ability to use Encrypt-Only (which enables secure collaboration), Do Not Forward, and custom restrictions.
- Senders can send mail encrypted with the new capabilities manually from Outlook Desktop, Outlook for Mac and Outlook on the web clients.
- Microsoft 365 recipients get to use an inline experience in supported Outlook clients. Alternatively, admins can choose to show Microsoft 365 recipients a branded experience.
- Accounts outside of Microsoft 365, such as Gmail, Yahoo, and Microsoft accounts, are federated with the OME portal, which provides a better user experience for these recipients. All other identities use a one-time

pass code to access encrypted messages.

- Admins can customize branding, and create multiple branding templates.
- Admins can revoke emails encrypted with the new capabilities.
- The new capabilities provide detailed usage reports through the Security & Compliance Center.

Office 365 Advanced Message Encryption capabilities

Office 365 Advanced Message Encryption offers additional capabilities on top of the new OME capabilities. You must have the new Office 365 Message Encryption capabilities set up in your organization in order to use the Advanced Message Encryption capabilities. Also, in order to use these capabilities, recipients must view and reply to secure mail through the OME Portal. The advanced capabilities include:

- Message revocation
- Message expiration
- Multiple branding templates

Office 365 Advanced Message Encryption is not supported in GCC High.

For information on using Advanced Message Encryption, see Office 365 Advanced Message Encryption.

Unique characteristics of Office 365 Message Encryption in a GCC High deployment

If you plan to use Office 365 Message Encryption in a GCC High environment, there are some unique characteristics regarding the recipient experience.

Encrypted email between GCC High and GCC High recipients

Senders can manually encrypt emails in Outlook for PC and Mac and Outlook on the web, or organizations can set up a policy to encrypt emails using Exchange mail flow rules.

Recipients inside GCC High receive the same inline reading experience in Outlook for PC and Mac and Outlook on the web as all other users.

Encrypted email between GCC High and Non-GCC High recipients

Senders inside GCC High can send encrypted email outside of the GCC High boundary and vice versa.

All recipients outside GCC High, including commercial Microsoft 365 users, Outlook.com users, and other users of other email providers such as Gmail and Yahoo, receive a wrapper mail. This wrapper mail redirects the recipient to the OME Portal where the recipient can read and reply to the message. This is also true for senders outside GCC High sending OME encrypted mail to GCC High.

Coexistence of legacy OME and the new capabilities in the same tenant

You can use both legacy OME and the new capabilities in the same tenant. As an administrator, you do this by choosing which version of OME you want to use when you create your mail flow rules.

- To specify the legacy version of OME, use the Exchange mail flow rule action **Apply the previous version of OME**.
- To specify the new capabilities, use the Exchange mail flow rule action **Apply Office 365 Message Encryption and rights protection**.

Users can manually send mail that is encrypted with the new capabilities from Outlook Desktop, Outlook for

Mac, and Outlook on the web.

Migrate from legacy OME to the new capabilities

Even though both versions of OME can coexist, we highly recommend that you edit your old mail flow rules that use the rule action **Apply the previous version of OME** to use the new capabilities. Update these rules to use the mail flow rule action **Apply Office 365 Message Encryption and rights protection**. For instructions, see Define mail flow rules to encrypt email messages in Office 365.

Get started with OME

Typically, the new OME capabilities are automatically enabled for your organization. For more information about the new OME capabilities within your organization, see Set up new Office 365 Message Encryption capabilities.

The legacy version of OME is automatically enabled for your organization if you have enabled Azure Information Protection. In the past, legacy OME worked even if Azure Information Protection wasn't enabled. This is no longer the case.

To start using legacy OME, if you have enabled Azure Information Protection, configure mail flow rules that use the rule action **Apply the previous version of OME**. For instructions, see Define mail flow rules to encrypt email messages.

Message Encryption FAQ

2/18/2021 • 11 minutes to read • Edit Online

Have a question about how the new message protection capabilities work? Check for an answer here. Also, take a look at Frequently asked questions about data protection in Azure Information Protection for answers to questions about the data protection service, Azure Rights Management, in Azure Information Protection.

What is Office 365 Message Encryption (OME)?

OME combines email encryption and rights management capabilities. Rights management capabilities are powered by Azure Information Protection.

Who can use OME?

You can use the new capabilities for OME under the following conditions:

- If you have never set up OME or IRM for Exchange Online in Office 365.
- If you have set up OME and IRM, you can use these steps if you are using the Azure Rights Management service from Azure Information Protection.
- If you are using Exchange Online with Active Directory Rights Management service (AD RMS), you can't enable these new capabilities right away. Instead, you need to migrate AD RMS to Azure Information Protection first. When you've finished the migration, you can successfully set up OME.

  If you choose to continue to use on-premises AD RMS with Exchange Online instead of migrating to Azure Information Protection, you will not be able to use these new capabilities.

What subscriptions do I need to use the new OME capabilities?

To use the new OME capabilities, you need one of the following plans:

- Office 365 Message Encryption is offered as part of Office 365 Enterprise E3 and E5, Microsoft Enterprise E3 and E5, Microsoft 365 Business Premium, Office 365 A1, A3, and A5, and Office 365 Government G3 and G5. Customers do not need additional licenses to receive the new protection capabilities powered by Azure Information Protection.
- You can also add Azure Information Protection Plan 1 to the following plans to receive the new Office 365 Message Encryption capabilities: Exchange Online Plan 1, Exchange Online Plan 2, Office 365 F1, Microsoft 365 Business Basic, Microsoft 365 Business Standard, or Office 365 Enterprise E1.
- Each user benefiting from Office 365 Message Encryption needs to be licensed to be covered by the feature.
- For the full list see the Exchange Online service descriptions for Office 365 Message Encryption.

Can I use Exchange Online with bring your own key (BYOK) in Azure Information Protection?

Yes! Microsoft recommends that you complete the steps to set up BYOK before you set up OME.

For more information about BYOK, see Planning and implementing your Azure Information Protection tenant key.

Do OME and BYOK with Azure Information Protection change Microsoft's approach to third-party data requests such as subpoenas?

No. OME and the option to provide and control your own encryption keys, called BYOK, from Azure Information Protection were not designed to respond to law enforcement subpoenas. OME, with BYOK for Azure Information Protection, was designed for compliance-focused customers. Microsoft takes third-party requests for customer data very seriously. As a cloud service provider, we always advocate for the privacy of customer data. In the event we get a subpoena, we always attempt to redirect the third party to the customer to obtain the information. (Please read Brad Smith's blog: Protecting customer data from government snooping). We periodically publish detailed information of the request we receive. For more information regarding third-party data requests, see Responding to government and law enforcement requests to access customer data on the Microsoft Trust Center. Also, see "Disclosure of Customer Data" in the Online Services Terms (OST).

How is this feature related to legacy Office 365 Message Encryption (OME) and Information Rights Management (IRM) features?

The new capabilities for Office 365 Message Encryption are an evolution of the existing IRM and legacy OME solutions. The following table provides more details.

Comparison of legacy OME, IRM, and new OME capabilities

CAPABILITY	PREVIOUS VERSIONS OF OME	IRM	NEW OME CAPABILITIES
Sending an encrypted email	Only through Exchange mail flow rules	End-user initiated from Outlook for Windows, Outlook for Mac, or Outlook on the web; or through Exchange mail flow rules	End-user initiated from Outlook for Windows, Outlook for Mac, or Outlook on the web; or through mail flow rules
Rights management	-	Do Not Forward option and custom templates	Do Not Forward option, encrypt-only option, default and custom templates
Supported recipient type	External recipients only	Internal recipients only	Internal and external recipients
Experience for recipient	External recipients received an HTML message that they downloaded and opened in a browser or downloaded mobile app.	Internal recipients only received encrypted email in Outlook for Windows, Outlook for Mac, and Outlook on the web.	Internal and external recipients receive email in Outlook for Windows, Outlook for Mac, Outlook on the web, Outlook for Android, and Outlook for iOS, or through a web portal, regardless of whether or not they are in the same organization or in any organization. The OME portal requires no separate download.
Bring Your Own Key support	Not available	Not available	BYOK supported

How do I enable the new OME capabilities for my organization?

See Set up new Office 365 Message Encryption capabilities.

Will the previous version of OME be deprecated?

You can still use the previous version of OME, it will not be deprecated at this time. However, we highly encourage organizations to use the new and improved OME solution. Customers that have not already deployed OME cannot set up a new deployment of the previous version of OME.

My organization uses Active Directory Rights Management, can I use this functionality?

No. If you are using Exchange Online with Active Directory Rights Management service (AD RMS), you can't enable these new capabilities right away. Instead, you need to migrate AD RMS to Azure Information Protection first.

My organization has an Exchange Hybrid deployment. Can I use this feature?

On-premises users can send encrypted mail using Exchange Online mail flow rules. In order to do this, you need to route email through Exchange Online. For more information, see Part 2: Configure mail to flow from your email server to Microsoft 365.

What email client do I need to use in order to create an OME encrypted message? What applications are supported for sending protected messages?

You can create protected messages from Outlook 2016, Outlook 2013 for Windows and Mac, and from Outlook on the web. For more information on sending encrypted messages, see Send, view, and reply to encrypted messages in Outlook for PC.

What email clients are supported to read and reply to protected emails?

Microsoft 365 users can read and respond from Outlook for Windows and Mac (2013 and 2016), Outlook on the web, and Outlook mobile (Android and iOS). You can also use the iOS native mail client if your organization allows it. If you are not a Microsoft 365 user, you can read and reply to encrypted messages on the web through your web browser.

What email clients support the encrypt-only protected emails?

Microsoft 365 users can use Outlook for PC versions 2019 and Microsoft 365 to create mail protected with the encrypt-only policy. That means messages that have the new encrypt-only policy applied can be read directly in Outlook on the web, in Outlook for iOS and Android, and now Outlook for PC versions 2019 and Microsoft 365.

Is there a size limit for messages you can send with OME?

Yes. The maximum message size you can send with OME, including attachments, is 25 MB. For more information, see Message limits.

What file types are supported as attachments in protected emails? Do attachments inherit the protection policies associated with protected

emails?

You can attach any file type to a protected mail. With one exception, protection policies are applied only on the file formats mentioned in File types supported by the Azure Information Protection client. OME does not support the 97-2003 versions of the following Office programs: Word (.doc), Excel (.xls), and PowerPoint (.ppt).

If a file format is supported, such as a Word, Excel, or PowerPoint file, the file is always protected, even after the attachment has been downloaded by the recipient. For example, say an attachment is protected by Do Not Forward. The original recipient downloads the file, creates a message to a new recipient and attaches the file. When the new recipient receives the file, the recipient will not be able to open the protected file.

Are PDF file attachments supported?

The short answer is yes! PDF encryption allows you to protect sensitive PDF documents through secure communication or secure collaboration. When you send email, the Office 365 service encrypts PDF file attachments not the Outlook client.

For Outlook on the web, Outlook for iOS, and Outlook for Android, you can encrypt PDFs you send without any additional steps. These clients natively support PDF encryption.

Outlook desktop does not natively support encryption of PDF file attachments. Instead, you'll need to set up Exchange mail flow rules or DLP to apply encryption to PDF attachments first. When you send mail from Outlook Desktop with a PDF attachment, the client sends the message with the attachment to the service first. When the service receives the file, the service applies the OME protection of the data loss prevention (DLP) policy or mail flow rule in Exchange Online. Next, Exchange Online sends the message with the protected PDF file attachment.

To enable encryption for PDF attachments, run the following command in Exchange Online PowerShell:

```
Set-IRMConfiguration -EnablePdfEncryption $true
```

PDF encryption allows you to protect sensitive PDF documents through secure communication or secure collaboration. For all Outlook clients, messages and unprotected PDF attachments inherit the OME protection of the data loss prevention (DLP) policy or mail flow rule in Exchange Online. Also, if an Outlook on the web user attaches an unprotected PDF document and applies protection to message, the message inherits the protection of the message. Users can only open the encrypted attachments in applications that support protected PDFs (for example, the OME Portal and the Azure Information Protection Viewer).

> **IMPORTANT**
> Outlook desktop client does not support PDF encryption.

Are OneDrive for Business attachments supported?

Not yet. OneDrive for Business attachments are not supported and end-users can't encrypt a mail that contains a cloud OneDrive for Business attachment.

What email clients support preview of encrypted attachments in protected emails?

When attachments are protected with a protected mail, Outlook clients provide tha ability to preview the document directly. Outlook supports preview of Office documents (docx, xlsx, pptx, doc, xls, ppt). Outlook on the web supports preview of Office documents (docx, xlsx, pptx) and PDF.

What email clients support revocation of protected emails?

Outlook on the web supports revocation of protected mail. See How to revoke an encrypted message that you sent for details.

Can I automatically encrypt messages by setting up policies?

Yes. Use mail flow rules in Exchange Online to automatically encrypt a message based on certain conditions. For example, you can create policies that are based on recipient ID, recipient domain, or on the content in the body or subject of the message. See Define mail flow rules to encrypt email messages in Office 365.

Can I automatically remove encryption on incoming and outgoing mail?

Admins can set up a mail flow rule to remove encryption for outgoing mail. You can't set up a rule to remove encryption for incoming mail.

Can I automatically encrypt messages by setting up policies in Data Loss Prevention (DLP) through the Security & Compliance Center?

Yes! You can set up mail flow rules in Exchange Online or by using DLP in the Security & Compliance Center.

Can I customize encrypted messages with my company branding?

Yes! For information on customizing email messages and the OME portal, see Add your organization's brand to your encrypted messages. See Add your organization's brand to your encrypted messages.

Are there any reporting capabilities or insights for encrypted emails?

There is an Encryption report in the Security and Compliance Center. See View email security reports in the Security & Compliance Center.

Can I use message encryption with compliance features such as eDiscovery?

Yes. All encrypted email messages are discoverable by Microsoft 365 compliance features.

Can I remove encryption from email?

Admins can set up a mail flow rule to remove encryption from outgoing mail. You can't remove encryption using a mail flow rule from incoming messages.

Is delegated access supported?

Not at this time.

Can I send as a shared mailbox and encrypt emails?

When someone sends an email message that matches an encryption mail flow rule, the message is encrypted before it's sent.

Can I open encrypted messages sent to a shared mailbox?

Yes! Encrypted messages are supported for a shared mailbox.

- Users can open protected mails in a shared mailbox where the shared mailbox received a protected mail as part of a distribution group.
- Users can view attachments that inherit protection from email when they use Outlook for Windows, Outlook for Mac, and Outlook on the web.

The following table lists the supported clients for shared mailboxes.

PLATFORM	READ MAIL	VIEW EMAIL ATTACHMENTS
Outlook on the web	Yes	Yes
Outlook for Windows	Yes	Yes
Outlook for Mac	Yes	Yes
Outlook for Android	Yes	No
Outlook for iOS	Yes	No

There are currently two known limitations:

- You can't open attachments to emails that you receive on mobile devices by using Outlook mobile.
- We don't support assignment through an email enabled security group. We only support access provided by direct user assignment to the shared mailbox and that automapping is enabled for Exchange Online. Automapping is enabled by default for Exchange Online.

To assign a user to the shared mailbox

1. Connect to Exchange Online Using Remote PowerShell.
2. Run the Add-MailboxPermission cmdlet with the Automapping parameter. This example gives Ayla full access permissions to a support mailbox.

```
Add-MailboxPermission -Identity support@contoso.onmicrosoft.com -User ayla@contoso.com -AccessRights
FullAccess -AutoMapping $true
```

Can I open encrypted messages sent to another user's mailbox with Fullaccess?

Users can open encrypted messages as long as they are given direct access and automapping is turned ON. Access is not allowed if the access is granted via an email-enabled security group.

What do I do if I don’t receive the one-time pass code after I requested it?

First, check the junk or spam folder in your email client. DKIM and DMARC settings for your organization may cause these emails to end up filtered as spam.

Next, check quarantine in the Security & Compliance Center. Often, messages containing a one-time pass code, especially the first ones your organization receives, end up in quarantine.

How Exchange Online secures your email secrets

4/21/2020 • 2 minutes to read • Edit Online

This article describes how Microsoft secures your email secrets in its datacenters.

How do we secure secret information provided by you?

In addition to the Office 365 Trust Center which provides Security, Privacy and Compliance Information for Office 365, you might want to know how Microsoft helps protects secrets you provide in its datacenters. We use a technology called Distributed Key Manager (DKM).

Distributed Key Manager (DKM) is a client-side functionality that uses a set of secret keys to encrypt and decrypt information. Only members of a specific security group in Active Directory Domain Services can access those keys in order to decrypt the data that is encrypted by DKM. In Exchange Online, only certain service accounts under which the Exchange processes run are part of that security group. As part of standard operating procedure in the datacenter, no human is given credentials that are part of this security group and therefore no human has access to the keys that can decrypt these secrets.

For debugging, troubleshooting, or auditing purposes, a datacenter administrator must request elevated access to gain temporary credentials that are part of the security group. This process requires multiple levels of legal approval. If access is granted, all activity is logged and audited. In addition access is only granted for a set interval of time after which it automatically expires.

For extra protection, DKM technology includes automated key rollover and archiving. This also ensures that you can continue to access your older content without having to rely on the same key indefinitely.

Where does Exchange Online make use of DKM?

Microsoft uses Distributed Key Manager to encrypt your secrets in Exchange Online datacenters. For example:

- Email account credentials for connected accounts. Connected accounts are third-party accounts such as Hotmail, Gmail, and Yahoo! mail accounts.
- Customer key. If you are using Service encryption with Customer Key, you'll use Azure Key Vault to safeguard your secrets.

How Exchange Online uses TLS to secure email connections

2/18/2021 • 6 minutes to read • Edit Online

Learn how Exchange Online and Microsoft 365 use Transport Layer Security (TLS) and Forward Secrecy (FS) to secure email communications. Also provides information about the certificate issued by Microsoft for Exchange Online.

TLS basics for Microsoft 365 and Exchange Online

Transport Layer Security (TLS), and SSL that came before TLS, are cryptographic protocols that secure communication over a network by using security certificates to encrypt a connection between computers. TLS supersedes Secure Sockets Layer (SSL) and is often referred to as SSL 3.1. For Exchange Online, we use TLS to encrypt the connections between our Exchange servers and the connections between our Exchange servers and other servers such as your on-premises Exchange servers or your recipients' mail servers. Once the connection is encrypted, all data sent through that connection is sent through the encrypted channel. However, if you forward a message that was sent through a TLS-encrypted connection, that message isn't necessarily encrypted. This is because, in simple terms, TLS doesn't encrypt the message, just the connection.

If you want to encrypt the message you need to use an encryption technology that encrypts the message contents, for example, something like Office Message Encryption. See Email encryption in Office 365 and Office 365 Message Encryption (OME) for information on message encryption options in Office 365.

We recommend using TLS in situations where you want to set up a secure channel of correspondence between Microsoft and your on-premises organization or another organization, such as a partner. Exchange Online always attempts to use TLS first to secure your email but cannot always do this if the other party does not offer TLS security. Keep reading to find out how you can secure all mail to your on-premises servers or important partners by using *connectors*.

To provide the best-in-class encryption to our customers, Microsoft has deprecated Transport Layer Security (TLS) versions 1.0 and 1.1 in Office 365 and Office 365 GCC. However, you can continue to use an unencrypted SMPT connection without any TLS. We don't recommend email transmission without any encryption.

How Exchange Online uses TLS between Exchange Online customers

Exchange Online servers always encrypt connections to other Exchange Online servers in our datacenters with TLS 1.2. When you send mail to a recipient that is within your organization, that email is automatically sent over a connection that is encrypted using TLS. Also, all email that you send to other customers is sent over connections that are encrypted using TLS and are secured using Forward Secrecy.

How Microsoft 365 uses TLS between Microsoft 365 and external, trusted partners

By default, Exchange Online always uses opportunistic TLS. This means Exchange Online always tries to encrypt connections with the most secure version of TLS first, then works its way down the list of TLS ciphers until it finds one on which both parties can agree. Unless you have configured Exchange Online to ensure that messages to that recipient are only sent through secure connections, then by default the message will be sent unencrypted if the recipient organization doesn't support TLS encryption. Opportunistic TLS is sufficient for most businesses. However, for business that have compliance requirements such as medical, banking, or

government organizations, you can configure Exchange Online to require, or force, TLS. For instructions, see Configure mail flow using connectors in Office 365.

If you decide to configure TLS between your organization and a trusted partner organization, Exchange Online can use forced TLS to create trusted channels of communication. Forced TLS requires your partner organization to authenticate to Exchange Online with a security certificate in order to send mail to you. Your partner will need to manage their own certificates in order to do this. In Exchange Online, we use connectors to protect messages that you send from unauthorized access before they arrive at the recipient's email provider. For information on using connectors to configure mail flow, see Configure mail flow using connectors in Office 365.

TLS and hybrid Exchange Server deployments

If you are managing a hybrid Exchange deployment, your on-premises Exchange server needs to authenticate to Microsoft 365 using a security certificate in order to send mail to recipients whose mailboxes are only in Office 365. As a result, you need to manage your own security certificates for your on-premises Exchange servers. You must also securely store and maintain these server certificates. For more information about managing certificates in hybrid deployments, see Certificate requirements for hybrid deployments.

How to set up forced TLS for Exchange Online in Office 365

For Exchange Online customers, in order for forced TLS to work to secure all of your sent and received email, you need to set up more than one connector that requires TLS. You'll need one connector for email sent to your user mailboxes and another connector for email sent from your user mailboxes. Create these connectors in the Exchange admin center in Office 365. For instructions, see Configure mail flow using connectors in Office 365.

TLS certificate information for Exchange Online

The certificate information used by Exchange Online is described in the following table. If your business partner is setting up forced TLS on their email server, you will need to provide this information to them. Be aware that for security reasons, our certificates do change from time to time. We have rolled out an update to our certificate within our datacenters. The new certificate is valid from September 3, 2018.

Current certificate information valid from September 3, 2018

ATTRIBUTE	VALUE
Certificate authority root issuer	GlobalSign Root CA – R1
Certificate name	mail.protection.outlook.com
Organization	Microsoft Corporation
Organization unit	
Certificate key strength	2048

Deprecated certificate information valid until September 3, 2018

To help ensure a smooth transition, we will continue to provide the old certificate information for your reference for some time, however, you should use the current certificate information from now on.

ATTRIBUTE	VALUE
Certificate authority root issuer	Baltimore CyberTrust Root
Certificate name	mail.protection.outlook.com
Organization	Microsoft Corporation
Organization unit	Microsoft Corporation
Certificate key strength	2048

Prepare for the new Exchange Online certificate

The new certificate is issued by a different certificate authority (CA) from the previous certificate used by Exchange Online. As a result, you may need to perform some actions in order to use the new certificate.

The new certificate requires connecting to the endpoints of the new CA as part of validating the certificate. Failure to do so can result in mail flow being negatively affected. If you protect your mail servers with firewalls that only let the mail servers connect with certain destinations you need to check if your server is able to validate the new certificate. To confirm that your server can use the new certificate, complete these steps:

1. Connect to your local Exchange Server using Windows PowerShell and then run the following command: `certutil -URL https://crl.globalsign.com/gsorganizationvalsha2g3.crl`
2. On the window that appears, choose **Retrieve**.
3. When the utility completes its check it returns a status. If the status displays **OK**, then your mail server can successfully validate the new certificate. If not, you need to determine what is causing the connections to fail. Most likely, you need to update the settings of a firewall. The full list of endpoints that need to be accessed include:
   - ocsp.globalsign.com
   - crl.globalsign.com
   - secure.globalsign.com

Normally, you receive updates to your root certificates automatically through Windows Update. However some deployments have additional security in place that prevents these updates from occurring automatically. In these locked-down deployments where Windows Update can't automatically update root certificates, you need to ensure that the correct root CA certificate is installed by completing these steps:

1. Connect to your local Exchange Server using Windows PowerShell and then run the following command: `certmgr.msc`
2. Under **Trusted Root Certification Authority/Certificates**, confirm that the new certificate is listed.

Get more information about TLS and Microsoft 365

For a list of supported cipher suites, see Technical reference details about encryption.

Set up connectors for secure mail flow with a partner organization

Connectors with enhanced email security

Encryption in Microsoft 365

BitLocker and Distributed Key Manager (DKM) for Encryption

5/5/2020 • 2 minutes to read • Edit Online

Microsoft servers use BitLocker to encrypt the disk drives containing customer data at rest at the volume-level. BitLocker encryption is a data protection feature that is built into Windows. BitLocker is one of the technologies used to safeguard against threats in case there are lapses in other processes or controls (e.g., access control or recycling of hardware) that could lead to someone gaining physical access to disks containing customer data. In this case, BitLocker eliminates the potential for data theft or exposure because of lost, stolen, or inappropriately decommissioned computers and disks.

BitLocker is deployed with Advanced Encryption Standard (AES) 256-bit encryption on disks containing customer data in Exchange Online, SharePoint Online, and Skype for Business. Disk sectors are encrypted with a Full Volume Encryption Key (FVEK), which is encrypted with the Volume Master Key (VMK), which in turn is bound to the Trusted Platform Module (TPM) in the server. The VMK directly protects the FVEK and therefore, protecting the VMK becomes critical. The following figure illustrates an example of the BitLocker key protection chain for a given server (in this case, using an Exchange Online server).

The following table describes the BitLocker key protection chain for a given server (in this case, an Exchange Online server).

KEY PROTECTOR	GRANULARITY	HOW GENERATED?	WHERE IS IT STORED?	PROTECTION
AES 256-bit External Key	Per Server	BitLocker APIs	TPM or Secret Safe	Lockbox / Access Control
			Mailbox Server Registry	TPM encrypted
48-digit Numerical Password	Per Disk	BitLocker APIs	Active Directory	Lockbox / Access Control
X.509 Certificate as Data Recovery Agent (DRA) also called Public Key Protector	Environment (e.g., Exchange Online multitenant)	Microsoft CA	Build System	No one user has the full password to the private key. The password is under physical protection.

BitLocker key management involves the management of recovery keys that are used to unlock/recover encrypted disks in a Microsoft datacenter. Microsoft 365 stores the master keys in a secured share, only accessible by individuals who have been screened and approved. The credentials for the keys are stored in a secured repository for access control data (what we call a "secret store"), which requires a high level of elevation and management approvals to access using a just-in-time access elevation tool.

BitLocker supports keys which fall into two management categories:

- BitLocker-managed keys, which are generally short-lived and tied to the lifetime of an operating system instance installed on a server or to a given disk. These keys are deleted and reset during server reinstallation or disk formatting.
- BitLocker recovery keys, which are managed outside of BitLocker but used for disk decryption. BitLocker

uses recovery keys for the scenario in which an operating system is reinstalled, and encrypted data disks already exist. Recovery keys are also used by Managed Availability monitoring probes in Exchange Online where a responder may need to unlock a disk.

BitLocker-protected volumes are encrypted with a full volume encryption key, which in turn is encrypted with a volume master key. BitLocker uses FIPS-compliant algorithms to ensure that encryption keys are never stored or sent over the wire in the clear. The Microsoft 365 implementation of customer data-at-rest-protection does not deviate from the default BitLocker implementation.

Legacy information for Office 365 Message Encryption

2/18/2021 • 17 minutes to read • Edit Online

If you haven't yet moved your organization to the new OME capabilities, but you have already deployed OME, then the information in this article applies to your organization. Microsoft recommends that you make a plan to move to the new OME capabilities as soon as it is reasonable for your organization. For instructions, see Set up new Office 365 Message Encryption capabilities built on top of Azure Information Protection. If you want to find out more about how the new capabilities work first, see Office 365 Message Encryption. The rest of this article refers to OME behavior before the release of the new OME capabilities.

With Office 365 Message Encryption, your organization can send and receive encrypted email messages between people inside and outside your organization. Office 365 Message Encryption works with Outlook.com, Yahoo, Gmail, and other email services. Email message encryption helps ensure that only intended recipients can view message content.

Here are some examples:

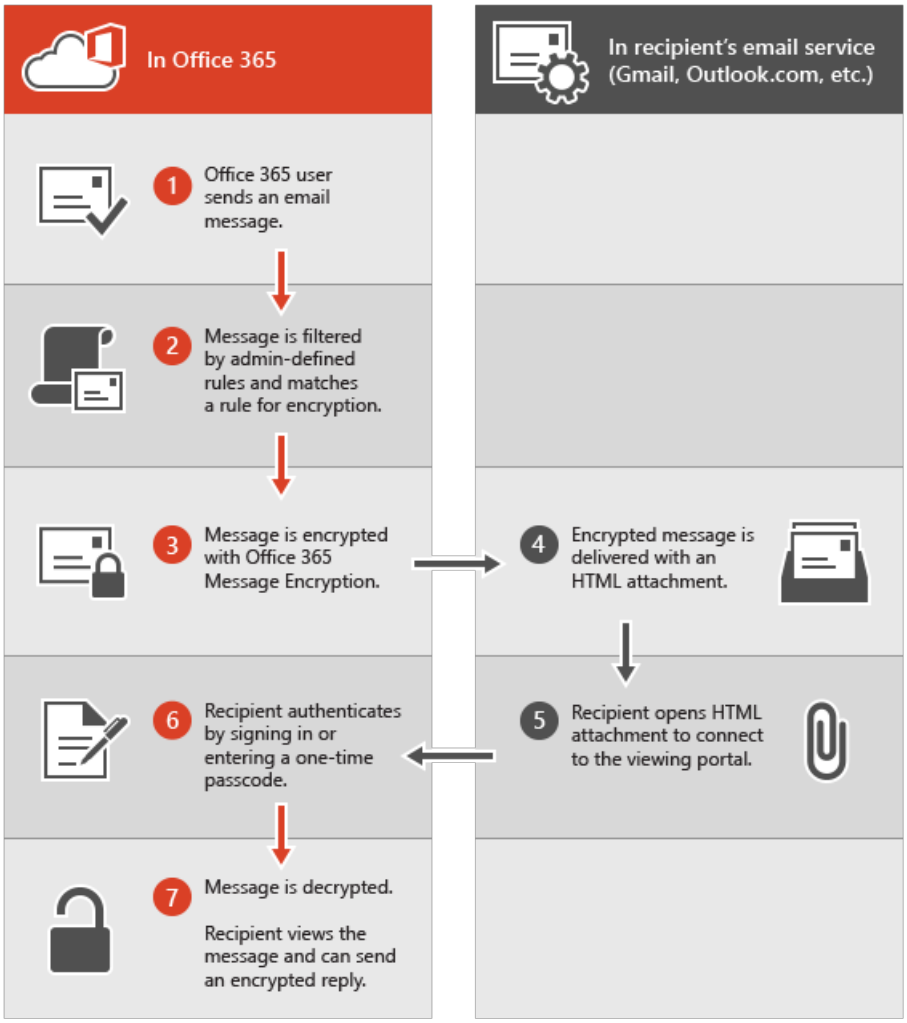
- A bank employee sends credit card statements to customers
- An insurance company representative provides policy details to customers
- A mortgage broker requests financial information from a customer for a loan application
- A health care provider sends health care information to patients
- An attorney sends confidential information to a customer or another attorney

How Office 365 Message Encryption works without the new capabilities

Office 365 Message Encryption is an online service that's built on Microsoft Azure Rights Management (Azure RMS). With Azure RMS, administrators can define mail flow rules to determine the conditions for encryption. For example, a rule can require the encryption of all messages addressed to a specific recipient.

When someone sends an email message in Exchange Online that matches an encryption rule, the message is sent with an HTML attachment. The recipient opens the HTML attachment and follows instructions to view the encrypted message on the Office 365 Message Encryption portal. The recipient can choose to view the message by signing in with a Microsoft account or a work or school associated with Office 365, or by using a one-time pass code. Both options help ensure that only the intended recipient can view the encrypted message. This process is very different for the new OME capabilities.

The following diagram summarizes the passage of an email message through the encryption and decryption process.



For more information, see Service information for legacy Office 365 Message Encryption prior to the release of the new OME capabilities.

Defining mail flow rules for Office 365 Message Encryption that don't use the new OME capabilities

To enable Office 365 Message Encryption without the new capabilities, Exchange Online and Exchange Online Protection administrators define Exchange mail flow rules. These rules determine under what conditions email messages should be encrypted, as well as conditions for removing message encryption. When an encryption action is set for a rule, the service performs the action on any messages that match the rule conditions before sending the messages.

Mail flow rules are flexible, letting you combine conditions so you can meet specific security requirements in a single rule. For example, you can create a rule to encrypt all messages that contain specified keywords and are addressed to external recipients. Office 365 Message Encryption also encrypts replies from recipients of encrypted email, and you can create a rule that decrypts those replies as a convenience for your email users. That way, users in your organization won't have to sign in to the encryption portal to view replies.

For more information about how to create Exchange mail flow rules, see Define Rules for Office 365 Message Encryption.

Use the EAC to create a mail flow rule for encrypting email messages without the new OME capabilities

1. In a web browser, using a work or school account that has been granted global administrator permissions, sign in to Office 365.
2. Choose the **Admin** tile.

3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Encrypt mail for DrToniRamos@hotmail.com.
6. In **Apply this rule if** select a condition, and enter a value if necessary. For example, to encrypt messages going to DrToniRamos@hotmail.com:
   a. In **Apply this rule if**, select **the recipient is**.
   b. Select an existing name from the contact list or type a new email address in the **check names** box.
      - To select an existing name, select it from the list and then click **OK**.
      - To enter a new name, type an email address in the **check names** box and then select **check names** > **OK**.
7. To add more conditions, choose **More options** and then select **add condition** and select from the list.

   For example, to apply the rule only if the recipient is outside your organization, select **add condition** and then select **The recipient is external/internal** > **Outside the organization** > **OK**.
8. To enable encryption without using the new OME capabilities, in **Do the following**, select **Modify the message security** > **Apply the previous version of OME**, and then choose **Save**.

   If you receive an error that IRM licensing isn't enabled, then you're not using legacy OME.
9. (Optional) Choose **add action** to specify another action.

Use Exchange Online PowerShell to create a mail flow rule for encrypting email messages without the new OME capabilities

1. Connect to Exchange Online PowerShell. For more information, see Connect to Exchange Online PowerShell.
2. Create a rule by using the **New-TransportRule** cmdlet and set the *ApplyOME* parameter to `$true`.

   This example requires that all email messages sent to DrToniRamos@hotmail.com must be encrypted.

   ```
   New-TransportRule -Name "Encrypt rule for Dr Toni Ramos" -SentTo "DrToniRamos@hotmail.com" -
   SentToScope "NotinOrganization" -ApplyOME $true
   ```

   Where,

   - The unique name of the new rule is "Encrypt rule for Dr Toni Ramos".
   - The *SentTo* parameter specifies the message recipients (identified by name, email address, distinguished name, etc.). In this example, the recipient is identified by the email address "DrToniRamos@hotmail.com".
   - The *SentToScope* parameter specifies the location of the message recipients. In this example, the recipient's mailbox is in hotmail and is not part of the organization, so the value `NotInOrganization` is used.

   For detailed syntax and parameter information, see New-TransportRule.

Remove encryption from email replies encrypted without the new OME capabilities

When your email users send encrypted messages, recipients of those messages can respond with encrypted replies. You can create mail flow rules to automatically remove encryption from replies so email users in your organization don't have to sign in to the encryption portal to view them. You can use the EAC or Windows PowerShell cmdlets to define these rules. You can decrypt messages that are sent from within your organization

or messages that are replies to messages sent from within your organization. You cannot decrypt encrypted messages originating from outside of your organization.

Use the EAC to create a rule for removing encryption from email replies encrypted without the new OME capabilities

1. In a web browser, using a work or school account that has been granted admin permissions, sign in to Office 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Remove encryption from incoming mail.
6. In **Apply this rule if** select the conditions where encryption should be removed from messages, such as **The recipient is located** > **Inside the organization**.
7. In **Do the following**, select **Modify the message security** > **Remove the previous version of OME**.
8. Select **Save**.

Use Exchange Online PowerShell to create a rule to remove encryption from email replies encrypted without the new OME capabilities

1. Connect to Exchange Online PowerShell. For more information, see Connect to Exchange Online PowerShell.
2. Create a rule by using the **New-TransportRule** cmdlet and set the *RemoveOME* parameter to `$true`.

   This example removes the encryption from all mail sent to recipients in the organization.

   ```
   New-TransportRule -Name "Remove encryption from incoming mail" -SentToScope "InOrganization" -
   RemoveOME $true
   ```

   Where,

   - The unique name of the new rule is "Remove encryption from incoming mail".
   - The *SentToScope* parameter specifies the location of the message recipients. In this example, the value `InOrganization` value is used, which indicates one of the following:
     - The recipient is a mailbox, mail user, group, or mail-enabled public folder in your organization.
     - The recipient's email address is in an accepted domain that's configured as an authoritative domain or an internal relay domain in your organization, *and* the message was sent or received over an authenticated connection.

For detailed syntax and parameter information, see New-TransportRule.

Sending, viewing, and replying to messages encrypted without the new capabilities

With Office 365 Message Encryption, email messages are encrypted automatically, based on administrator-defined rules. An email that bears an encrypted message arrives in the recipient's Inbox with an attached HTML file.

Recipients follow instructions in the message to open the attachment and authenticate by using a Microsoft account or a work or school associated with Office 365. If recipients don't have either account, they're directed to create a Microsoft account that will let them sign in to view the encrypted message. Alternatively, recipients can

choose to get a one-time pass code to view the message. After signing in or using a one-time pass code, recipients can view the decrypted message and send an encrypted reply.

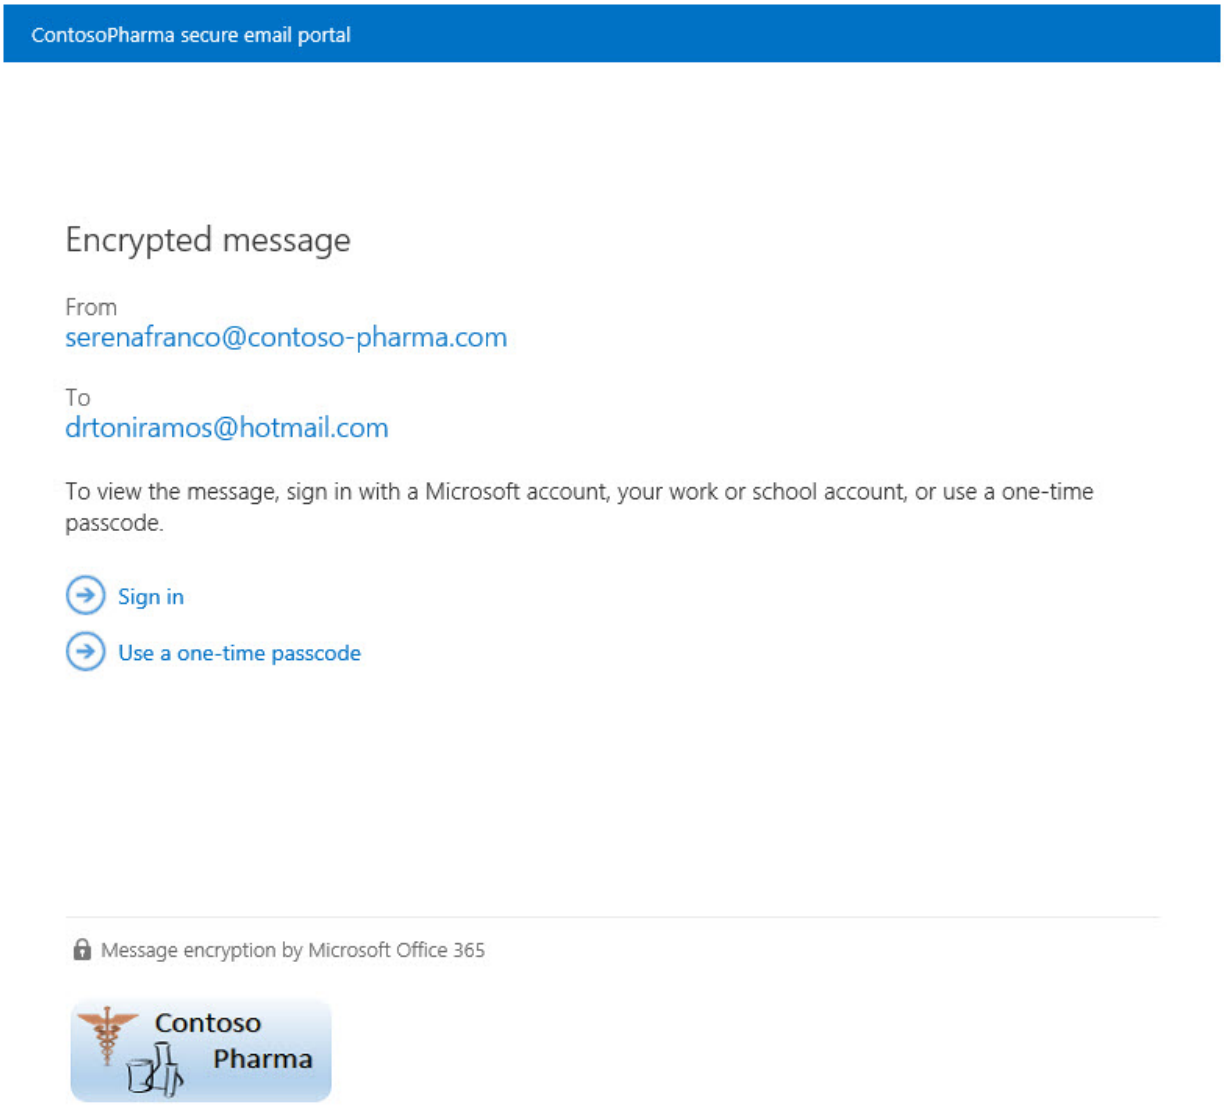
Customize encrypted messages with Office 365 Message Encryption

As an Exchange Online and Exchange Online Protection administrator, you can customize your encrypted messages. For example, you can add your company's brand and logo, specify an introduction, and add disclaimer text in encrypted messages and in the portal where recipients view your encrypted messages. Using Windows PowerShell cmdlets, you can customize the following aspects of the viewing experience for recipients of encrypted email messages:

- Introductory text of the email that contains the encrypted message
- Disclaimer text of the email that contains the encrypted message
- Portal text that will appear in the message viewing portal
- Logo that will appear in the email message and viewing portal

You can also revert back to the default look and feel at any time.

The following example shows a custom logo for ContosoPharma in the email attachment:



To customize encryption email messages and the encryption portal with your organization's brand

1. Connect to Exchange Online using Remote PowerShell, as described in Connect to Exchange Online Using

Remote PowerShell.

2. Use the Set-OMEConfiguration cmdlet as described here: Set-OMEConfiguration or use the following table for guidance.

Encryption customization options

TO CUSTOMIZE THIS FEATURE OF THE ENCRYPTION EXPERIENCE	USE THESE WINDOWS POWERSHELL COMMANDS

Default text that accompanies encrypted email messages The default text appears above the instructions for viewing encrypted messages	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -EmailText " <string of up to 1024 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -EmailText "Encrypted message from ContosoPharma secure messaging system"`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> DisclaimerText " <your disclaimer statement, string of up to 1024 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -DisclaimerText "This message is confidential for the use of the addressee only"`

Text that appears at the top of the encrypted mail viewing portal	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -PortalText "<text for your portal, string of up to 128 characters>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -PortalText "ContosoPharma secure email portal"`

Logo	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -Image <Byte[]>`
	Example:
	`Set-OMEConfiguration -Identity "OME configuration" -Image (Get-Content "C:\Temp\contosologo.png" -Encoding byte)`
	Supported file formats: .png, .jpg, .bmp, or .tiff
	Optimal size of logo file: less than 40 KB
	Optimal size of logo image: 170x70 pixels

To remove brand customizations from encryption email messages and the encryption portal

1. Connect to Exchange Online using Remote PowerShell, as described in Connect to Exchange Online Using Remote PowerShell.

2. Use the Set-OMEConfiguration cmdlet as described here: Set-OMEConfiguration. To remove your organization's branded customizations from the DisclaimerText, EmailText, and PortalText values, set the value to an empty string, `""`. For all image values, such as Logo, set the value to `"$null"`.

Encryption customization options

TO REVERT THIS FEATURE OF THE ENCRYPTION EXPERIENCE BACK TO THE DEFAULT TEXT AND IMAGE	USE THESE WINDOWS POWERSHELL COMMANDS

TO REVERT THIS FEATURE OF THE ENCRYPTION EXPERIENCE BACK TO THE DEFAULT TEXT AND IMAGE	USE THESE WINDOWS POWERSHELL COMMANDS

Default text that accompanies encrypted email messages The default text appears above the instructions for viewing encrypted messages	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -EmailText "<empty string>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -EmailText ""`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> DisclaimerText "<empty string>"`
	Example:
	`Set-OMEConfiguration -Identity "OME Configuration" -DisclaimerText ""`

Text that appears at the top of the encrypted mail viewing portal	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -PortalText "<empty string>"`
	Example reverting back to default:
	`Set-OMEConfiguration -Identity "OME Configuration" -PortalText ""`

Logo	`Set-OMEConfiguration -Identity <OMEConfigurationIdParameter> -Image <"$null">`
	Example reverting back to default:
	`Set-OMEConfiguration -Identity "OME configuration" -Image $null`

Service information for legacy Office 365 Message Encryption prior to the release of the new OME capabilities

The following table provides technical details for the Office 365 Message Encryption service prior to the release of the new OME capabilities.

SERVICE DETAILS	DESCRIPTION
Client device requirements	Encrypted messages can be viewed on any client device, as long as the HTML attachment can be opened in a modern browser that supports Form Post.
Encryption algorithm and Federal Information Processing Standards (FIPS) compliance	Office 365 Message Encryption uses the same encryption keys as Windows Azure Information Rights Management (IRM) and supports Cryptographic Mode 2 (2K key for RSA and 256 bits key for SHA-1 systems). For more information about the underlying IRM cryptographic modes, see AD RMS Cryptographic Modes.
Supported message types	Office 365 Message Encryption is only supported for items that have a message class ID of **IPM.Note**. For more information, see Item types and message classes.
Message size limits	Office 365 Message Encryption can encrypt messages of up to 25 megabytes. For more details about message size limits, see Exchange Online Limits.
Exchange Online email retention policies	Exchange Online doesn't store the encrypted messages.

SERVICE DETAILS	DESCRIPTION
Language support for Office 365 Message Encryption	Office 365 Message encryption supports Microsoft 365 languages, as follows: Incoming email messages and attached HTML files are localized based on the sender's language settings. The viewing portal is localized based on the recipient's browser settings. The body (content) of the encrypted message isn't localized.
Privacy information for OME Portal and OME Viewer App	The Office 365 Messaging Encryption Portal privacy statement provides detailed information about what Microsoft does and doesn't do with your private information.

Frequently Asked Questions about legacy OME

Got questions about Office 365 Message Encryption? Here are some answers. If you can't find what you need, check the Microsoft Tech Community forums for Office 365.

Q. My users send encrypted email messages to recipients outside our organization. Is there anything that external recipients have to do in order to read and reply to email messages that are encrypted with Office 365 Message Encryption?

Recipients outside your organization who receive Microsoft 365 encrypted messages can view them in one of two ways:

- By signing in with a Microsoft account or a work or school account associated with Office 365.
- By using a one-time pass code.

Q. Are Microsoft 365 encrypted messages stored in the cloud or on Microsoft servers?

No, the encrypted messages are kept on the recipient's email system, and when the recipient opens the message, it is temporarily posted for viewing on Microsoft servers. The messages are not stored there.

Q. Can I customize encrypted email messages with my brand?

Yes. You can use Windows PowerShell cmdlets to customize the default text that appears at the top of encrypted email messages, the disclaimer text, and the logo that you want to use for the email message and the encryption portal. This feature is now available in OMEv2. For details, see Add branding to encrypted messages.

Q. Does the service require a license for every user in my organization?

A license is required for every user in the organization who sends encrypted email.

Q. Do external recipients require subscriptions?

No, external recipients do not require a subscription to read or reply to encrypted messages.

Q. How is Office 365 Message Encryption different from Rights Management Services (RMS)?

RMS provides Information Rights Protection capabilities for an organization's internal emails by providing built-in templates, such as: Do not forward and Company Confidential. Office 365 Message Encryption supports email message encryption for messages that are sent to external recipients as well as internal recipients.

Q. How is Office 365 Message Encryption different from S/MIME?

S/MIME is essentially a client-side encryption technology, and requires complicated certificate management and publishing infrastructure. Office 365 Message Encryption uses mail flow rules (also known as transport rules) and does not depend on certificate publishing.

Q. Can I read the encrypted messages over mobile devices?

Yes, you can view messages on Android and iOS by downloading the OME Viewer apps from the Google Play store and the Apple App store. Open the HTML attachment in the OME Viewer app and then follow the instructions to open your encrypted message. For other mobile devices, you can open the HTML attachment as long as your mail client supports Form Post.

Q. Are replies and forwarded messages encrypted?

Yes. Responses continue to be encrypted throughout the duration of the thread.

Q. Does Office 365 Message Encryption provide localization?

Incoming email and HTML content is localized based on sender email settings. The viewing portal is localized based on recipient's browser settings. However, the actual body (content) of encrypted message isn't localized.

Q. What encryption method is used for Office 365 Message Encryption?

Office 365 Message Encryption uses Rights Management Services (RMS) as its encryption infrastructure. The encryption method used depends on where you obtain the RMS keys used to encrypt and decrypt messages.

- If you use Microsoft Azure RMS to obtain the keys, Cryptographic Mode 2 is used. Cryptographic Mode 2 is an updated and enhanced AD RMS cryptographic implementation. It supports RSA 2048 for signature and encryption, and supports SHA-256 for signature.
- If you use Active Directory (AD) RMS to obtain the keys, either Cryptographic Mode 1 or Cryptographic Mode 2 is used. The method used depends on your on-premises AD RMS deployment. Cryptographic Mode 1 is the original AD RMS cryptographic implementation. It supports RSA 1024 for signature and encryption, and supports SHA-1 for signature. This mode continues to be supported by all current versions of RMS.

For more information, see AD RMS Cryptographic Modes.

Q. Why do some encrypted messages say they come from Office365@messaging.microsoft.com?

When an encrypted reply is sent from the encryption portal or through the OME Viewer app, the sending email address is set to Office365@messaging.microsoft.com because the encrypted message is sent through a Microsoft endpoint. This helps to prevent encrypted messages from being marked as spam. The displayed name on the email and the address within the encryption portal aren't changed because of this labeling. Also, this labeling only applies to messages sent through the portal, not through any other email client.

Q. I am an Exchange Hosted Encryption (EHE) subscriber. Where can I learn more about the upgrade to Office 365 Message Encryption?

All EHE customers have been upgraded to Office 365 Message Encryption. For more information, visit the Exchange Hosted Encryption Upgrade Center.

Q. Do I need to open any URLs, IP addresses, or ports in my organization's firewall to support Office 365 Message Encryption?

Yes. You have to add URLs for Exchange Online to the allow list for your organization to enable authentication for messages encrypted by Office 365 Message Encryption. For a list of Exchange Online URLs, see Microsoft 365 URLs and IP address ranges.

Q. How many recipients can I send a Microsoft 365 encrypted message to?

The recipient limit is 500 recipients per message, or, when combined after distribution list expansion, 11,980 characters in the message's **To** field, whichever comes first.

Q. Is it possible to revoke a message sent to a particular recipient?

No. You can't revoke a message to a particular person after it's sent.

Q. Can I view a report of encrypted messages that have been received and read?

There isn't a report that shows if an encrypted message has been viewed, but there are Microsoft 365 reports available that you can leverage to determine the number of messages that matched a specific mail flow rule (also known as a transport rule), for instance.

Q. What does Microsoft do with the information I provide through the OME Portal and the OME Viewer App?

The Office 365 Messaging Encryption Portal privacy statement provides detailed information about what Microsoft does and doesn't do with your private information.

Q. What do I do if I don’t receive the one-time pass code after I requested it?

First, check the junk or spam folder in your email client. DKIM and DMARC settings for your organization may cause these emails to end up filtered as spam.

Next, check quarantine in the Security & Compliance Center. Often, messages containing a one-time pass code, especially the first ones your organization receives, end up in quarantine.

Set up Azure Rights Management for the previous version of Message Encryption

5/8/2020 • 5 minutes to read • Edit Online

This topic describes the steps you need to follow in order to activate and then set up Azure Rights Management (RMS), part of Azure Information Protection, for use with the previous version of Office 365 Message Encryption (OME).

This article only applies to the previous version of OME

If you haven't yet moved your organization to the new OME capabilities, but you have already deployed OME, then the information in this article applies to your organization. Microsoft recommends that you make a plan to move to the new OME capabilities as soon as it is reasonable for your organization. For instructions, see Set up new Office 365 Message Encryption capabilities. If you want to find out more about how the new capabilities work first, see Office 365 Message Encryption. The rest of this article refers to OME behavior before the release of the new OME capabilities.

Prerequisites for using the previous version of Office 365 Message Encryption

Office 365 Message Encryption (OME), including IRM, depends on Azure Rights Management (Azure RMS). Azure RMS is the protection technology used by Azure Information Protection. To use OME, your organization must include an Exchange Online or Exchange Online Protection subscription that, in turn, includes an Azure Rights Management subscription.

- If you're not sure of what your subscription includes, see the Exchange Online service descriptions for Message Policy, Recovery, and Compliance.
- If you have Azure Rights Management but it's not set up for Exchange Online or Exchange Online Protection, this article explains how to activate Azure Rights Management and then the describes the best way to set up OME to work with Azure Rights Management.
- If you've already set up OME to work with Azure Rights Management for Exchange Online or Exchange Online Protection, depending on how you set it up, you may be ready to start using OME and its new capabilities right away. This article explains how to determine if you've set OME up correctly, what to do if you need to change your setup, and what happens if you choose not to change your setup. For example, in order to use the new capabilities, you must use Azure RMS with OME. You can't use the new capabilities with an on-premises Active Directory RMS.

Activate Azure Rights Management for the previous version of OME in Office 365

You need to activate Azure Rights Management so that the users in your organization can apply information protection to messages that they send, and open messages and files that have been protected by the Azure Rights Management service. For instructions, see Activating Azure Rights Management. Once you've completed the activation, return here and continue with the tasks in this article.

Set up the previous version of OME to use Azure RMS by importing

trusted publishing domains (TPDs)

A TPD is an XML file that contains information about your organization's rights management settings. For example, the TPD contains information about the server licensor certificate (SLC) used for signing and encrypting certificates and licenses, the URLs used for licensing and publishing, and so on. You import the TPD into your organization by using Windows PowerShell.

> **IMPORTANT**
> Previously, you could choose to import TPDs from the Active Directory Rights Management service (AD RMS) into your organization. However, doing so will prevent you from using the new OME capabilities and is not recommended. If your organization is currently configured this way, Microsoft recommends that you create a plan to migrate from your on-premises Active Directory RMS to cloud-based Azure Information Protection. For more information, see Migrating from AD RMS to Azure Information Protection. You will not be able to use the new OME capabilities until you have completed the migration to Azure Information Protection.

To import TPDs from Azure RMS

1. Connect to Exchange Online Using Remote PowerShell.
2. Choose the key-sharing URL that corresponds to your organization's geographic location:

LOCATION	KEY SHARING LOCATION URL
North America	https://sp-rms.na.aadrm.com/TenantManagement/ServicePartner.svc
European Union	https://sp-rms.eu.aadrm.com/TenantManagement/ServicePartner.svc
Asia	https://sp-rms.ap.aadrm.com/TenantManagement/ServicePartner.svc
South America	https://sp-rms.sa.aadrm.com/TenantManagement/ServicePartner.svc
Office 365 for Government (Government Community Cloud) This RMS key-sharing location is reserved for customers who have purchased Office 365 for Government SKUs.	https://sp-rms.govus.aadrm.com/TenantManagement/ServicePartner.svc

3. Configure the key-sharing location by running the Set-IRMConfiguration cmdlet as follows:

```
Set-IRMConfiguration -RMSOnlineKeySharingLocation "<RMSKeySharingURL >"
```

   For example, to configure the key sharing location if your organization is located in North America:

```
Set-IRMConfiguration -RMSOnlineKeySharingLocation "https://sp-rms.na.aadrm.com/TenantManagement/ServicePartner.svc"
```

4. Run the Import-RMSTrustedPublishingDomain cmdlet with the -RMSOnline switch to import the TPD from Azure Rights Management:

```
Import-RMSTrustedPublishingDomain -RMSOnline -Name "<TPDName> "
```

Where *TPDName* is the name you want to use for the TPD. For example, "Contoso North American TPD".

5. To verify that you successfully configured your organization to use the Azure Rights Management service, run the Test-IRMConfiguration cmdlet with the -RMSOnline switch as follows:

   ```
   Test-IRMConfiguration -RMSOnline
   ```

   Among other things, this cmdlet checks connectivity with the Azure Rights Management service, downloads the TPD, and checks its validity.

6. Run the Set-IRMConfiguration cmdlet as follows to disable Azure Rights Management templates from being available in Outlook on the web and Outlook:

   ```
   Set-IRMConfiguration -ClientAccessServerEnabled $false
   ```

7. Run the Set-IRMConfiguration cmdlet as follows to enable Azure Rights Management for your cloud-based email organization and configure it to use Azure Rights Management for Office 365 Message Encryption:

   ```
   Set-IRMConfiguration -InternalLicensingEnabled $true
   ```

8. To verify that you have successfully imported the TPD and enabled Azure Rights Management, use the Test-IRMConfiguration cmdlet to test Azure Rights Management functionality. For details, see "Example 1" in Test-IRMConfiguration.

I have the previous version of OME set up with Active Directory Rights Management not Azure Information Protection, what do I do?

You can continue to use your existing Office 365 Message Encryption mail flow rules with Active Directory Rights Management, but you can't configure or use the new OME capabilities. Instead, you need to migrate to Azure Information Protection. For information about migration and what this means for your organization, see Migrating from AD RMS to Azure Information Protection.

Next steps

Once you've completed Azure Rights Management setup, if you want to enable the new OME capabilities, see Set up new Office 365 Message Encryption capabilities built on top of Azure Information Protection.

After you've set up your organization to use the new OME capabilities, you're ready to Define mail flow rules to protect email messages with new OME capabilities.

What is Azure Rights Management?

Set up Information Rights Management (IRM) in SharePoint admin center

11/2/2020 • 3 minutes to read • Edit Online

Within SharePoint Online, IRM protection is applied to files at the list and library level. Before your organization can use IRM protection, you must first set up Rights Management. IRM relies on the Azure Rights Management service from Azure Information Protection to encrypt and assign usage restrictions. Some Microsoft 365 plans include Azure Rights Management, but not all. To learn more, read How Office applications and services support Azure Rights Management.

Turn on IRM service using SharePoint admin center

Before your organization can IRM-protect SharePoint lists and libraries, you must first activate the Rights Management service for your organization. To learn how see Activating Azure Rights Management. You must use a work or school account that has global administrator privileges to enable the Rights Management service. Otherwise, you won't be able to use IRM features with SharePoint Online.

After activating the Rights Management service, sign in to the SharePoint admin center to turn on IRM.

1. Sign in as a global admin or SharePoint admin.
2. Select the app launcher icon in the upper-left and choose **Admin** to open the Microsoft 365 admin center. (If you don't see the Admin tile, you don't have administrator permissions in your organization.)
3. In the left pane, choose **Admin centers** > **SharePoint**.
4. In the left pane, choose **settings**, and then choose **classic settings page**.
5. In the **Information Rights Management (IRM)** section, choose **Use the IRM service specified in your configuration**, and then choose **Refresh IRM Settings**. After you refresh IRM settings, people in your organization can begin using IRM in their SharePoint lists and document libraries. However, the options to do so may take up to an hour to appear in Library Settings and List Settings.

IRM-enable SharePoint document libraries and lists

After refreshing IRM settings, site owners can IRM-protect their SharePoint lists and document libraries. For more information, see Apply Information Rights Management to a list or library.

When site owners enable IRM for a list or library, they can protect any supported file types in that list or library. When IRM is enabled for a library, rights management applies to all of the files in that library. When you enable IRM for a list, rights management applies only to files that are attached to list items, not the actual list items.

When people download files in an IRM-enabled list or library, the files are encrypted so that only authorized people can view them. Each rights-managed file also contains an issuance license that imposes restrictions on the people who view the file. Typical restrictions include making a file read-only, disabling the copying of text, preventing people from saving a local copy, and preventing people from printing the file. Client programs that can read IRM-supported file types use the issuance license within the rights-managed file to enforce these restrictions. This is how a rights-managed file retains its protection even after it is downloaded. To enable IRM on a list or library, see Apply Information Rights Management to a list or library.

You cannot create or edit documents in an IRM-enabled library using Office in a browser. Instead, one person at a time can download and edit IRM-encrypted files. Use check-in and check-out to manage *co-authoring* , or

authoring across multiple users.

When you download a PDF file from an IRM-protected library, Microsoft 365 creates a protected PDF file. The file's extension won't change, but the file is protected. To view this file you'll need the Azure Information Protection viewer, the full Azure Information Protection client, or another application that supports viewing protected PDF files.

SharePoint Online supports encryption of the following file types:

- PDF
- The 97-2003 file formats for the following Microsoft Office programs: Word, Excel, and PowerPoint
- The Office Open XML formats for the following Microsoft Office programs: Word, Excel, and PowerPoint
- The XML Paper Specification (XPS) format

> **NOTE**
> IRM protection cannot be applied to protected documents (like digitally signed PDF files) as SharePoint needs to open the document on upload.

Next steps

Once you've enabled IRM for SharePoint Online, you can start applying rights management to lists and libraries. For information, see Apply Information Rights Management to a list or library.

The new OneDrive sync client for Windows now supports synchronizing IRM-protected SharePoint document libraries and OneDrive locations (as long as the IRM setting for the library isn't set to expire document access rights). For more information, or to get started deploying the new sync client, see Deploy the new OneDrive sync client for Windows.

Technical reference details about encryption

2/18/2021 • 4 minutes to read • Edit Online

Refer to this article to learn about certificates, technologies, and TLS cipher suites used for encryption in Office 365. This article also provides details about planned deprecations.

- If you're looking for overview information, see Encryption in Office 365.
- If you're looking for setup information, see Set up encryption in Office 365 Enterprise.
- For information about cipher suites supported by specific versions of Windows, see Cipher Suites in TLS/SSL (Schannel SSP).

Microsoft Office 365 certificate ownership and management

You don't need to purchase or maintain certificates for Office 365. Instead, Office 365 uses its own certificates.

Current encryption standards and planned deprecations

To provide best-in-class encryption, Office 365 regularly reviews supported encryption standards. Sometimes, old standards are deprecated as they become out of date and less secure. This article describes currently supported cipher suites and other standards and details about planned deprecations.

FIPS compliance for Office 365

All cipher suites supported by Office 365 use algorithms acceptable under FIPS 140-2. Office 365 inherits FIPS validations from Windows (through Schannel). For information about Schannel, see Cipher Suites in TLS/SSL (Schannel SSP).

Versions of TLS supported by Office 365

TLS, and SSL that came before TLS, are cryptographic protocols that secure communication over a network by using security certificates to encrypt a connection between computers. Office 365 supports TLS version 1.2 (TLS 1.2).

TLS version 1.3 (TLS 1.3) is currently not supported.

Support for TLS 1.0 and 1.1 deprecation

Office 365 stopped supporting TLS 1.0 and 1.1 on October 31, 2018. We have completed disabling TLS 1.0 and 1.1 in GCC High and DoD environments. We began disabling TLS 1.0 and 1.1 for Worldwide and GCC environments beginning on October 15, 2020 and will continue with roll-out over the next weeks and months.

To maintain a secure connection to Office 365 and Microsoft 365 services, all client-server and browser-server combinations use TLS 1.2 and modern cipher suites. You might have to update certain client-server and browser-server combinations. For information about how this change impacts you, see Preparing for the mandatory use of TLS 1.2 in Office 365.

Deprecating support for 3DES

Since October 31, 2018, Office 365 no longer supports the use of 3DES cipher suites for communication to Office 365. More specifically, Office 365 no longer supports the TLS_RSA_WITH_3DES_EDE_CBC_SHA cipher suite. Since February 28, 2019, this cipher suite has been disabled in Office 365. Clients and servers that

communicate with Office 365 must support one or more of the supported ciphers. For a list of supported ciphers, see TLS cipher suites supported by Office 365.

Deprecating SHA-1 certificate support in Office 365

Since June 2016, Office 365 no longer accepts an SHA-1 certificate for outbound or inbound connections. Use SHA-2 (Secure Hash Algorithm 2) or a stronger hashing algorithm in the certificate chain.

TLS cipher suites supported by Office 365

TLS uses *cipher suites*, collections of encryption algorithms, to establish secure connections. Office 365 supports the cipher suites listed in the following table. The table lists the cipher suites in order of strength, with the strongest cipher suite listed first.

Office 365 responds to a connection request by first attempting to connect using the most secure cipher suite. If the connection doesn't work, Office 365 tries the second most secure cipher suite in the list, and so on. The service continues down the list until the connection is accepted. Likewise, when Office 365 requests a connection, the receiving service chooses whether TLS will be used and which cipher suite to use.

> **IMPORTANT**
> Be aware that TLS versions deprecate, and that deprecated versions *should not be used* where newer versions are available. TLS 1.3 is currently not supported. If your legacy services do not require TLS 1.0 or 1.1 you should disable them.

CIPHER SUITE	KEY EXCHANGE ALGORITHM/STRENGTH	FORWARD SECRECY	CIPHER/STRENGTH	AUTHENTICATION ALGORITHM
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	ECDH/192	Yes	AES/256	RSA/112
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	ECDH/128	Yes	AES/128	RSA/112
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	ECDH/192	Yes	AES/256	RSA/112
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	ECDH/128	Yes	AES/128	RSA/112
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	ECDH/192	Yes	AES/256	RSA/112
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	ECDH/128	Yes	AES/128	RSA/112
TLS_RSA_WITH_AES_256_GCM_SHA384	RSA/112	No	AES/256	RSA/112

CIPHER SUITE	KEY EXCHANGE ALGORITHM/STRENGTH	FORWARD SECRECY	CIPHER/STRENGTH	AUTHENTICATION ALGORITHM
TLS_RSA_WITH_AES_128_GCM_SHA256	RSA/112	No	AES/256	RSA/112

These cipher suites supported TLS 1.0 and 1.1 protocols until their deprecation date. For GCC High and DoD environments that deprecation date was January 15, 2020, and for Worldwide and GCC environments that date was October 15, 2020.

PROTOCOLS	CIPHER SUITE NAME	KEY EXCHANGE ALGORITHM/STRENGTH	FORWARD SECRECY SUPPORT	AUTHENTICATION ALGORITHM/STRENGTH	CIPHER/STRENGTH
TLS 1.0, 1.1, 1.2	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	ECDH/192	Yes	RSA/112	AES/256
TLS 1.0, 1.1, 1.2	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	ECDH/128	Yes	RSA/112	AES/128
TLS 1.0, 1.1, 1.2	TLS_RSA_WITH_AES_256_CBC_SHA	RSA/112	No	RSA/112	AES/256
TLS 1.0, 1.1, 1.2	TLS_RSA_WITH_AES_128_CBC_SHA	RSA/112	No	RSA/112	AES/128
TLS 1.0, 1.1, 1.2	TLS_RSA_WITH_AES_256_CBC_SHA256	RSA/112	No	RSA/112	AES/256
TLS 1.0, 1.1, 1.2	TLS_RSA_WITH_AES_128_CBC_SHA256	RSA/112	No	RSA/112	AES/256

Disabling TLS 1.0 and 1.1 for Microsoft 365

2/18/2021 • 3 minutes to read • Edit Online

> **IMPORTANT**
>
> We temporarily halted disablement of TLS 1.0 and 1.1 for commercial customers due to COVID-19. As supply chains have adjusted and certain countries open back up, we restarted the TLS 1.2 enforcement rollout on October 15, 2020. Rollout will continue over the following weeks and months.

As of October 31, 2018, the Transport Layer Security (TLS) 1.0 and 1.1 protocols are deprecated for the Microsoft 365 service. The effect for end-users is minimal. This change has been publicized for over two years, with the first public announcement made in December 2017. This article is only intended to cover the Office 365 local client in relation to the Office 365 service but can also apply to on-premises TLS issues with Office and Office Online Server/Office Web Apps.

For SharePoint and OneDrive, you'll need to update and configure .NET to support TLS 1.2. For information, see How to enable TLS 1.2 on clients.

Office 365 and TLS overview

The Office client relies on the Windows web service (WINHTTP) to send and receive traffic over TLS protocols. The Office client can use TLS 1.2 if the web service of the local computer can use TLS 1.2. All Office clients can use TLS protocols, as TLS and SSL protocols are part of the operating system and not specific to the Office client.

On Windows 8 and later versions

By default, the TLS 1.2 and 1.1 protocols are available if no network devices are configured to reject TLS 1.2 traffic.

On Windows 7

TLS 1.1 and 1.2 protocols are not available without the KB 3140245 update. The update addresses this issue and adds the following registry sub key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Internet Settings\WinHttp
```

> **NOTE**
>
> Windows 7 users who do not have this update are affected as of October 31, 2018. KB 3140245 has details about how to change WINHTTP settings to enable TLS protocols.

More information

The value of the **DefaultSecureProtocols** registry key that the KB article describes determines which network protocols can be used:

DEFAULTSECUREPROTOCOLS VALUE	PROTOCOL ENABLED
0x00000008	Enable SSL 2.0 by default
0x00000020	Enable SSL 3.0 by default

DEFAULTSECUREPROTOCOLS VALUE	PROTOCOL ENABLED
0x00000080	Enable TLS 1.0 by default
0x00000200	Enable TLS 1.1 by default
0x00000800	Enable TLS 1.2 by default

Office clients and TLS registry keys

You can refer to KB 4057306 Preparing for the mandatory use of TLS 1.2 in Office 365. This is a general article for IT administrators, and it's official documentation about the TLS 1.2 change.

The following table shows the appropriate registry key values in Office 365 clients after October 31, 2018.

ENABLED PROTOCOLS FOR OFFICE 365 SERVICE AFTER OCTOBER 31, 2018	HEXADECIMAL VALUE
TLS 1.0 + 1.1 + 1.2	0x00000A80
TLS 1.1 + 1.2	0x00000A00
TLS 1.0 + 1.2	0x00000880
TLS 1.2	0x00000800

IMPORTANT

Don't use the SSL 2.0 and 3.0 protocols, which can also be set by using the **DefaultSecureProtocols** key. SSL 2.0 and 3.0 are considered outdated and insecure protocols. The best practice is to end the use of SSL 2.0 and SSL 3.0, although the decision to do this ultimately depends on what best meets your product needs. For more information about SSL 3.0 vulnerabilities, refer to KB 3009008.

You can use the default Windows Calculator in Programmer mode to set up the same reference registry key values. For more information, see KB 3140245 Update to enable TLS 1.1 and TLS 1.2 as a default secure protocols in WinHTTP in Windows.

Regardless if the Windows 7 update (KB 3140245) is installed or not, the DefaultSecureProtocols registry sub key isn't present and must be added manually or through a group policy object (GPO). That is, unless you have to customize what secure protocols are enabled or restricted, this key is not required. You only need the Windows 7 SP1 (KB 3140245) update.

Update and configure the .NET Framework to support TLS 1.2

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients.

More information

For more information, see Preparing for the mandatory use of TLS 1.2 in Office 365.

Disabling TLS 1.0 and 1.1 in Office 365 GCC High and DoD

2/18/2021 • 2 minutes to read • Edit Online

Summary

In order to comply with the latest compliance standards for the Federal Risk and Authorization Management Program (FedRAMP), we are disabling Transport Layer Security (TLS) versions 1.1 and 1.0 in Microsoft 365 for GCC High and DoD environments. This change was previously announced through Microsoft Support in Preparing for the mandatory use of TLS 1.2 in Office 365.

The security of your data is important, and we are committed to transparency about changes that could affect your use of the service.

Although the Microsoft TLS 1.0 implementation has no known security vulnerabilities, we remain committed to the FedRAMP compliance standards. Therefore, we disabled TLS 1.1 and 1.0 in Office 365 in GCC High and DoD environments on January 15, 2020. For information about how to remove TLS 1.1 and 1.0 dependencies, see the following white paper:

Solving the TLS 1.0 problem

More information

Starting on January 15, 2020, Office 365 in the GCC High and DoD environments will deprecate TLS 1.1 and 1.0.

By January 15, 2020, all combinations of client servers and browser servers should use TLS version 1.2 (or a later version) to make sure that all connections can be made without issues to Office 365 services. This may require updates to certain combinations of client servers and browser servers.

If you do not update to TLS version 1.2 (or a later version) by January 15, 2020, you will experience issues when you try to connect to Office 365. Additionally, you will be required to update to TLS 1.2 (or a later version) as part of the resolution.

You must update your client computers to make sure that you maintain uninterrupted access to Office 365 GCC High and DoD.

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients. For more information, see Preparing for the mandatory use of TLS 1.2 in Office 365.

We know that the following client applications cannot use TLS 1.2:

- Android 4.3 and earlier versions
- Firefox version 5.0 and earlier versions
- Internet Explorer 8–10 on Windows 7 and earlier versions
- Internet Explorer 10 on Windows Phone 8.0
- Safari 6.0.4/OS X 10.8.4 and earlier versions

Although current analysis of connections to Microsoft Online services shows that most services and endpoints see very little TLS 1.1 and 1.0 usage, we're providing notice of this change so that you can update any affected clients or servers as necessary before support for TLS 1.1 and 1.0 ends. If you are using any on-premises infrastructure for hybrid scenarios or Active Directory Federation Services (AD FS), make sure that the

infrastructure can support both inbound and outbound connections that use TLS 1.2 (or a later version).

In addition to the outages that you might experience if you use the listed clients that cannot use TLS 1.2, removing TLS 1.1 and 1.0 will prevent you from being able to use the following Microsoft product:

- Lync phone

References

The following support article describes guidance and references to help make sure that your clients are using TLS 1.2:

Preparing for the mandatory use of TLS 1.2 in Office 365

Preparing for TLS 1.2 in Office 365 and Office 365 GCC

2/18/2021 • 3 minutes to read • Edit Online

Summary

To provide the best-in-class encryption to our customers, Microsoft plans to deprecate Transport Layer Security (TLS) versions 1.0 and 1.1 in Office 365 and Office 365 GCC. We understand that the security of your data is important, and we're committed to transparency about changes that may affect your use of the TLS service.

The Microsoft TLS 1.0 implementation has no known security vulnerabilities. But because of the potential for future protocol downgrade attacks and other TLS vulnerabilities, we are discontinuing support for TLS 1.0 and 1.1 in Microsoft Office 365 and Office 365 GCC.

For information about how to remove TLS 1.0 and 1.1 dependencies, see the following white paper: Solving the TLS 1.0 problem.

More information

We have already begun deprecation of TLS 1.0 and 1.1 as of January 2020. Any clients, devices, or services that connect to Office 365 through TLS 1.0 or 1.1 in our DoD or GCC High instances are unsupported. For our commercial customers of Office 365, deprecation of TLS 1.0 and 1.1 will begin October 15, 2020 and rollout will continue over the following weeks and months.

We recommend that all client-server and browser-server combinations use TLS 1.2 (or a later version) in order to maintain connection to Office 365 services. You might have to update certain client-server and browser-server combinations.

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients.

The following clients are known to be unable to use TLS 1.2. Update these clients to ensure uninterrupted access to the service.

- Android 4.3 and earlier versions
- Firefox version 5.0 and earlier versions
- Internet Explorer 8-10 on Windows 7 and earlier versions
- Internet Explorer 10 on Windows Phone 8
- Safari 6.0.4/OS X10.8.4 and earlier versions

TLS 1.2 for Microsoft Teams Rooms and Surface Hub

Microsoft Teams Rooms (previously known as Skype Room System V2 SRS V2) have supported TLS 1.2 since December 2018. We recommend that Rooms devices have Microsoft Teams Rooms app version 4.0.64.0 or later installed. For more information, see the Release notes. The changes are backward and forward compatible.

Surface Hub released TLS 1.2 support in May 2019.

TLS 1.2 support for Microsoft Teams Rooms and Surface Hub products also requires the following server-side code changes:

- Skype for Business Online server changes were made live in April 2019. Now, Skype for Business Online

supports connecting Microsoft Teams Rooms and Surface Hub devices by using TLS 1.2.

- Skype for Business Server customers must install a cumulative update (CU) to use TLS 1.2 for Teams Rooms Systems and Surface Hub.
  - For Skype for Business Server 2015, CU9 is already released in May 2019.
  - For Skype for Business Server 2019, CU1 was previously planned for April 2019 but is delayed to June 2019.

> **NOTE**
> Skype for Business on-premises customers should not disable TLS 1.0/1.1 before installing specific CUs for Skype for Business Server.

If you are using any on-premises infrastructure for hybrid scenarios or Active Directory Federation Services, make sure that the infrastructure can support both inbound and outbound connections that use TLS 1.2.

References

The following resources provide guidance to help make sure that your clients are using TLS 1.2 or a later version and to disable TLS 1.0 and 1.1.

- For Windows 7 clients that connect to Office 365, make sure that TLS 1.2 is the default secure protocol in WinHTTP in Windows. For more information see KB 3140245 - Update to enable TLS 1.1 and TLS 1.2 as a default secure protocols in WinHTTP in Windows.
- To start addressing weak TLS use by removing TLS 1.0 and 1.1 dependencies, see TLS 1.2 support at Microsoft.
- New IIS functionality makes it easier to find clients on Windows Server 2012 R2 and Windows Server 2016 that connect to the service by using weak security protocols.
- Get more information about how to solve the TLS 1.0 problem.

Overview of data loss prevention

2/18/2021 • 29 minutes to read • Edit Online

NOTE

Data loss prevention capabilities were recently added to Microsoft Teams chat and channel messages for users licensed for Office 365 Advanced Compliance, which is available as a standalone option and is included in Office 365 E5 and Microsoft 365 E5 Compliance. To learn more about licensing requirements, see Microsoft 365 Tenant-Level Services Licensing Guidance.

To comply with business standards and industry regulations, organizations must protect sensitive information and prevent its inadvertent disclosure. Sensitive information can include financial data or personally identifiable information (PII) such as credit card numbers, social security numbers, or health records. With a data loss prevention (DLP) policy in the Office 365 Security & Compliance Center, you can identify, monitor, and automatically protect sensitive information across Office 365.

With a DLP policy, you can:

- **Identify sensitive information across many locations, such as Exchange Online, SharePoint Online, OneDrive for Business, and Microsoft Teams.**

  For example, you can identify any document containing a credit card number that's stored in any OneDrive for Business site, or you can monitor just the OneDrive sites of specific people.

- **Prevent the accidental sharing of sensitive information.**

  For example, you can identify any document or email containing a health record that's shared with people outside your organization, and then automatically block access to that document or block the email from being sent.

- **Monitor and protect sensitive information in the desktop versions of Excel, PowerPoint, and Word.**

  Just like in Exchange Online, SharePoint Online, and OneDrive for Business, these Office desktop programs include the same capabilities to identify sensitive information and apply DLP policies. DLP provides continuous monitoring when people share content in these Office programs.

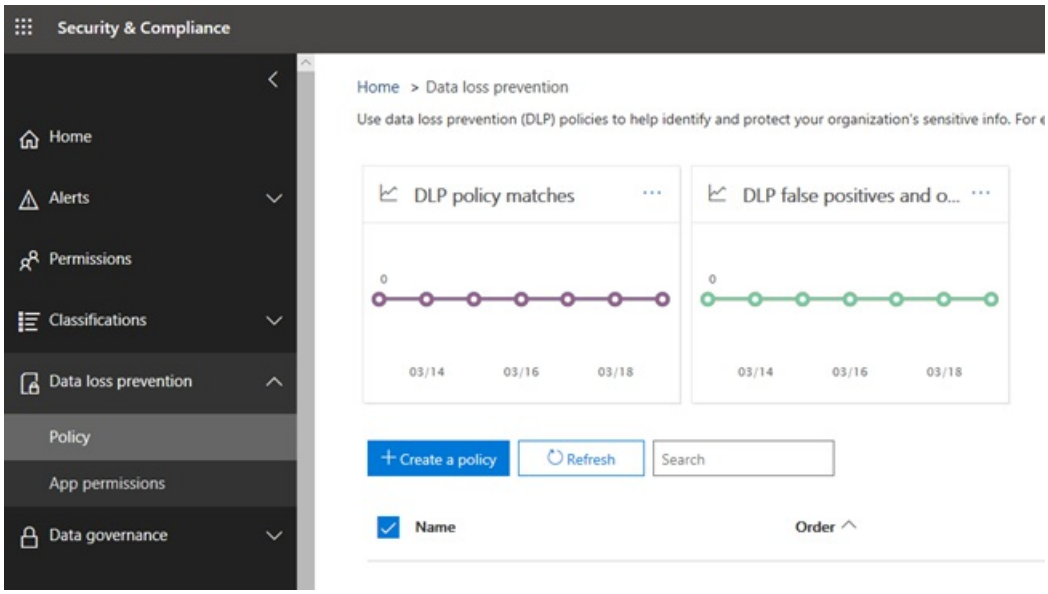
- **Help users learn how to stay compliant without interrupting their workflow.**

  You can educate your users about DLP policies and help them remain compliant without blocking their work. For example, if a user tries to share a document containing sensitive information, a DLP policy can both send them an email notification and show them a policy tip in the context of the document library that allows them to override the policy if they have a business justification. The same policy tips also appear in Outlook on the web, Outlook, Excel, PowerPoint, and Word.

- **View DLP alerts and reports showing content that matches your organization's DLP policies.**

  To view alerts and metadata related to your DLP policies you can use the DLP Alerts Management Dashboard. You can also view policy match reports to assess how your organization is complying with a DLP policy. If a DLP policy allows users to override a policy tip and report a false positive, you can also view what users have reported

You create and manage DLP policies on the Data loss prevention page in the Microsoft 365 Compliance center.



What a DLP policy contains

A DLP policy contains a few basic things:

- Where to protect the content: **locations** such as Exchange Online, SharePoint Online, and OneDrive for Business sites, as well as Microsoft Teams chat and channel messages.
- When and how to protect the content by enforcing **rules** comprised of:
  - **Conditions** the content must match before the rule is enforced. For example, a rule might be configured to look only for content containing Social Security numbers that's been shared with people outside your organization.
  - **Actions** that you want the rule to take automatically when content matching the conditions is found. For example, a rule might be configured to block access to a document and send both the user and compliance officer an email notification.

You can use a rule to meet a specific protection requirement, and then use a DLP policy to group together common protection requirements, such as all of the rules needed to comply with a specific regulation.

For example, you might have a DLP policy that helps you detect the presence of information subject to the Health Insurance Portability and Accountability Act (HIPAA). This DLP policy could help protect HIPAA data (the what) across all SharePoint Online sites and all OneDrive for Business sites (the where) by finding any document containing this sensitive information that's shared with people outside your organization (the conditions) and then blocking access to the document and sending a notification (the actions). These requirements are stored as individual rules and grouped together as a DLP policy to simplify management and reporting.

Locations

DLP policies are applied to sensitive items across Microsoft 365 locations and can be further scoped as detailed in this table.

LOCATION	INCLUDE/EXCLUDE BY
Exchange email	distribution groups
SharePoint sites	sites
OneDrive accounts	accounts
Teams chat and channel messages	accounts
Windows 10 devices	user or group
Microsoft Cloud App Security	instance

If you choose to include specific distribution groups in Exchange, the DLP policy will be scoped only to the members of that group. Similarly excluding a distribution group will exclude all the members of that distribution group from policy evaluation. You can choose to scope a policy to the members of distribution lists, dynamic distribution groups, and security groups. A DLP policy can contain no more than 50 such inclusions and exclusions.

If you choose to include or exclude specific SharePoint sites or OneDrive accounts, a DLP policy can contain no more than 100 such inclusions and exclusions. Although this limit exists, you can exceed this limit by applying either an org-wide policy or a policy that applies to entire locations.

Rules

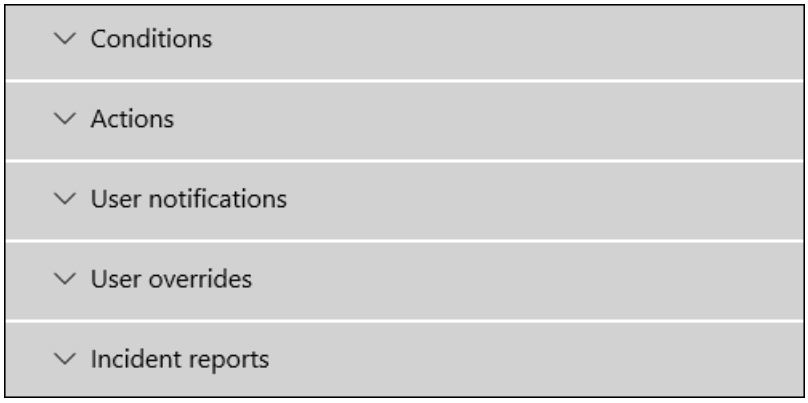
> **NOTE**
> The default behavior of a DLP policy, when there is no alert configured, is not to alert or trigger. This applies only to default information types. For custom information types, the system will alert even if there is no action defined in the policy.

Rules are what enforce your business requirements on your organization's content. A policy contains one or more rules, and each rule consists of conditions and actions. For each rule, when the conditions are met, the actions are taken automatically. Rules are executed sequentially, starting with the highest-priority rule in each

policy.

A rule also provides options to notify users (with policy tips and email notifications) and admins (with email incident reports) that content has matched the rule.

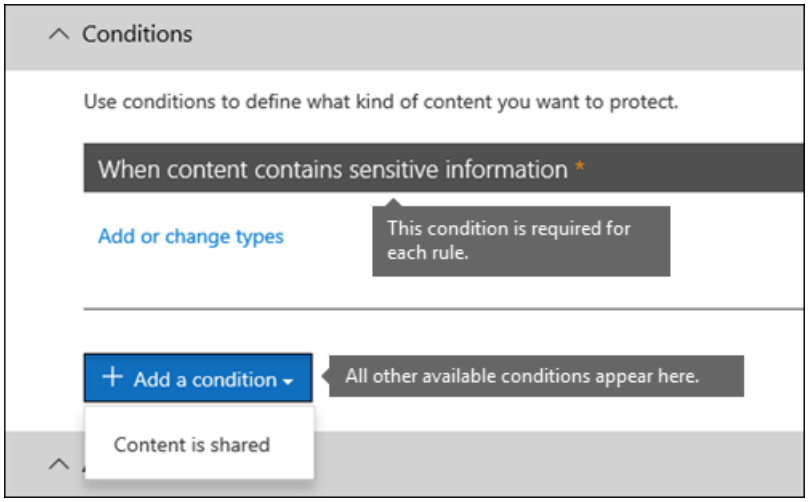
Here are the components of a rule, each explained below.



Conditions

Conditions are important because they determine what types of information you're looking for, and when to take an action. For example, you might choose to ignore content containing passport numbers unless the content contains more than 10 such numbers and is shared with people outside your organization.

Conditions focus on the **content**, such as what types of sensitive information you're looking for, and also on the **context**, such as who the document is shared with. You can use conditions to assign different actions to different risk levels. For example, sensitive content shared internally might be lower risk and require fewer actions than sensitive content shared with people outside the organization.



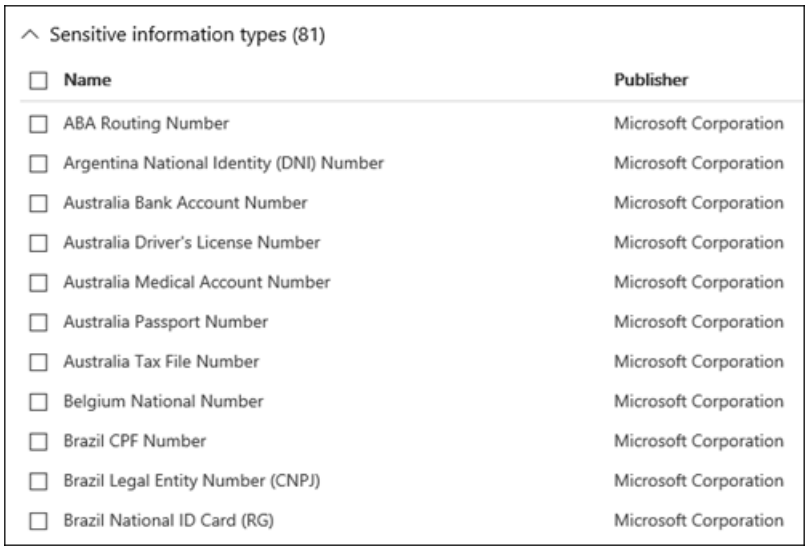
The conditions now available can determine if:

- Content contains a type of sensitive information.
- Content contains a label. For more information, see the below section Using a retention label as a condition in a DLP policy.
- Content is shared with people outside or inside your organization.

> **NOTE**
> Users who have non-guest accounts in a host organization's Active Directory or Azure Active Directory tenant are considered as people inside the organization.

Types of sensitive information

A DLP policy can help protect sensitive information, which is defined as a **sensitive information type**. Microsoft 365 includes definitions for many common sensitive information types across many different regions that are ready for you to use, such as a credit card number, bank account numbers, national ID numbers, and passport numbers.



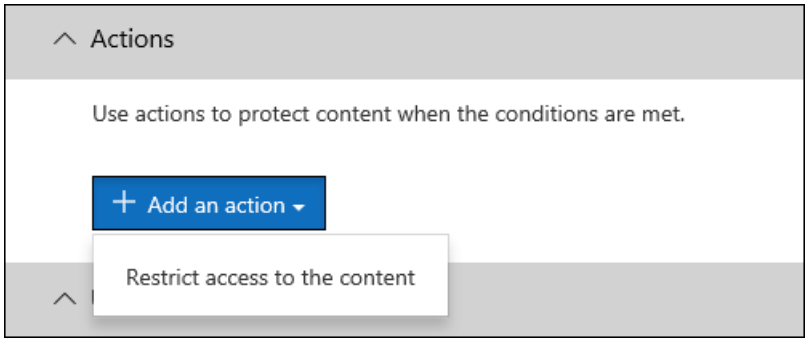
When a DLP policy looks for a sensitive information type such as a credit card number, it doesn't simply look for a 16-digit number. Each sensitive information type is defined and detected by using a combination of:

- Keywords.
- Internal functions to validate checksums or composition.
- Evaluation of regular expressions to find pattern matches.
- Other content examination.

This helps DLP detection achieve a high degree of accuracy while reducing the number of false positives that can interrupt peoples' work.

Actions

When content matches a condition in a rule, you can apply actions to automatically protect the content.



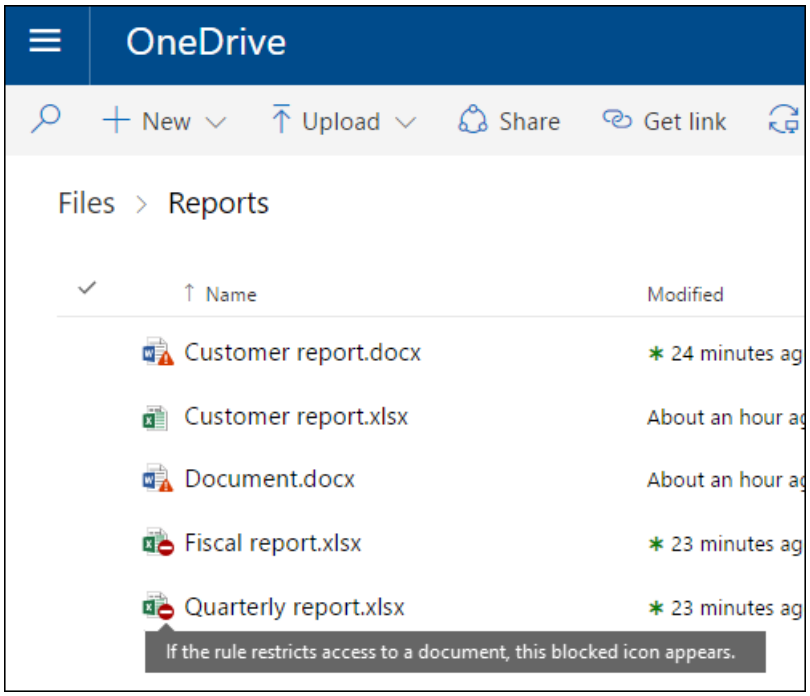
With the actions now available, you can:

- **Restrict access to the content** Depending on your need, you can restrict access to content in three ways:

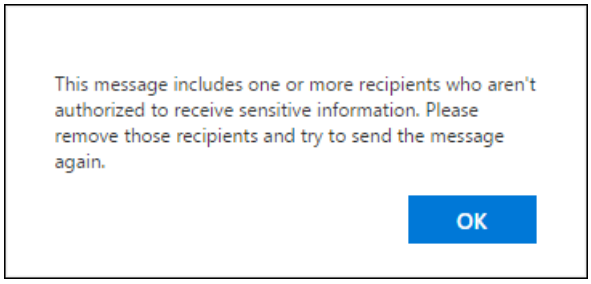
  1. Restrict access to content for everyone.
  2. Restrict access to content for people outside the organization.
  3. Restrict access to "Anyone with the link."

  For site content, this means that permissions for the document are restricted for everyone except the primary site collection administrator, document owner, and person who last modified the document. These people can remove the sensitive information from the document or take other remedial action.

When the document is in compliance, the original permissions are automatically restored. When access to a document is blocked, the document appears with a special policy tip icon in the library on the site.

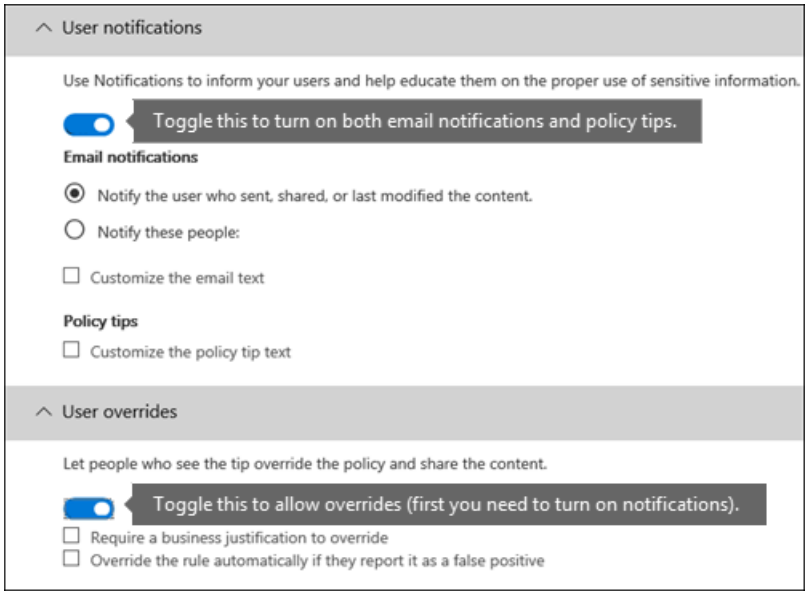


For email content, this action blocks the message from being sent. Depending on how the DLP rule is configured, the sender sees an NDR or (if the rule uses a notification) a policy tip and/or email notification.



User notifications and user overrides

You can use notifications and overrides to educate your users about DLP policies and help them remain compliant without blocking their work. For example, if a user tries to share a document containing sensitive information, a DLP policy can both send them an email notification and show them a policy tip in the context of the document library that allows them to override the policy if they have a business justification.



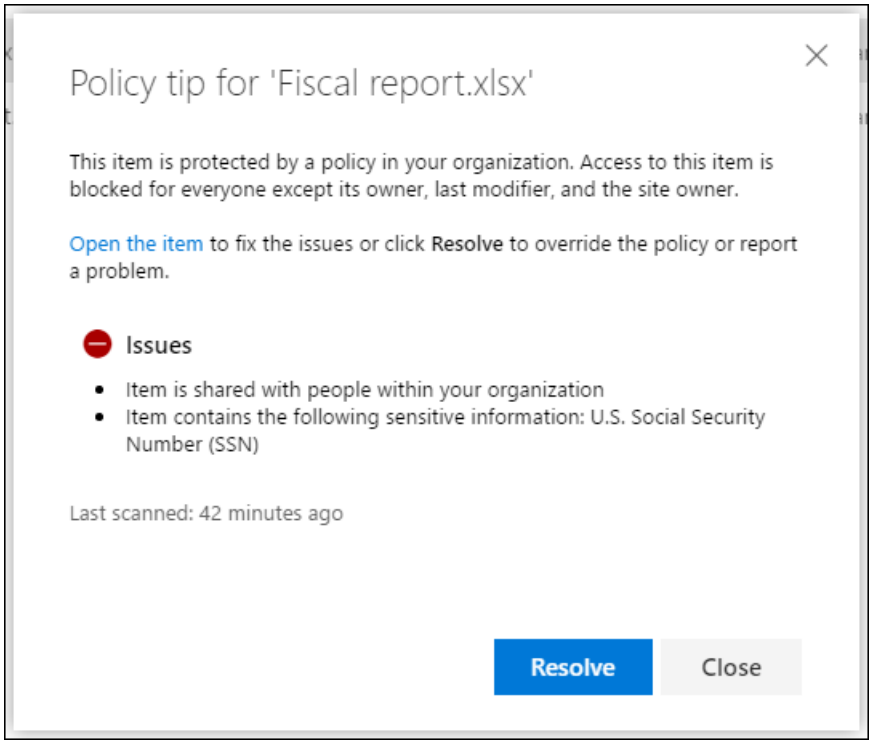
The email can notify the person who sent, shared, or last modified the content and, for site content, the primary site collection administrator and document owner. In addition, you can add or remove whomever you choose from the email notification.

In addition to sending an email notification, a user notification displays a policy tip:

- In Outlook and Outlook on the web.
- For the document on a SharePoint Online or OneDrive for Business site.
- In Excel, PowerPoint, and Word, when the document is stored on a site included in a DLP policy.

The email notification and policy tip explain why content conflicts with a DLP policy. If you choose, the email notification and policy tip can allow users to override a rule by reporting a false positive or providing a business justification. This can help you educate users about your DLP policies and enforce them without preventing people from doing their work. Information about overrides and false positives is also logged for reporting (see below about the DLP reports) and included in the incident reports (next section), so that the compliance officer can regularly review this information.

Here's what a policy tip looks like in a OneDrive for Business account.

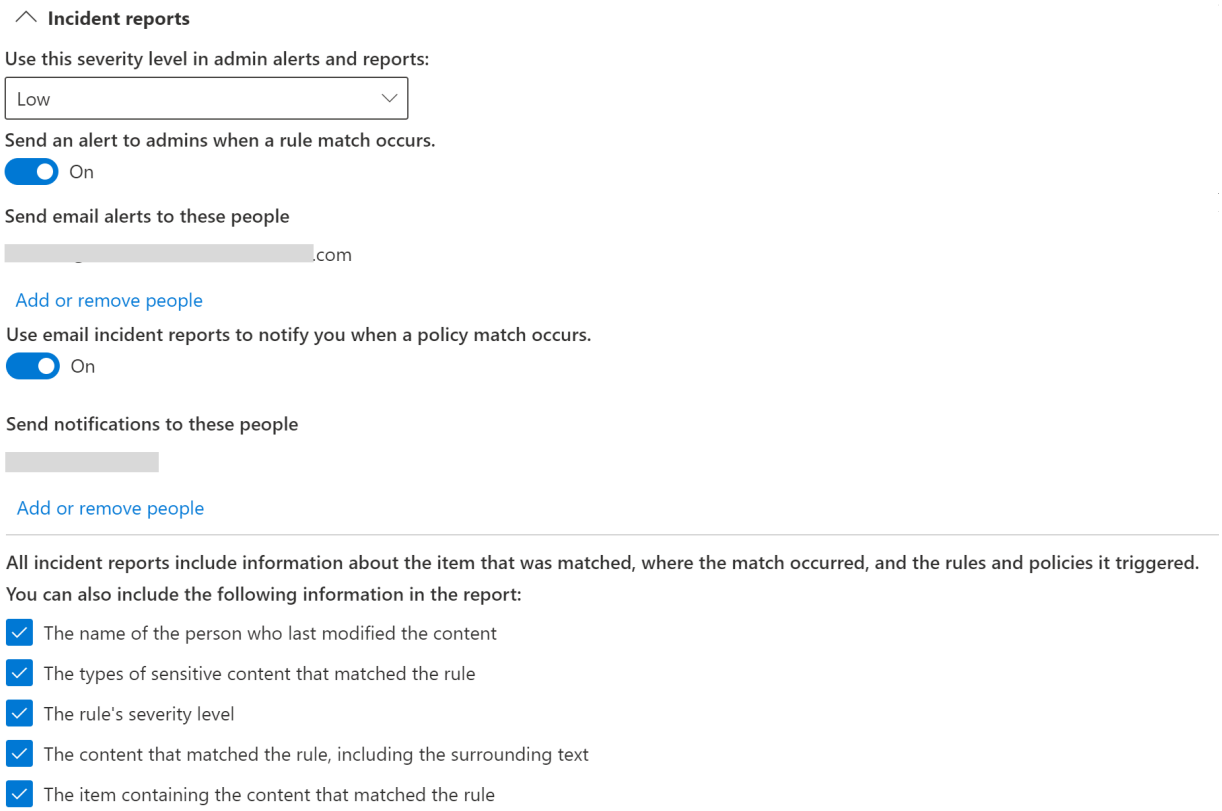


To learn more about user notifications and policy tips in DLP policies, see Use notifications and policy tips.

Alerts and Incident reports

When a rule is matched, you can send an alert email to your compliance officer (or any person(s) you choose) with details of the alert. This alert email will carry a link of the DLP Alerts Management Dashboard which the compliance officer can go to view the details of alert and events. The dashboard contains details of the event that triggered the alert along with details of the DLP policy matched and the sensitive content detected.

In addition, you can also send an incident report with details of the event. This report includes information about the item that was matched, the actual content that matched the rule, and the name of the person who last modified the content. For email messages, the report also includes as an attachment the original message that matches a DLP policy.



DLP scans email differently from items in SharePoint Online or OneDrive for Business. In SharePoint Online and OneDrive for Business, DLP scans existing items as well as new ones and generates an alert and incident report whenever a match is found. In Exchange Online, DLP only scans new email messages and generates a report if there is a policy match. DLP ***does not*** scan or match previously existing email items that are stored in a mailbox or archive.

Grouping and logical operators

Often your DLP policy has a straightforward requirement, such as to identify all content that contains a U.S. Social Security Number. However, in other scenarios, your DLP policy might need to identify more loosely defined data.

For example, to identify content subject to the U.S. Health Insurance Act (HIPAA), you need to look for:

- Content that contains specific types of sensitive information, such as a U.S. Social Security Number or Drug Enforcement Agency (DEA) Number.

  AND

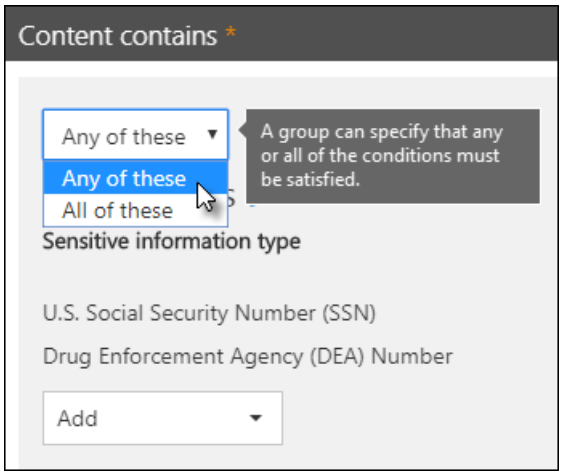
- Content that's more difficult to identify, such as communications about a patient's care or descriptions of medical services provided. Identifying this content requires matching keywords from very large keyword lists, such as the International Classification of Diseases (ICD-9-CM or ICD-10-CM).

You can easily identify such loosely defined data by using grouping and logical operators (AND, OR). When you create a DLP policy, you can:

- Group sensitive information types.
- Choose the logical operator between the sensitive information types within a group and between the groups themselves.

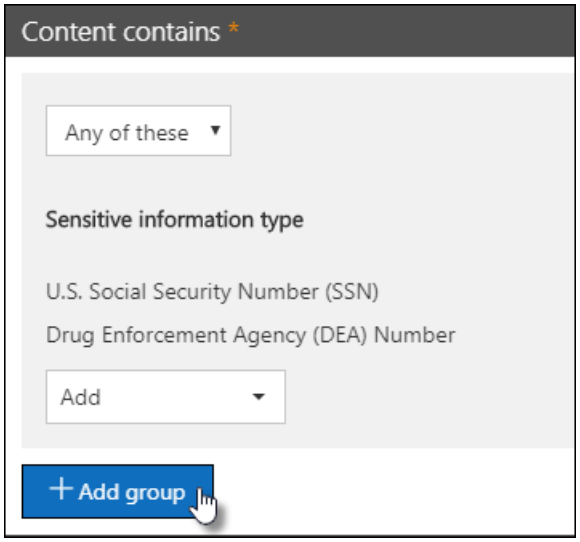
Choosing the operator within a group

Within a group, you can choose whether any or all of the conditions in that group must be satisfied for the content to match the rule.



Adding a group

You can quickly add a group, which can have its own conditions and operator within that group.



Choosing the operator between groups

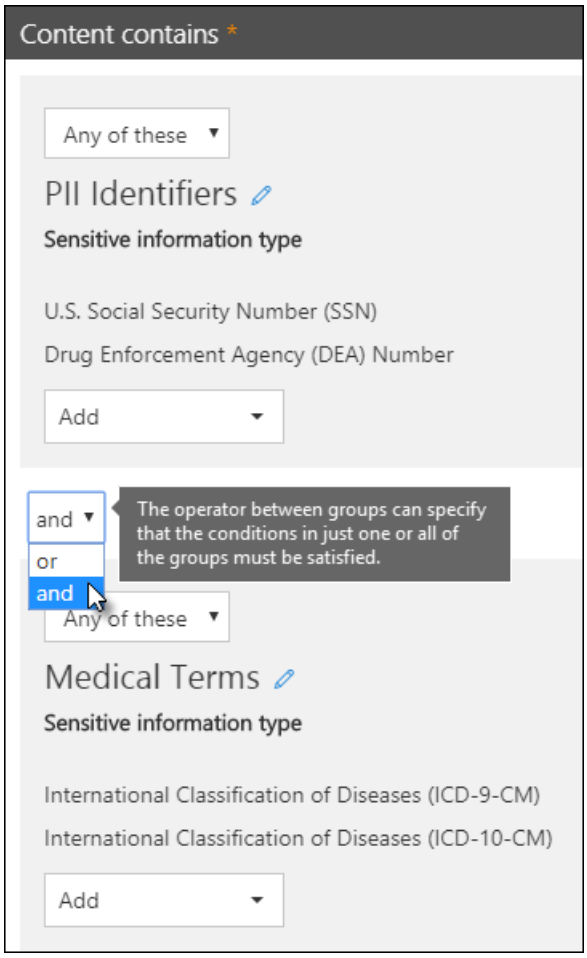
Between groups, you can choose whether the conditions in just one group or all of the groups must be satisfied for the content to match the rule.

For example, the built-in **U.S. HIPAA** policy has a rule that uses an **AND** operator between the groups so that it identifies content that contains:

- from the group **PII Identifiers** (at least one SSN number **OR** DEA number)

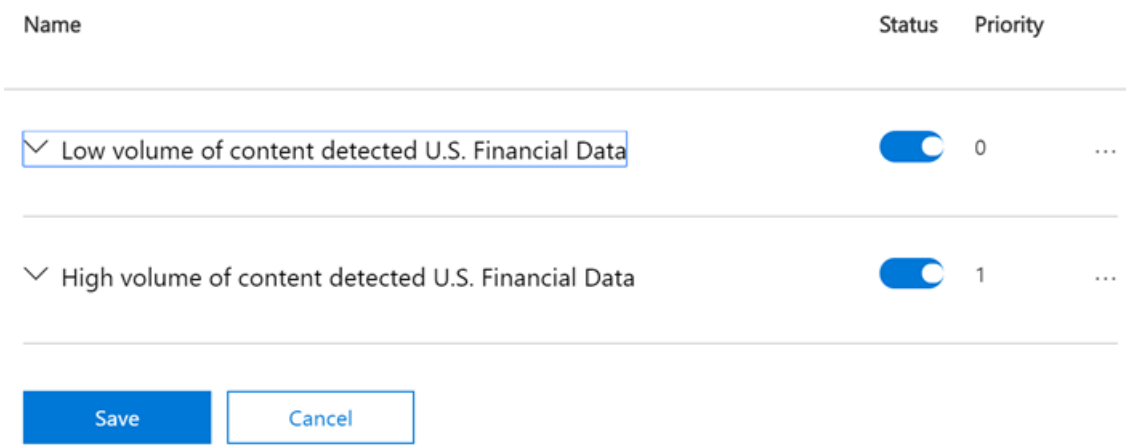
  AND

- from the group **Medical Terms** (at least one ICD-9-CM keyword **OR** ICD-10-CM keyword)

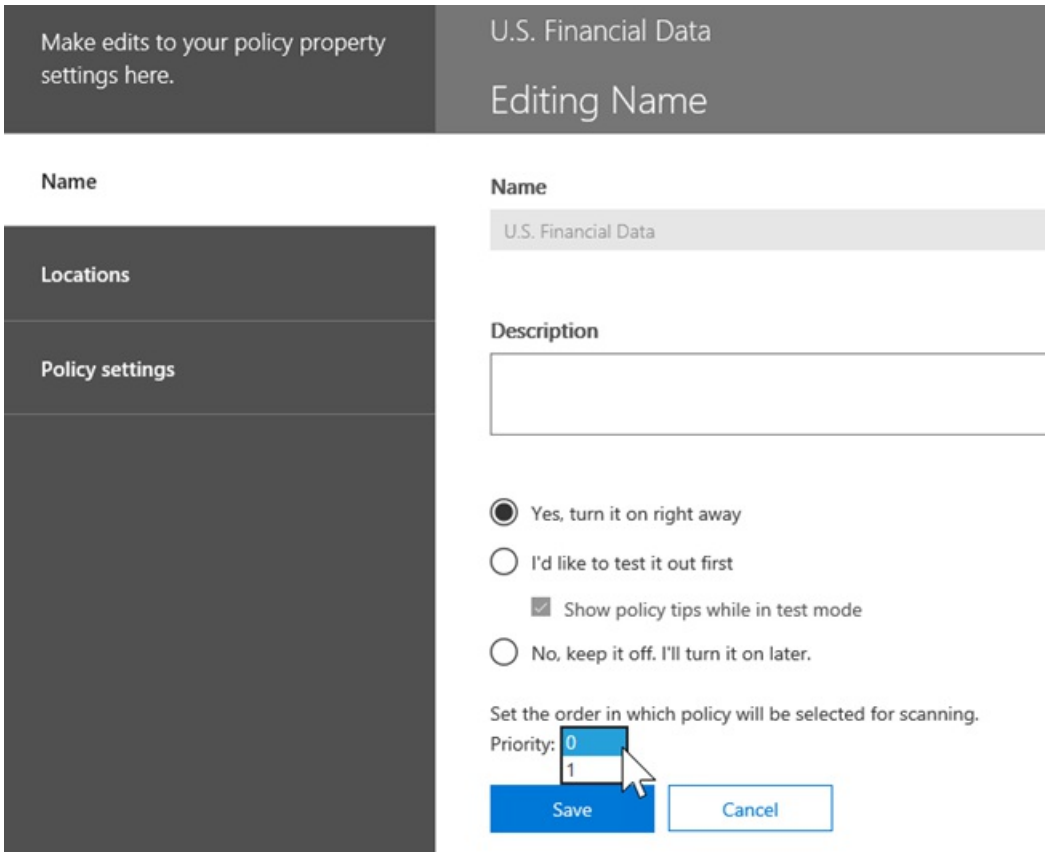


The priority by which rules are processed

When you create rules in a policy, each rule is assigned a priority in the order in which it's created — meaning, the rule created first has first priority, the rule created second has second priority, and so on.



After you have set up more than one DLP policy, you can change the priority of one or more policies. To do that, select a policy, choose **Edit policy**, and use the **Priority** list to specify its priority.



When content is evaluated against rules, the rules are processed in priority order. If content matches multiple rules, the rules are processed in priority order and the most restrictive action is enforced. For example, if content matches all of the following rules, Rule 3 is enforced because it's the highest priority, most restrictive rule:

- Rule 1: only notifies users
- Rule 2: notifies users, restricts access, and allows user overrides
- Rule 3: notifies users, restricts access, and does not allow user overrides
- Rule 4: only notifies users
- Rule 5: restricts access
- Rule 6: notifies users, restricts access, and does not allow user overrides

In this example, note that matches for all of the rules are recorded in the audit logs and shown in the DLP reports, even though only the most restrictive rule is enforced.

Regarding policy tips, note that:

- Only the policy tip from the highest priority, most restrictive rule will be shown. For example, a policy tip from a rule that blocks access to content will be shown over a policy tip from a rule that simply sends a notification. This prevents people from seeing a cascade of policy tips.
- If the policy tips in the most restrictive rule allow people to override the rule, then overriding this rule also overrides any other rules that the content matched.

Tuning rules to make them easier or harder to match

After people create and turn on their DLP policies, they sometimes run into these issues:

- Too much content that **is not** sensitive information matches the rules — in other words, too many false positives.

- Too little content that **is** sensitive information matches the rules. In other words, the protective actions aren't being enforced on the sensitive information.

To address these issues, you can tune your rules by adjusting the instance count and match accuracy to make it harder or easier for content to match the rules. Each sensitive information type used in a rule has both an instance count and match accuracy.

Instance count

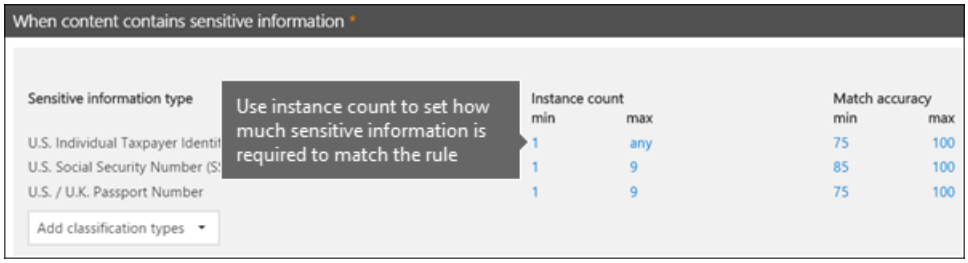
Instance count means simply how many occurrences of a specific type of sensitive information must be present for content to match the rule. For example, content matches the rule shown below if between 1 and 9 unique U.S. or U.K. passport numbers are identified.

Note that the instance count includes only **unique** matches for sensitive information types and keywords. For example, if an email contains 10 occurrences of the same credit card number, those 10 occurrences count as a single instance of a credit card number.

To use instance count to tune rules, the guidance is straightforward:

- To make the rule easier to match, decrease the **min** count and/or increase the **max** count. You can also set **max** to **any** by deleting the numerical value.
- To make the rule harder to match, increase the **min** count.

Typically, you use less restrictive actions, such as sending user notifications, in a rule with a lower instance count (for example, 1-9). And you use more restrictive actions, such as restricting access to content without allowing user overrides, in a rule with a higher instance count (for example, 10-any).



Match accuracy

As described above, a sensitive information type is defined and detected by using a combination of different types of evidence. Commonly, a sensitive information type is defined by multiple such combinations, called patterns. A pattern that requires less evidence has a lower match accuracy (or confidence level), while a pattern that requires more evidence has a higher match accuracy (or confidence level). To learn more about the actual patterns and confidence levels used by every sensitive information type, see Sensitive information type entity definitions.

For example, the sensitive information type named Credit Card Number is defined by two patterns:

- A pattern with 65% confidence that requires:
  - A number in the format of a credit card number.
  - A number that passes the checksum.
- A pattern with 85% confidence that requires:
  - A number in the format of a credit card number.
  - A number that passes the checksum.
  - A keyword or an expiration date in the right format.

You can use these confidence levels (or match accuracy) in your rules. Typically, you use less restrictive actions,

such as sending user notifications, in a rule with lower match accuracy. And you use more restrictive actions, such as restricting access to content without allowing user overrides, in a rule with higher match accuracy.

It's important to understand that when a specific type of sensitive information, such as a credit card number, is identified in content, only a single confidence level is returned:

- If all of the matches are for a single pattern, the confidence level for that pattern is returned.
- If there are matches for more than one pattern (that is, there are matches with two different confidence levels), a confidence level higher than any of the single patterns alone is returned. This is the tricky part. For example, for a credit card, if both the 65% and 85% patterns are matched, the confidence level returned for that sensitive information type is greater than 90% because more evidence means more confidence.

So if you want to create two mutually exclusive rules for credit cards, one for the 65% match accuracy and one for the 85% match accuracy, the ranges for match accuracy would look like this. The first rule picks up only matches of the 65% pattern. The second rule picks up matches with **at least one** 85% match and **can potentially have** other lower-confidence matches.

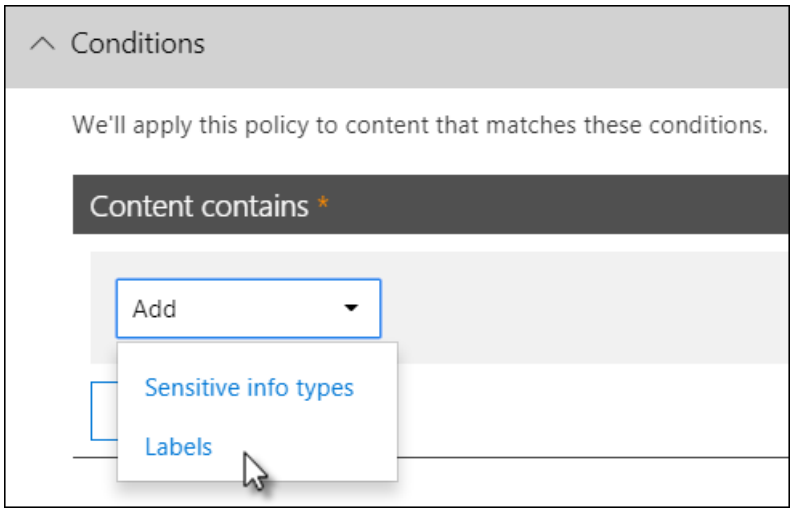
For these reasons, the guidance for creating rules with different match accuracies is:

- The lowest confidence level typically uses the same value for **min** and **max** (not a range).
- The highest confidence level is typically a range from just above the lower confidence level to 100.
- Any in-between confidence levels typically range from just above the lower confidence level to just below the higher confidence level.

Using a retention label as a condition in a DLP policy

When you use a previously created and published retention label as a condition in a DLP policy, there are some things to be aware of:

- The retention label must be created and published before you attempt to use it as a condition in a DLP policy.
- Published retention labels can take from one to seven days to sync. For more information, see When retention labels become available to apply for retention labels published in a retention policy, and How long it takes for retention labels to take effect for retention labels that are auto-published.
- Using a retention label in a policy **is only supported for items in SharePoint and OneDrive***.



You might want to use a retention label in a DLP policy if you have items that are under retention and disposition, and you also want to apply other controls to them, for example:

- You published a retention label named **tax year 2018**, which when applied to tax documents from 2018 that are stored in SharePoint retains them for 10 years then disposes of them. You also don't want those items being shared outside your organization, which you can do with a DLP policy.

> **IMPORTANT**
> You'll get this error if you specify a retention label as a condition in a DLP policy and you also include Exchange and/or Teams as a location: **"Protecting labeled content in email and teams messages isn't supported. Either remove the label below or turn off Exchange and Teams as a location."** This is because Exchange transport does not evaluate the label metadata during message submission and delivery.

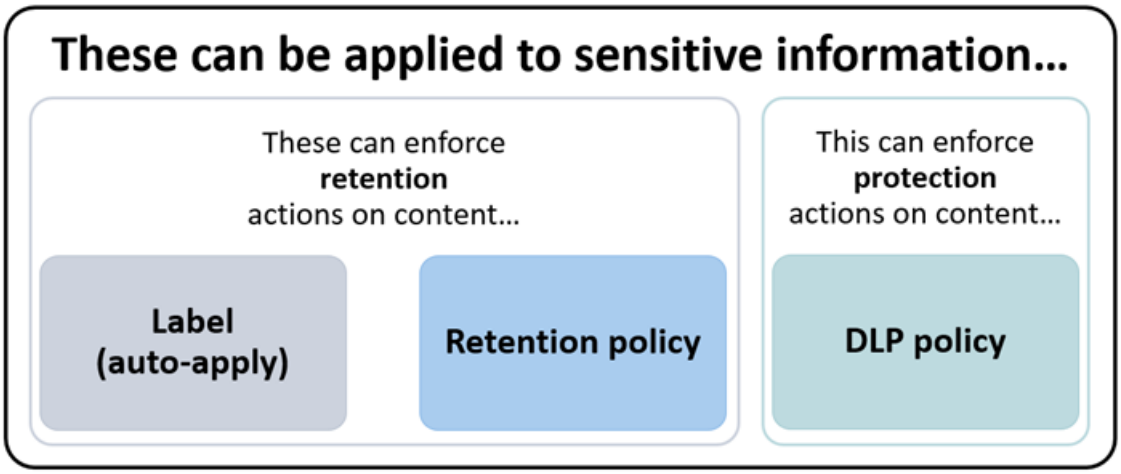
Using a sensitivity label as a condition in a DLP policy

Sensitivity label as a condition in DLP policies is currently in preview. Learn more.

How this feature relates to other features

Several features can be applied to content containing sensitive information:

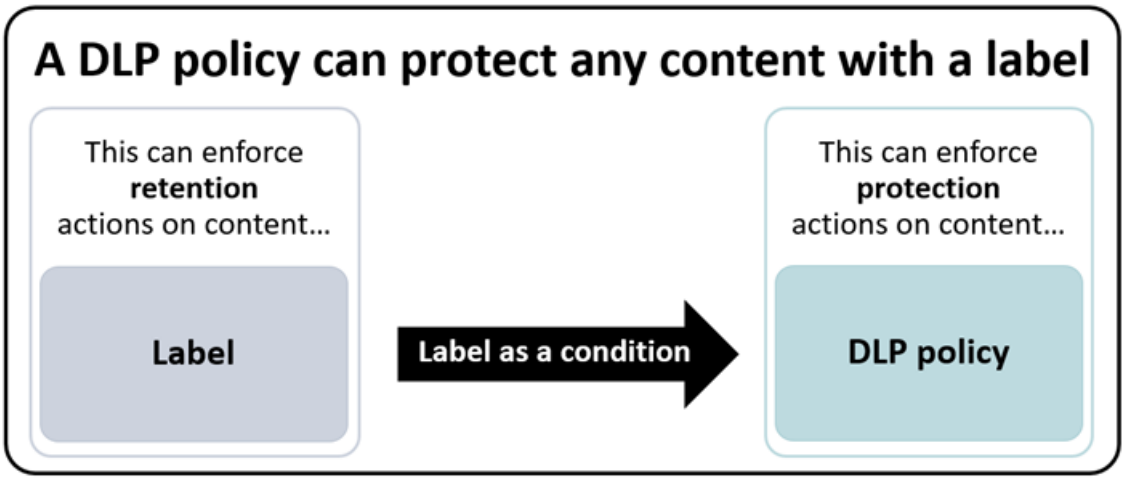
- A retention label and a retention policy can both enforce **retention** actions on this content.
- A DLP policy can enforce **protection** actions on this content. And before enforcing these actions, a DLP policy can require other conditions to be met in addition to the content containing a label.



Note that a DLP policy has a richer detection capability than a label or retention policy applied to sensitive information. A DLP policy can enforce protective actions on content containing sensitive information, and if the sensitive information is removed from the content, those protective actions are undone the next time the

content's scanned. But if a retention policy or label is applied to content containing sensitive information, that's a one-time action that won't be undone even if the sensitive information is removed.

By using a label as a condition in a DLP policy, you can enforce both retention and protection actions on content with that label. You can think of content containing a label exactly like content containing sensitive information - both a label and a sensitive information type are properties used to classify content, so that you can enforce actions on that content.



Simple settings vs. advanced settings

When you create a DLP policy, you'll choose between simple or advanced settings:

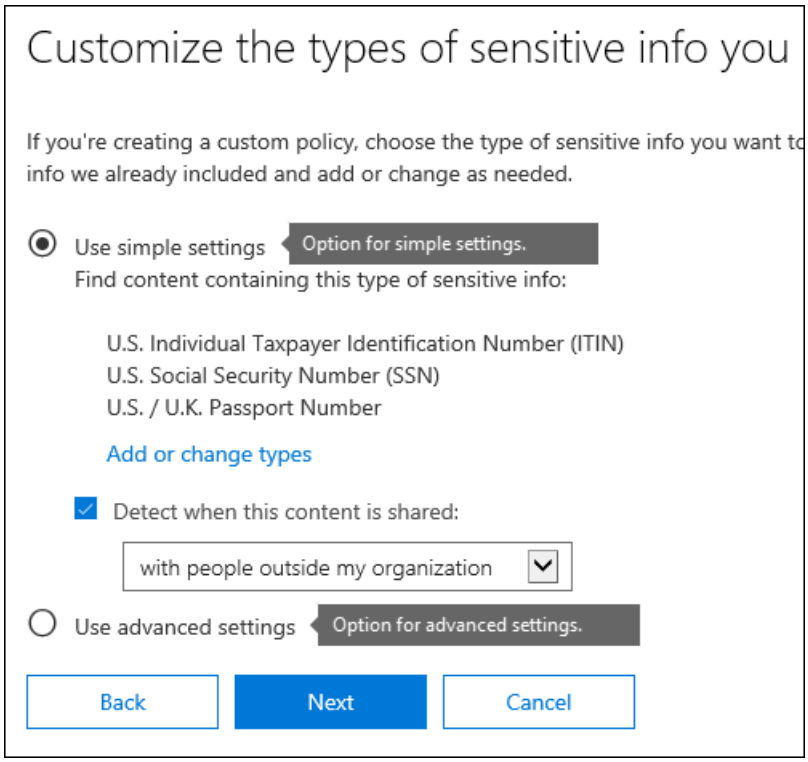
- **Simple settings** make it easy to create the most common type of DLP policy without using the rule editor to create or modify rules.
- **Advanced settings** use the rule editor to give you complete control over every setting for your DLP policy.

Don't worry, under the covers, simple settings and advanced settings work exactly the same, by enforcing rules comprised of conditions and actions -- only with simple settings, you don't see the rule editor. It's a quick way to create a DLP policy.

Simple settings

By far, the most common DLP scenario is creating a policy to help protect content containing sensitive information from being shared with people outside your organization, and taking an automatic remediating action such as restricting who can access the content, sending end-user or admin notifications, and auditing the event for later investigation. People use DLP to help prevent the inadvertent disclosure of sensitive information.

To simplify achieving this goal, when you create a DLP policy, you can choose **Use simple settings**. These settings provide everything you need to implement the most common DLP policy, without having to go into the rule editor.

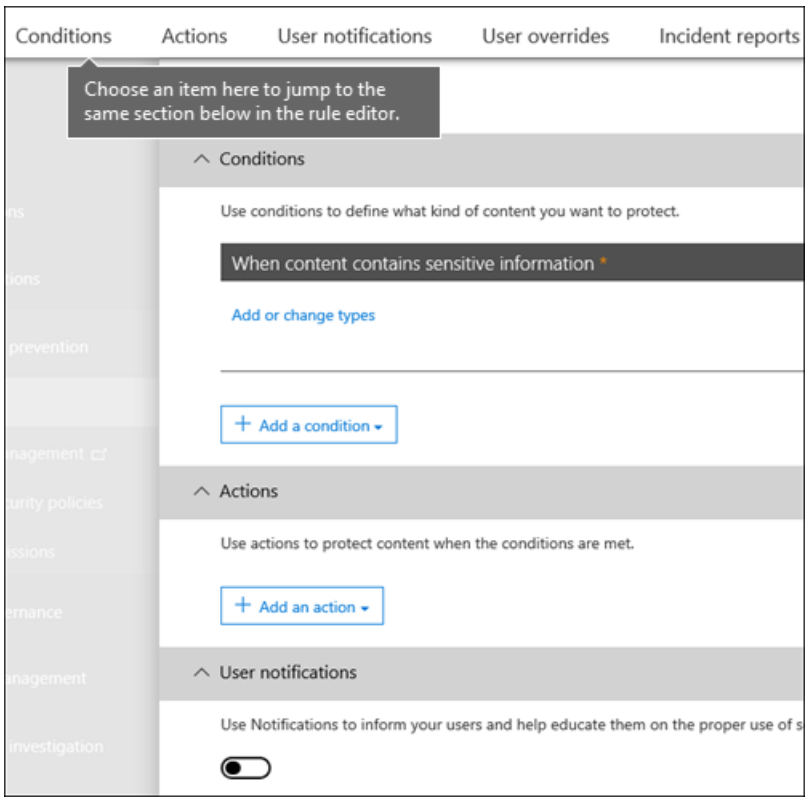


Advanced settings

If you need to create more customized DLP policies, you can choose **Use advanced settings**.

The advanced settings present you with the rule editor, where you have full control over every possible option, including the instance count and match accuracy (confidence level) for each rule.

To jump to a section quickly, click an item in the top navigation of the rule editor to go to that section below.

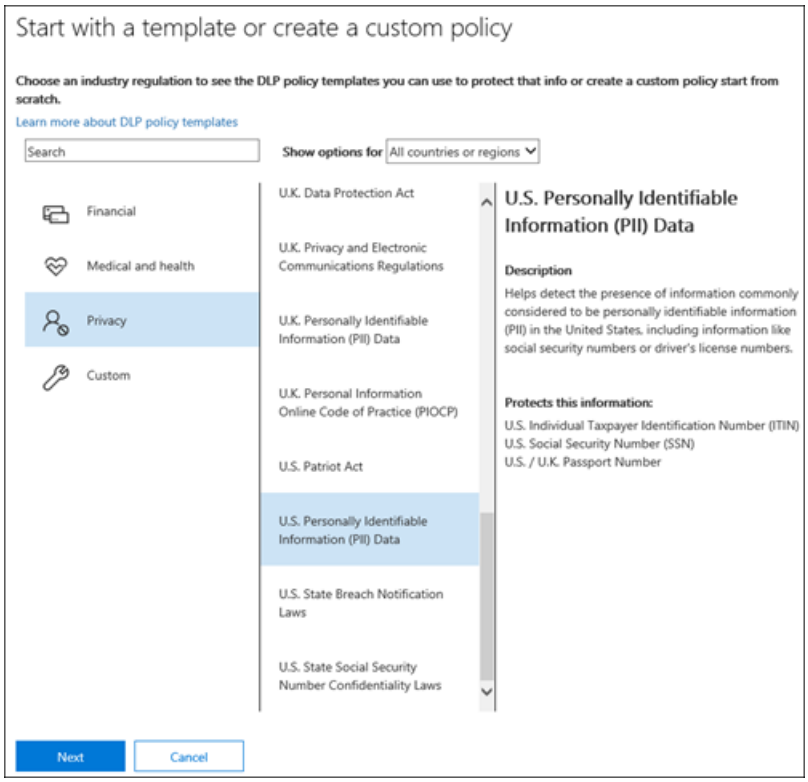


DLP policy templates

The first step in creating a DLP policy is choosing what information to protect. By starting with a DLP template, you save the work of building a new set of rules from scratch, and figuring out which types of information should be included by default. You can then add to or modify these requirements to fine tune the rule to meet

your organization's specific requirements.

A preconfigured DLP policy template can help you detect specific types of sensitive information, such as HIPAA data, PCI-DSS data, Gramm-Leach-Bliley Act data, or even locale-specific personally identifiable information (P.I.). To make it easy for you to find and protect common types of sensitive information, the policy templates included in Microsoft 365 already contain the most common sensitive information types necessary for you to get started.



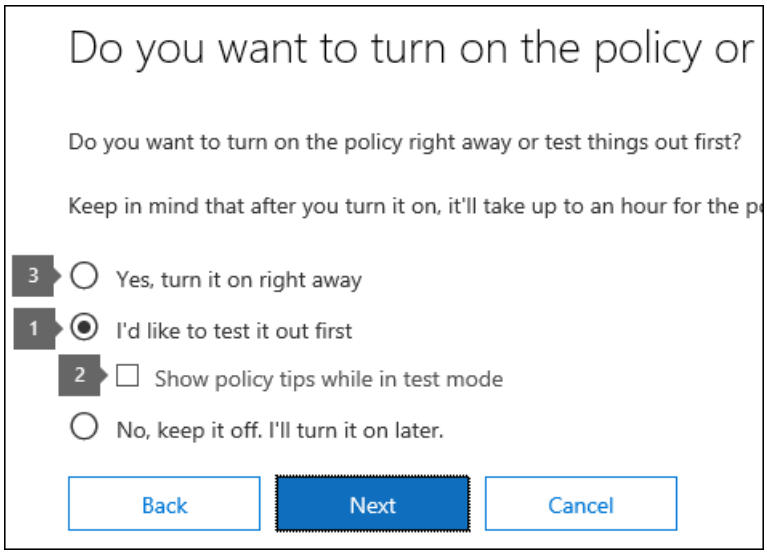
Your organization may also have its own specific requirements, in which case you can create a DLP policy from scratch by choosing the **Custom policy** option. A custom policy is empty and contains no premade rules.

Roll out DLP policies gradually with test mode

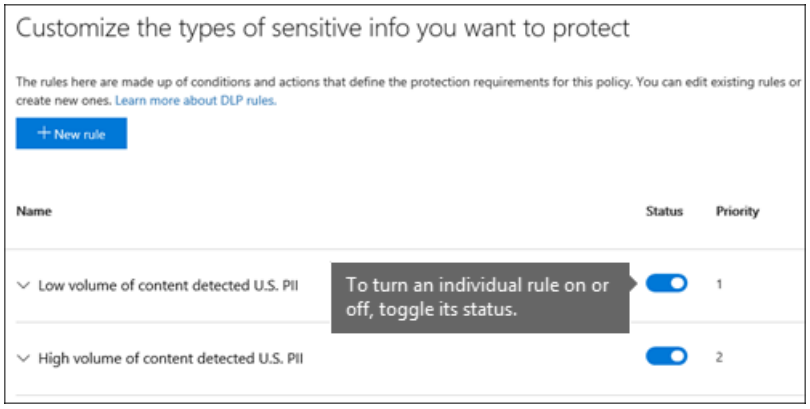
When you create your DLP policies, you should consider rolling them out gradually to assess their impact and test their effectiveness before fully enforcing them. For example, you don't want a new DLP policy to unintentionally block access to thousands of documents that people require access to in order to get their work done.

If you're creating DLP policies with a large potential impact, we recommend following this sequence:

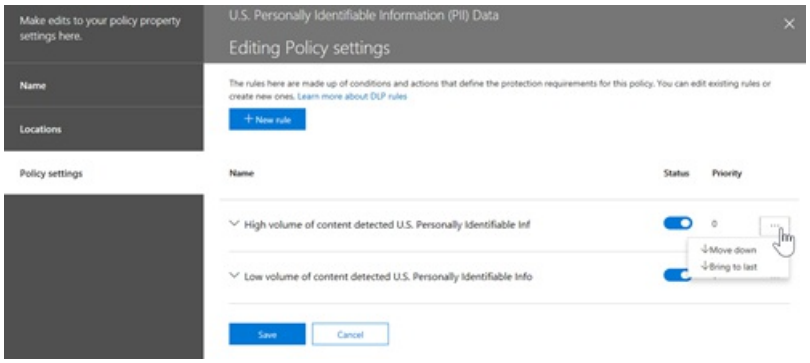
1. **Start in test mode without Policy Tips** and then use the DLP reports and any incident reports to assess the impact. You can use DLP reports to view the number, location, type, and severity of policy matches. Based on the results, you can fine tune the rules as needed. In test mode, DLP policies will not impact the productivity of people working in your organization.
2. **Move to Test mode with notifications and Policy Tips** so that you can begin to teach users about your compliance policies and prepare them for the rules that are going to be applied. At this stage, you can also ask users to report false positives so that you can further refine the rules.
3. **Start full enforcement on the policies** so that the actions in the rules are applied and the content's protected. Continue to monitor the DLP reports and any incident reports or notifications to make sure that the results are what you intend.



You can turn off a DLP policy at any time, which affects all rules in the policy. However, each rule can also be turned off individually by toggling its status in the rule editor.



You can also change the priority of multiple rules in a policy. To do that, open a policy for editing. In a row for a rule, choose the ellipses (...), and then choose an option, such as **Move down** or **Bring to last**.



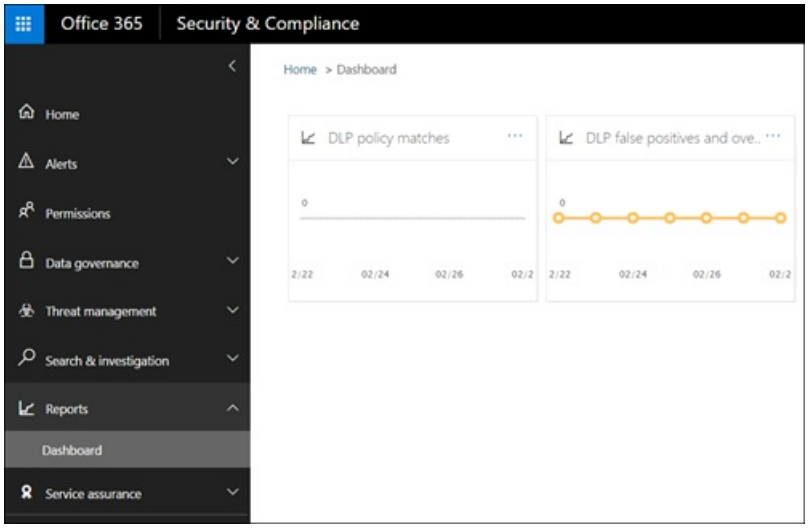
DLP reports

After you create and turn on your DLP policies, you'll want to verify that they're working as you intended and helping you stay compliant. With DLP reports, you can quickly view the number of DLP policy and rule matches over time, and the number of false positives and overrides. For each report, you can filter those matches by location, time frame, and even narrow it down to a specific policy, rule, or action.

With the DLP reports, you can get business insights and:

- Focus on specific time periods and understand the reasons for spikes and trends.
- Discover business processes that violate your organization's compliance policies.
- Understand any business impact of the DLP policies.

In addition, you can use the DLP reports to fine tune your DLP policies as you run them.



How DLP policies work

DLP detects sensitive information by using deep content analysis (not just a simple text scan). This deep content analysis uses keyword matches, dictionary matches, the evaluation of regular expressions, internal functions, and other methods to detect content that matches your DLP policies. Potentially only a small percentage of your data is considered sensitive. A DLP policy can identify, monitor, and automatically protect just that data, without impeding or affecting people who work with the rest of your content.

Policies are synced

After you create a DLP policy in the Security & Compliance Center, it's stored in a central policy store, and then synced to the various content sources, including:

- Exchange Online, and from there to Outlook on the web and Outlook.
- OneDrive for Business sites.
- SharePoint Online sites.
- Office desktop programs (Excel, PowerPoint, and Word).
- Microsoft Teams channels and chat messages.

After the policy's synced to the right locations, it starts to evaluate content and enforce actions.

Policy evaluation in OneDrive for Business and SharePoint Online sites

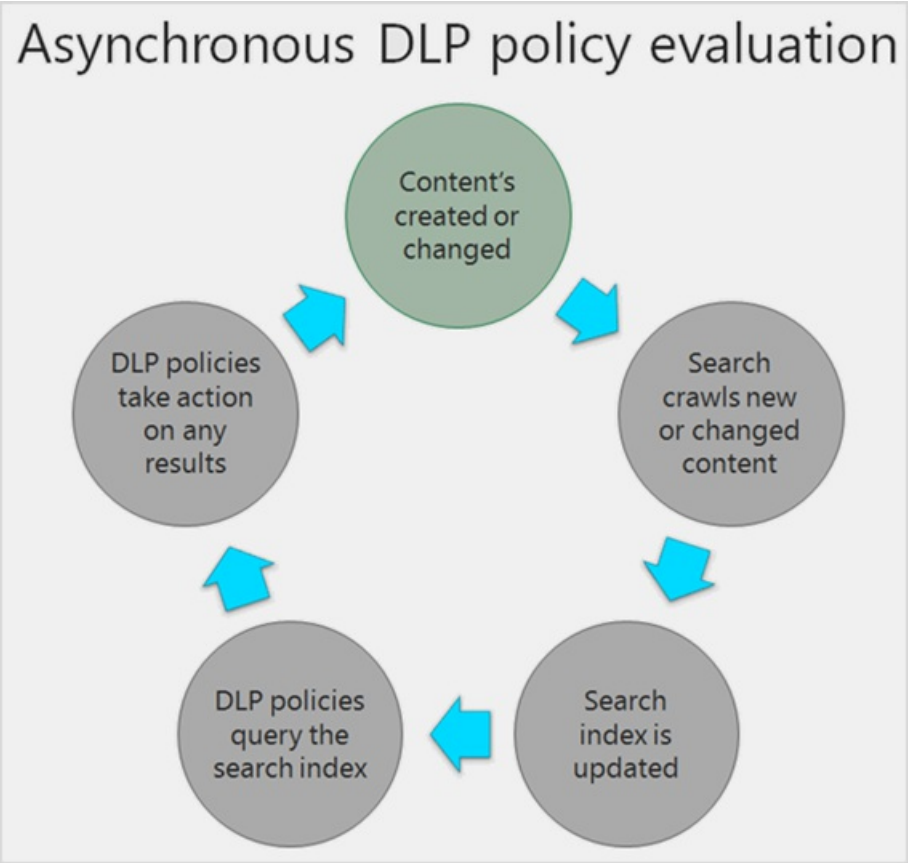
Across all of your SharePoint Online sites and OneDrive for Business sites, documents are constantly changing — they're continually being created, edited, shared, and so on. This means documents can conflict or become compliant with a DLP policy at any time. For example, a person can upload a document that contains no sensitive information to their team site, but later, a different person can edit the same document and add sensitive information to it.

For this reason, DLP policies check documents for policy matches frequently in the background. You can think of this as asynchronous policy evaluation.

How it works

As people add or change documents in their sites, the search engine scans the content, so that you can search for it later. While this is happening, the content's also scanned for sensitive information and to check if it's shared. Any sensitive information that's found is stored securely in the search index, so that only the compliance team can access it, but not typical users. Each DLP policy that you've turned on runs in the background (asynchronously), checking search frequently for any content that matches a policy, and applying actions to

protect it from inadvertent leaks.



Finally, documents can conflict with a DLP policy, but they can also become compliant with a DLP policy. For example, if a person adds credit card numbers to a document, it might cause a DLP policy to block access to the document automatically. But if the person later removes the sensitive information, the action (in this case, blocking) is automatically undone the next time the document is evaluated against the policy.

DLP evaluates any content that can be indexed. For more information on what file types are crawled by default, see Default crawled file name extensions and parsed file types in SharePoint Server.

> **NOTE**
> External sharing of new files in SharePoint can be blocked by default until at least one DLP policy scans the new item. See, Mark new files as sensitive by default for detailed information.

Policy evaluation in Exchange Online, Outlook, and Outlook on the web

When you create a DLP policy that includes Exchange Online as a location, the policy's synced from the Office 365 Security & Compliance Center to Exchange Online, and then from Exchange Online to Outlook on the web and Outlook.

When a message is being composed in Outlook, the user can see policy tips as the content being created is evaluated against DLP policies. And after a message is sent, it's evaluated against DLP policies as a normal part of mail flow, along with Exchange mail flow rules (also known as transport rules) and DLP policies created in the Exchange admin center. DLP policies scan both the message and any attachments.

Policy evaluation in the Office desktop programs

Excel, PowerPoint, and Word include the same capability to identify sensitive information and apply DLP policies as SharePoint Online and OneDrive for Business. These Office programs sync their DLP policies directly from the central policy store, and then continuously evaluate the content against the DLP policies when people work with documents opened from a site that's included in a DLP policy.

DLP policy evaluation in Office is designed not to affect the performance of the programs or the productivity of people working on content. If they're working on a large document, or the user's computer is busy, it might take a few seconds for a policy tip to appear.

Policy evaluation in Microsoft Teams

When you create a DLP policy that includes Microsoft Teams as a location, the policy's synced from the Office 365 Security & Compliance Center to user accounts and Microsoft Teams channels and chat messages. Depending on how DLP policies are configured, when someone attempts to share sensitive information in a Microsoft Teams chat or channel message, the message can be blocked or revoked. And, documents that contain sensitive information and that are shared with guests (external users) won't open for those users. To learn more, see Data loss prevention and Microsoft Teams.

Permissions

Members of your compliance team who will create DLP policies need permissions to the Security & Compliance Center. By default, your tenant admin will have access to this location and can give compliance officers and other people access to the Security & Compliance Center, without giving them all of the permissions of a tenant admin. To do this, we recommend that you:

1. Create a group in Microsoft 365 and add compliance officers to it.
2. Create a role group on the **Permissions** page of the Security & Compliance Center.
3. While creating the role group, use the **Choose Roles** section to add the following role to the Role Group: **DLP Compliance Management**.
4. Use the **Choose Members** section to add the Microsoft 365 group you created before to the role group.

You can also create a role group with view-only privileges to the DLP policies and DLP reports by granting the **View-Only DLP Compliance Management** role.

For more information, see Give users access to the Office 365 Compliance Center.

These permissions are required only to create and apply a DLP policy. Policy enforcement does not require access to the content.

Find the DLP cmdlets

To use most of the cmdlets for the Security & Compliance Center, you need to:

1. Connect to the Office 365 Security & Compliance Center using remote PowerShell.
2. Use any of these policy-and-compliance-dlp cmdlets.

However, DLP reports need pull data from across Microsoft 365, including Exchange Online. For this reason, **the cmdlets for the DLP reports are available in Exchange Online Powershell -- not in Security & Compliance Center Powershell**. Therefore, to use the cmdlets for the DLP reports, you need to:

1. Connect to Exchange Online using remote PowerShell.
2. Use any of these cmdlets for the DLP reports:
   - Get-DlpDetectionsReport
   - Get-DlpDetailReport

Learn about Microsoft 365 Endpoint data loss prevention

2/18/2021 • 4 minutes to read • Edit Online

You can use Microsoft 365 data loss prevention (DLP) to monitor the actions that are being taken on items you've determined to be sensitive and to help prevent the unintentional sharing of those items. For more information on DLP, see Overview of data loss prevention.

Endpoint data loss prevention (Endpoint DLP) extends the activity monitoring and protection capabilities of DLP to sensitive items that are on Windows 10 devices. Once devices are onboarded into the Microsoft 365 compliance solutions, the information about what users are doing with sensitive items is made visible in activity explorer and you can enforce protective actions on those items via DLP policies.

Endpoint activities you can monitor and take action on

Microsoft Endpoint DLP enables you to audit and manage the following types of activities users take on sensitive items on devices running Windows 10.

ACTIVITY	DESCRIPTION	AUDITABLE/RESTICTABLE
upload to cloud service, or access by unallowed browsers	Detects when a user attempts to upload an item to a restricted service domain or access an item through a browser. If they are using a browser that is listed in DLP as an being an unallowed browser, the upload activity will be blocked and the user is redirected to use Edge Chromium. Edge Chromium will then either allow or block the upload or access based on the DLP policy configuration	auditable and restrictable
copy to other app	Detects when a user attempts to copy information from a protected item and then paste it into another app, process or item. Copying and pasting information within the same app, process, or item is not detected by this activity.	auditable and restrictable
copy to USB removable media	Detects when a user attempts to copy an item or information to removable media or USB device.	auditable and restrictable
copy to a network share	Detects when a user attempts to copy an item to a network share or mapped network drive	auditable and restrictable
print a document	Detects when a user attempts to print a protected item to a local or network printer.	auditable and restrictable

ACTIVITY	DESCRIPTION	AUDITABLE/RESTICTABLE
create an item	Detects when a user creates an item	auditable
rename an item	Detects when a user renames an item	auditable

Monitored files

Endpoint DLP supports monitoring of these file types:

- Word files
- PowerPoint files
- Excel files
- PDF files
- .csv files
- .tsv files
- .txt files
- .rtf files
- .c files
- .class files
- .cpp files
- .cs files
- .h files
- .java files

By default, endpoint DLP audits the activities for these file types, even if there isn't a policy match. If you only want monitoring data from policy matches, you can turn off the **Always audit file activity for devices** in the endpoint DLP global settings. No matter what, activities on any Word, PowerPoint, Excel, PDF, and .csv file are always audited.

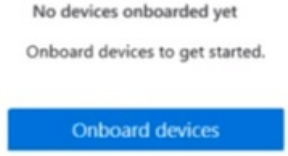
Endpoint DLP monitors activity-based on MIME type, so activities will be captured even if the file extension is changed.

What's different in Endpoint DLP

There are a few extra concepts that you need to be aware of before you dig into Endpoint DLP.

Enabling Device management

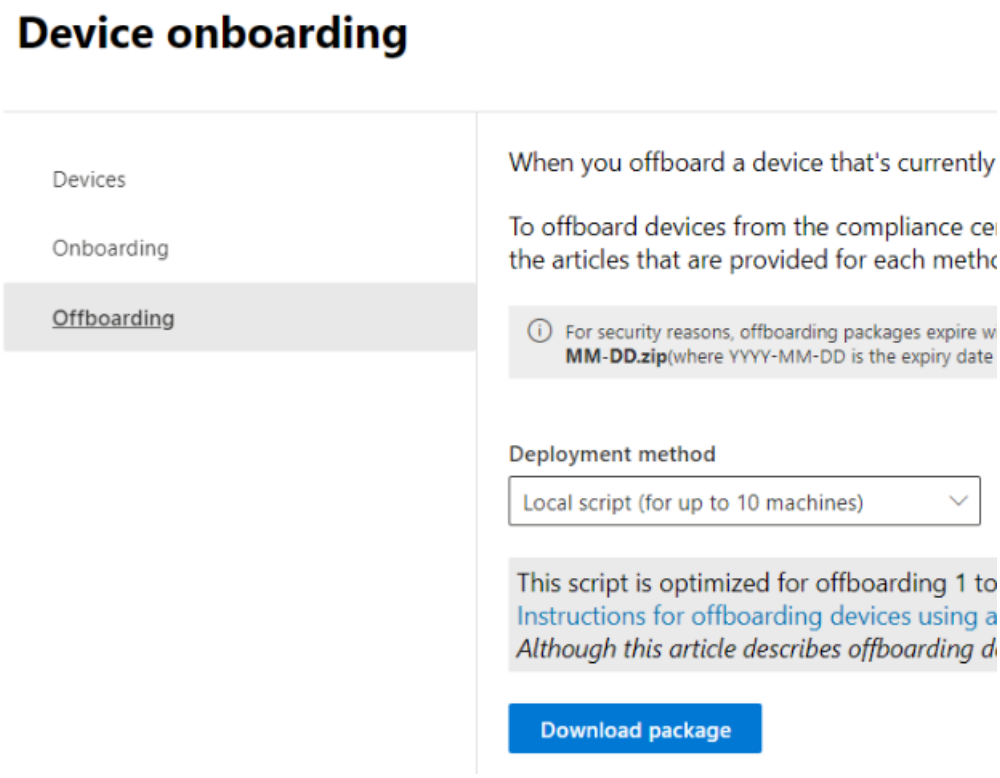
Device management is the functionality that enables the collection of telemetry from devices and brings it into Microsoft 365 compliance solutions like Endpoint DLP and Insider Risk management. You'll need to onboard all devices you want to use as locations in DLP policies.



Onboarding and offboarding are handled via scripts you download from the Device management center. The center has custom scripts for each of these deployment methods:

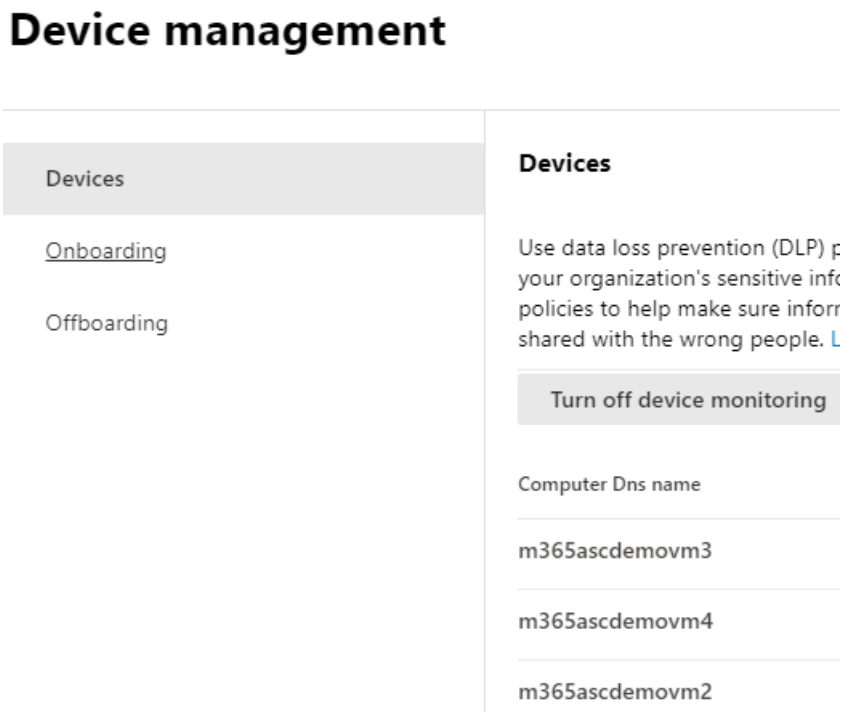
- local script (up to 10 machines)
- Group policy

- System Center Configuration Manager (version 1610 or later)
- Mobile Device Management/Microsoft Intune
- VDI onboarding scripts for non-persistent machines



Use the procedures in Getting started with Microsoft 365 Endpoint DLP to onboard devices.

If you have onboarded devices through Microsoft Defender for Endpoint, those devices will automatically show up in the list of devices.



Viewing Endpoint DLP data

You can view alerts related to DLP policies enforced on endpoint devices by going to the DLP Alerts Management Dashboard.

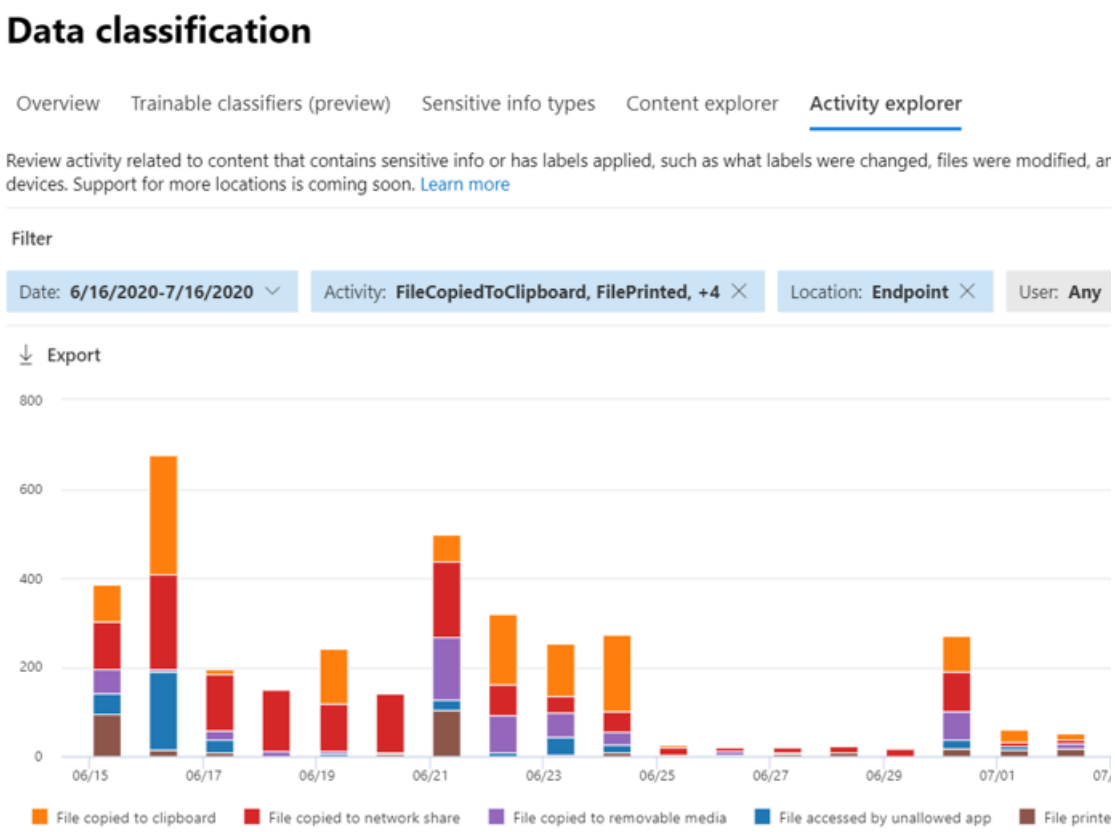
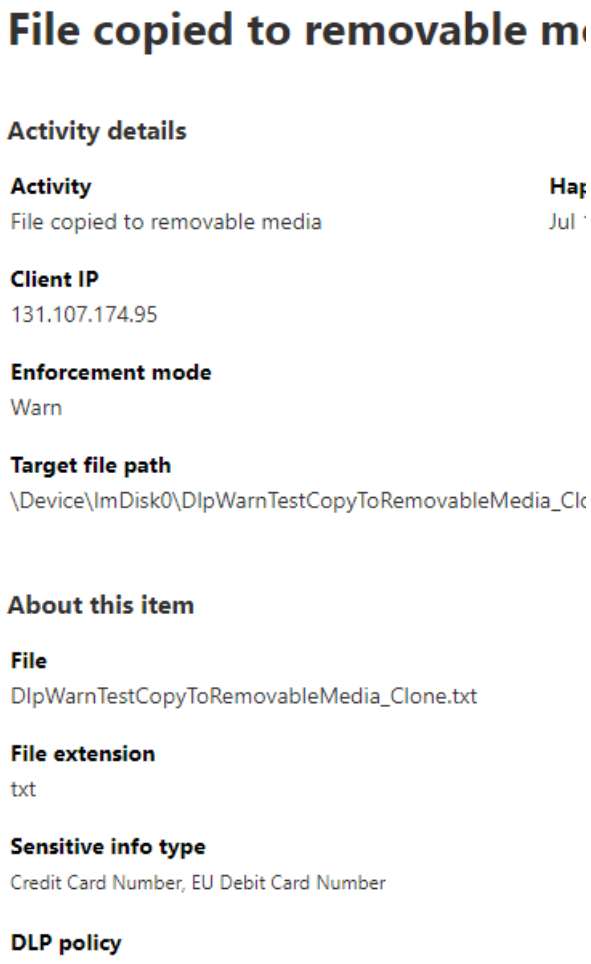
Once a device is onboarded, information about audited activities flows into Activity explorer even before you configure and deploy any DLP policies that have devices as a location.



Endpoint DLP collects extensive information on audited activity.

For example, if a file is copied to removable USB media, you'd see these attributes in the activity details:

- activity type
- client IP
- target file path
- happened timestamp
- file name
- user
- file extension
- file size
- sensitive information type (if applicable)
- sha1 value
- sha256 value
- previous file name
- location
- parent
- filepath
- source location type
- platform
- device name
- destination location type
- application that performed the copy
- Microsoft Defender for Endpoint device ID (if applicable)
- removable media device manufacturer
- removable media device model
- removable media device serial number



Next steps

Now that you've learned about Endpoint DLP, your next steps are:

1. Getting started with Microsoft Endpoint data loss prevention
2. Using Microsoft Endpoint data loss prevention

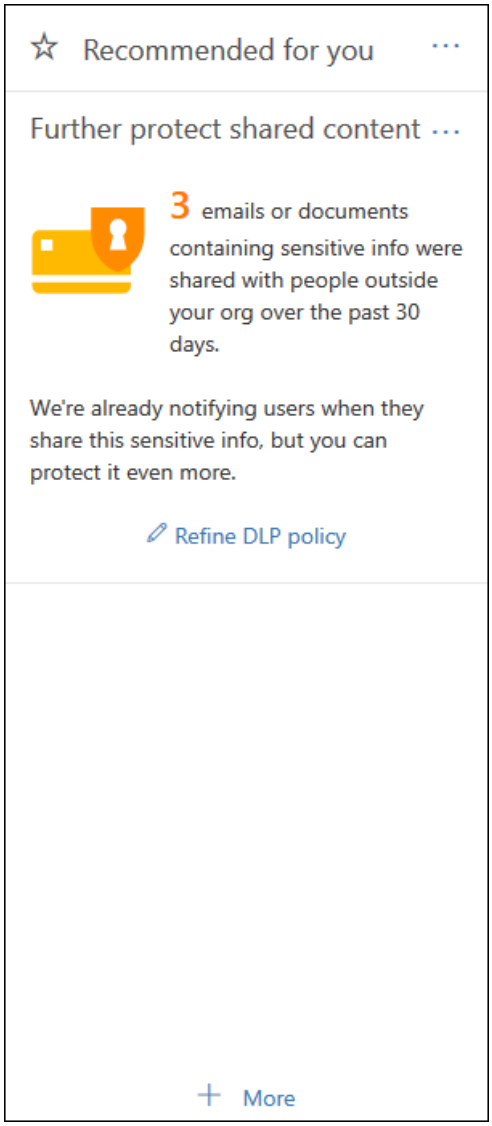
Get started with the default DLP policy

11/2/2020 • 3 minutes to read • Edit Online

Before you even create your first data loss prevention (DLP) policy, DLP is helping to protect your sensitive information with a default policy. This default policy and its recommendation (shown below) help keep your sensitive content secure by notifying you when email or documents containing a credit card number were shared with someone outside your organization. You'll see this recommendation on the **Home** page of the Security & Compliance Center.

You can use this widget to quickly view when and how much sensitive information was shared, and then refine the default DLP policy in just a click or two. You can also edit the default DLP policy at any time because it's fully customizable. Note that if you don't see the recommendation at first, try clicking **+More** at the bottom of the **Recommended for you** section.



View the report and refine the default DLP policy

When the widget shows you that users have shared sensitive information with people outside your organization, choose **Refine DLP policy** at the bottom.

The detailed report shows you when and how much content containing credit card numbers was shared in the past 30 days. Note that rule matches can take up to 48 hours to show up in the widget.

To help protect the sensitive information, the default DLP policy:

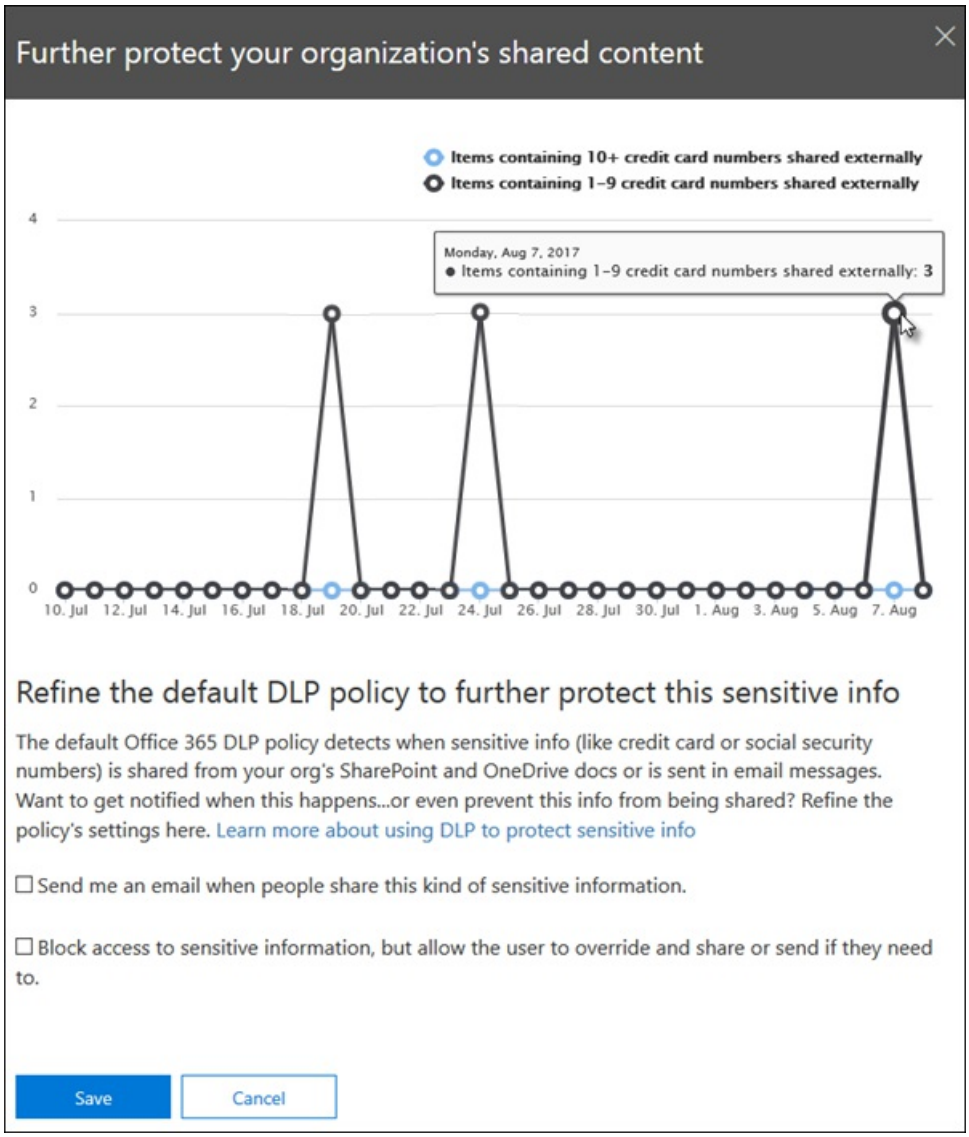
- Detects when content in Exchange, SharePoint, and OneDrive that contains at least one credit card number is shared with people outside your organization.
- Shows a policy tip and sends an email notification to users when they attempt to share this sensitive information with people outside your organization. For more information on these options, see Send email notifications and show policy tips for DLP policies.
- Generates detailed activity reports so that you can track things like who shared the content with people outside your organization and when they did it. You can use the DLP reports and audit log data (where **Activity** = **DLP**) to see this information.

To quickly refine the default DLP policy, you can choose to have it:

- Send you an incident report email when users share this sensitive information with people outside your organization.
- Add other users to the email incident report.
- Block access to the content containing the sensitive information, but allow the user to override and share or send if they need to.

For more information on incident reports or restricting access, see Overview of data loss prevention policies.

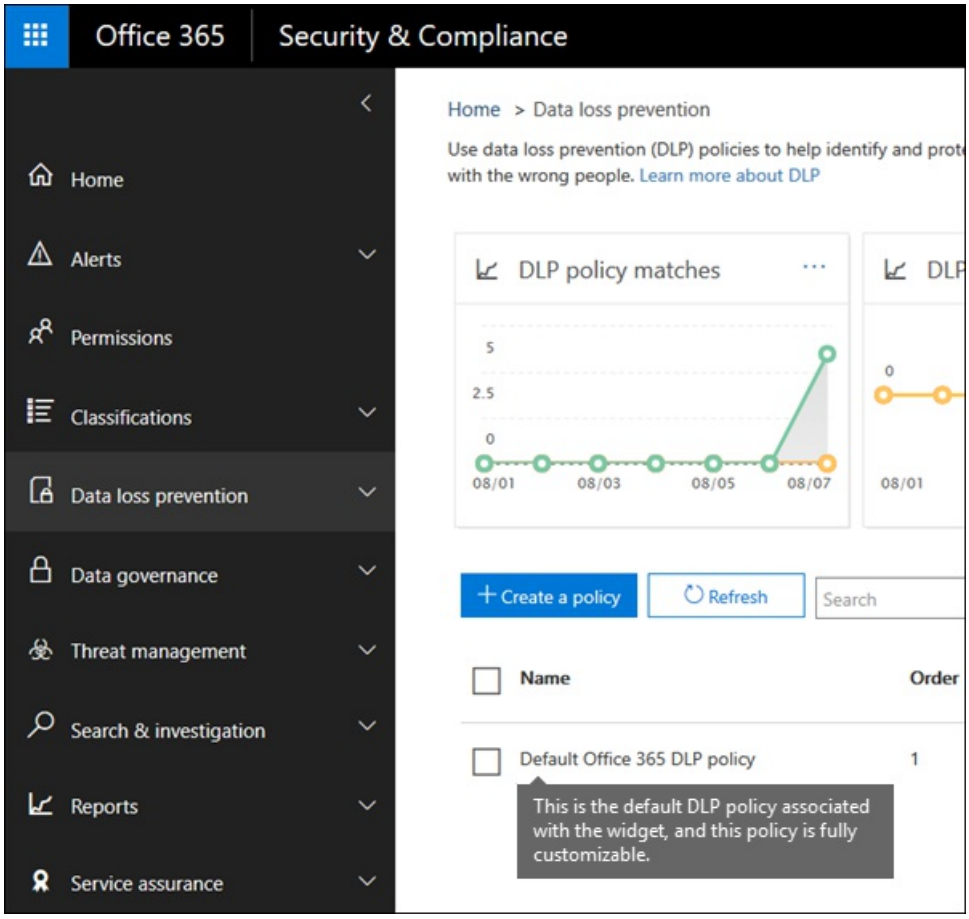
If you want to change these options later, you can edit the default DLP policy at any time - see the next section.



Edit the default DLP policy

This policy is named **Default DLP policy** and appears under **Data loss prevention** on the **Policy** page of the Security & Compliance Center.

This policy is fully customizable, the same as any DLP policy that you create yourself from scratch. You can also turn off or delete the policy, so that your users no longer receive policy tips or email notifications.



When the widget does and does not appear

The widget named **Further protect shared content** appears in the **Recommended for you** section of the **Home** page of the Security & Compliance Center.

This widget appears only when:

- There are no data loss prevention policies in the Security & Compliance Center or Exchange admin center. This widget is intended to help you get started with DLP, so it doesn't appear if you already have DLP policies.
- Content containing least one credit card has been shared with someone outside your organization in the past 30 days.

Note that rule matches can take up to 48 hours to be available to the widget, so after sensitive information shared externally is detected, it may take up to two days for the recommendation to appear.

Finally, after you use the widget to refine the default DLP policy, the widget disappears from the **Home** page.

Create a DLP policy from a template

5/20/2020 • 10 minutes to read • Edit Online

The easiest, most common way to get started with DLP policies is to use one of the templates included in Office 365. You can use one of these templates as is, or customize the rules to meet your organization's specific compliance requirements.

Microsoft 365 includes over 40 ready-to-use templates that can help you meet a wide range of common regulatory and business policy needs. For example, there are DLP policy templates for:

- Gramm-Leach-Bliley Act (GLBA)
- Payment Card Industry Data Security Standard (PCI-DSS)
- United States Personally Identifiable Information (U.S. PII)
- United States Health Insurance Act (HIPAA)

You can fine tune a template by modifying any of the existing rules or adding new ones. For example, you can add new types of sensitive information to a rule, modify the counts in a rule to make it harder or easier to trigger, allow people to override the actions in a rule by providing a business justification, or change who notifications and incident reports are sent to. A DLP policy template is a flexible starting point for many common compliance scenarios.

You can also choose the Custom template, which has no default rules, and configure your DLP policy from scratch, to meet the specific compliance requirements for your organization.

Example: Identify sensitive information across all OneDrive for Business sites and restrict access for people outside your organization

OneDrive for Business accounts make it easy for people across your organization to collaborate and share documents. But a common concern for compliance officers is that sensitive information stored in OneDrive for Business accounts may be inadvertently shared with people outside your organization. A DLP policy can help mitigate this risk.

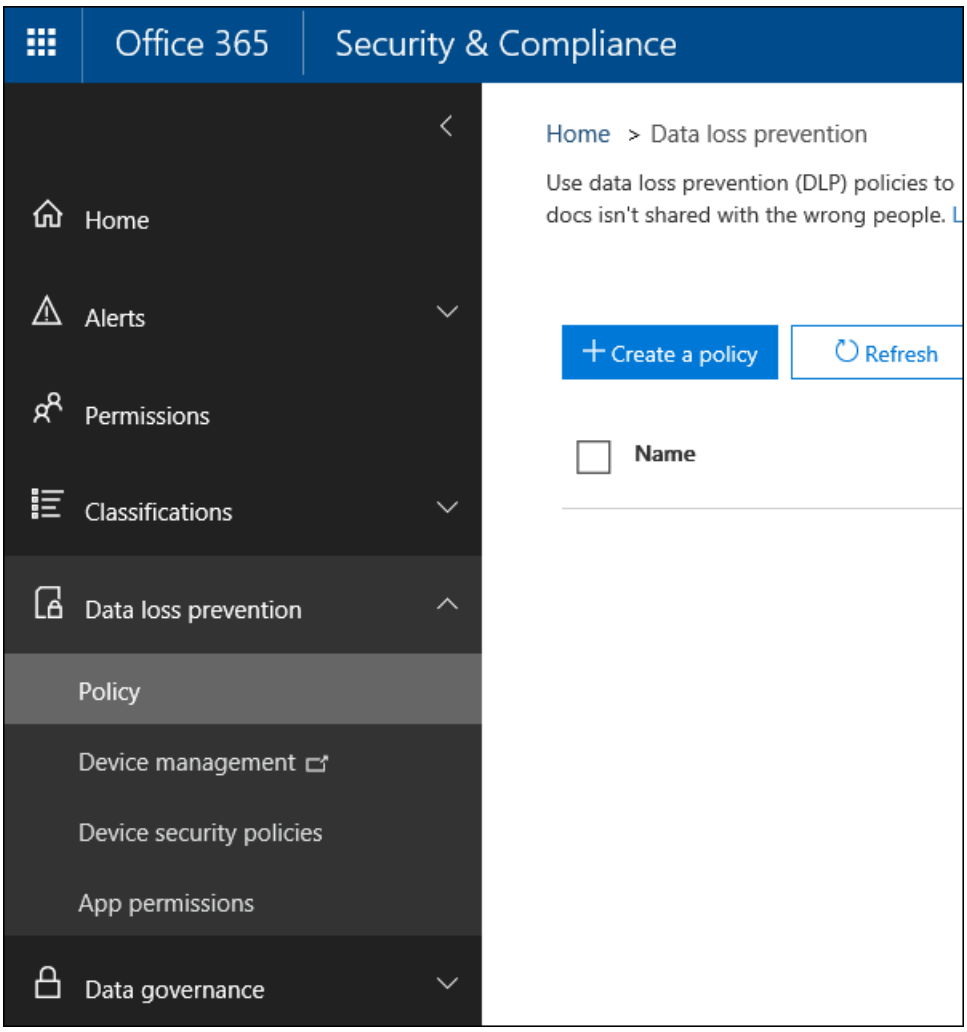
In this example, you'll create a DLP policy that identifies U.S. PII data, which includes Individual Taxpayer Identification Numbers (ITIN), Social Security Numbers, and U.S. passport numbers. You'll get started by using a template, and then you'll modify the template to meet your organization's compliance requirements—specifically, you'll:

- Add a couple of types of sensitive information—U.S. bank account numbers and U.S. driver's license numbers—so that the DLP policy protects even more of your sensitive data.
- Make the policy more sensitive, so that a single occurrence of sensitive information is enough to restrict access for external users.
- Allow users to override the actions by providing a business justification or reporting a false positive. This way, your DLP policy won't prevent people in your organization from getting their work done, provided they have a valid business reason for sharing the sensitive information.

Create a DLP policy from a template

1. Go to https://protection.office.com.
2. Sign in using your work or school account. You're now in the Security & Compliance Center.

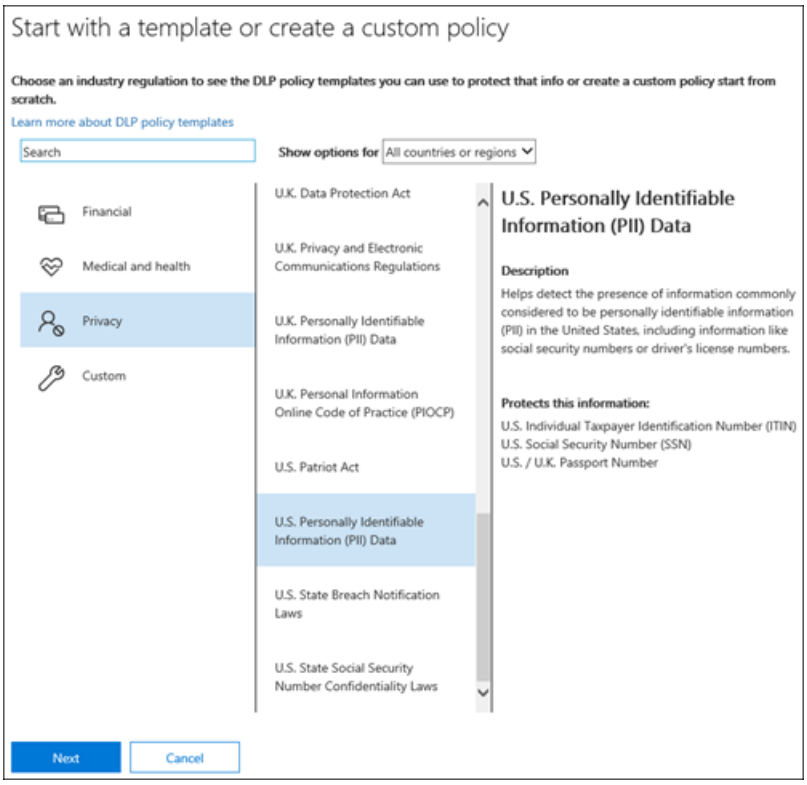
3. In the Security & Compliance Center > left navigation > **Data loss prevention** > **Policy** > **+ Create a policy**.



4. Choose the DLP policy template that protects the types of sensitive information that you need > **Next**.

   In this example, you'll select **Privacy** > **U.S. Personally Identifiable Information (PII) Data** because it already includes most of the types of sensitive information that you want to protect—you'll add a couple later.

   When you select a template, you can read the description on the right to learn what types of sensitive information the template protects.



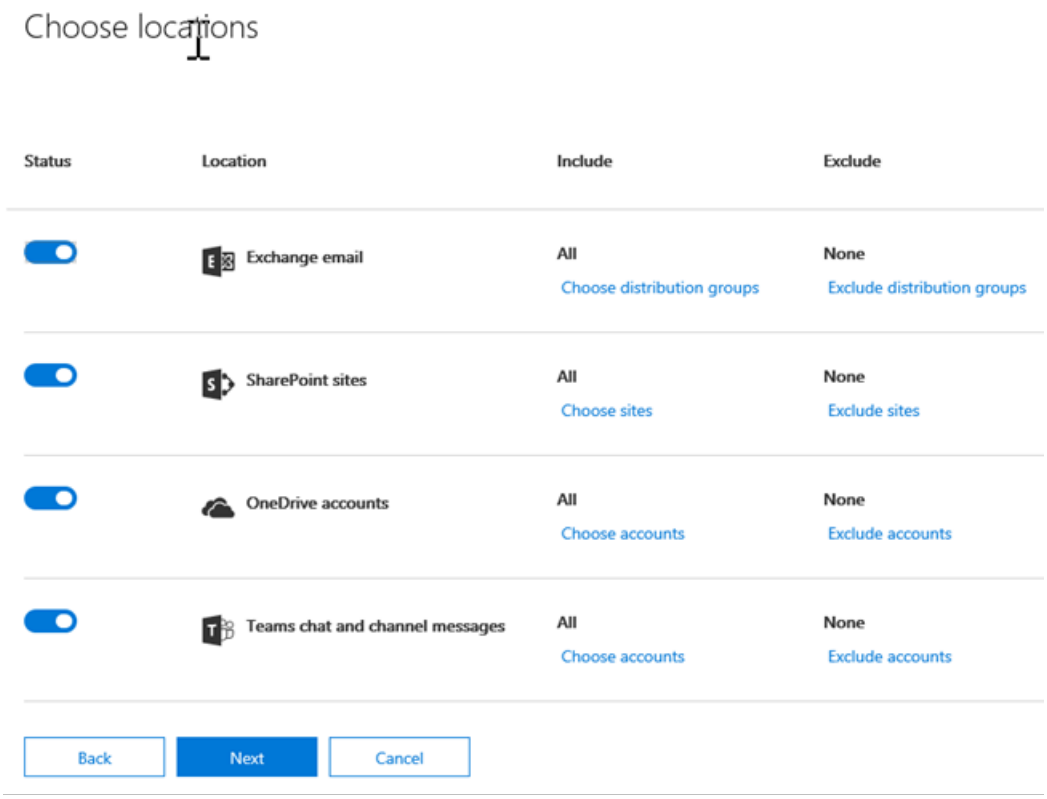
5. Name the policy > **Next**.

6. To choose the locations that you want the DLP policy to protect, do one of the following:

- Choose **All locations in Office 365** > **Next**.
- Choose **Let me choose specific locations** > **Next**. For this example, choose this.

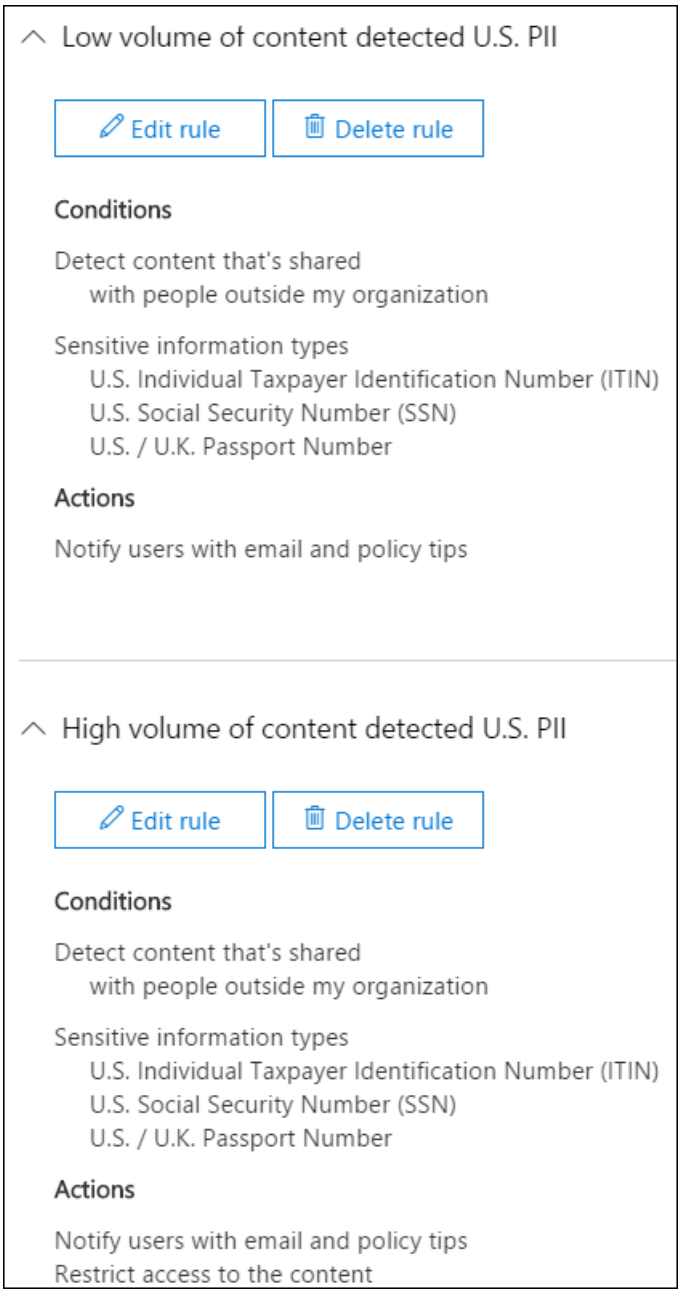
  To include or exclude an entire location such as all Exchange email or all OneDrive accounts, switch the **Status** of that location on or off.

  To include only specific SharePoint sites or OneDrive for Business accounts, switch the **Status** to on, and then click the links under **Include** to choose specific sites or accounts. When you apply a policy to a site, the rules configured in that policy are automatically applied to all subsites of that site.



In this example, to protect sensitive information stored in all OneDrive for Business accounts, turn off the **Status** for both **Exchange email** and **SharePoint sites**, and leave the **Status** on for **OneDrive accounts**.

7. Choose **Use advanced settings** > **Next**.
8. A DLP policy template contains predefined rules with conditions and actions that detect and act upon specific types of sensitive information. You can edit, delete, or turn off any of the existing rules, or add new ones. When done, click **Next**.

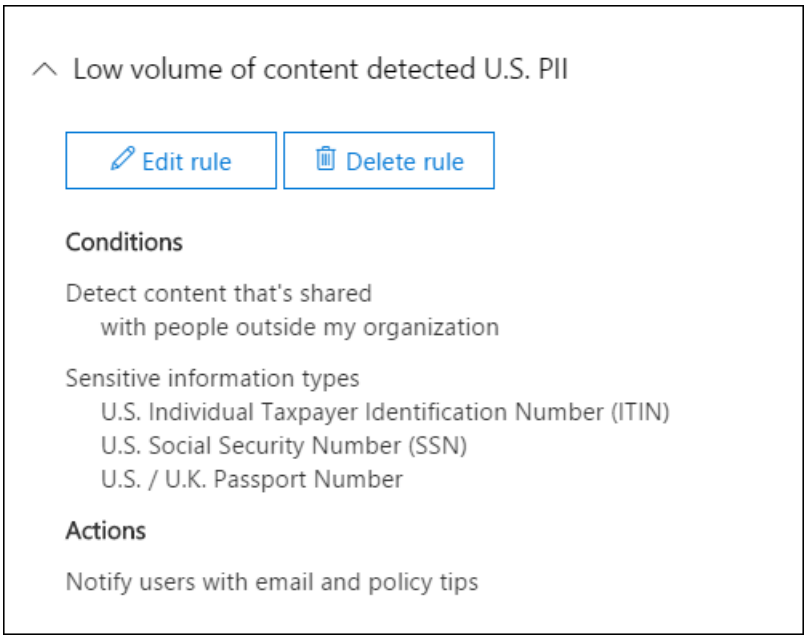


In this example, the U.S. PII Data template includes two predefined rules:

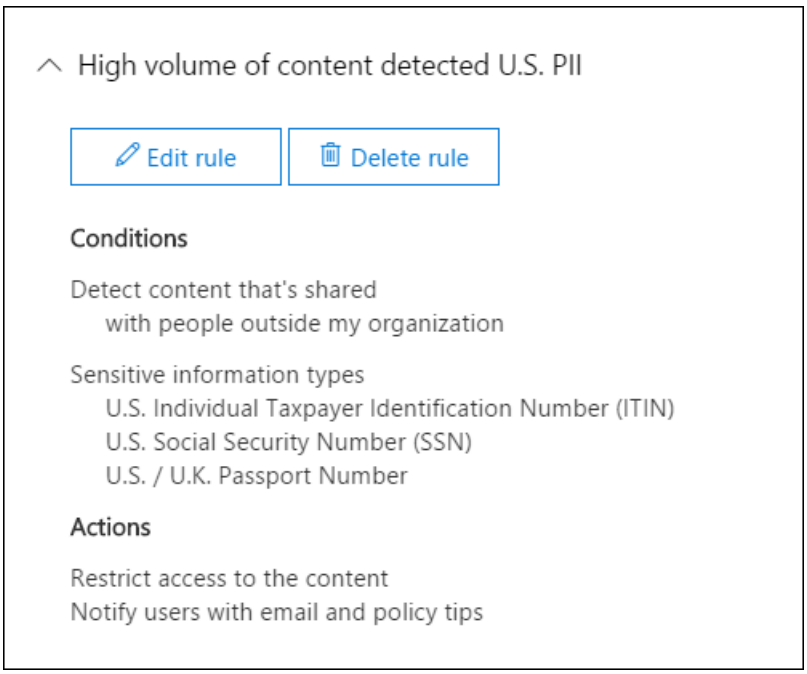
- **Low volume of content detected U.S. PII** This rule looks for files containing between 1 and 10 occurrences of each of three types of sensitive information (ITIN, SSN, and U.S. passport numbers), where the files are shared with people outside the organization. If found, the rule sends an email notification to the primary site collection administrator, document owner, and person who last modified the document.
- **High volume of content detected U.S. PII** This rule looks for files containing 10 or more occurrences of each of the same three sensitive information types, where the files are shared with people outside the organization. If found, this action also sends an email notification, plus it restricts access to the file. For content in a OneDrive for Business account, this means that permissions for the document are restricted for everyone except the primary site collection administrator, document owner, and person who last modified the document.

  To meet your organization's specific requirements, you may want to make the rules easier to trigger, so that a single occurrence of sensitive information is enough to block access for external users. After looking at these rules, you understand that you don't need low and high count rules—you need only a single rule that blocks access if any occurrence of sensitive information is found.

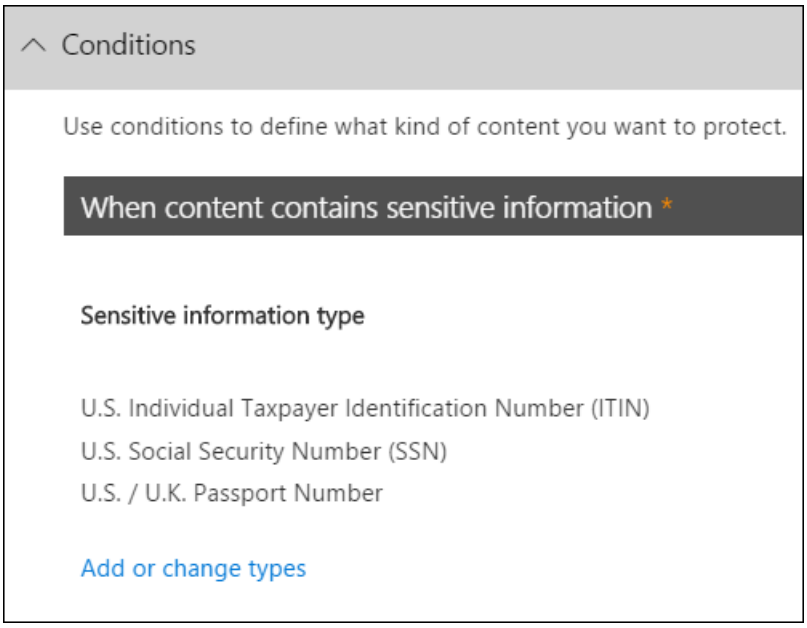
  So you expand the rule named **Low volume of content detected U.S. PII** > **Delete rule**.

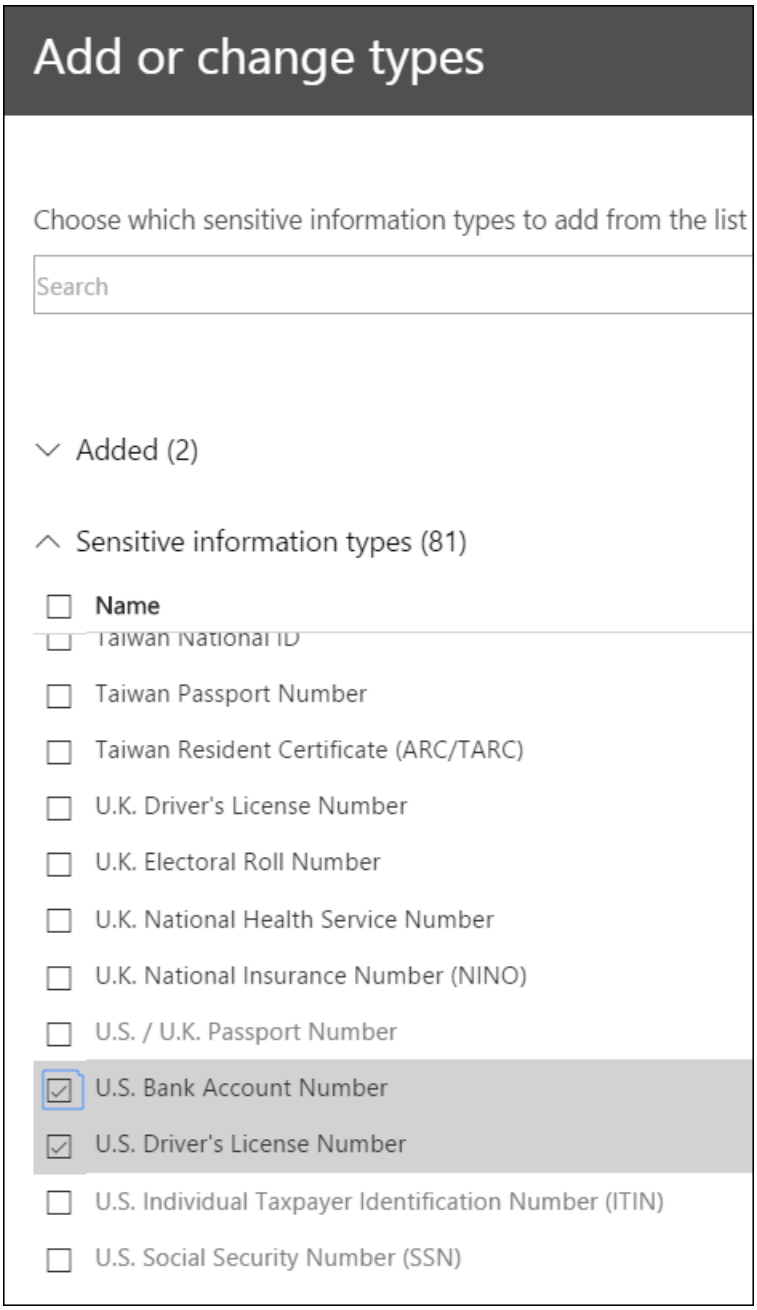


9. Now, in this example, you need to add two sensitive information types (U.S. bank account numbers and U.S. driver's license numbers), allow people to override a rule, and change the count to any occurrence. You can do all of this by editing one rule, so select **High volume of content detected U.S. PII** > **Edit rule**.



10. To add a sensitive information type, in the **Conditions** section > **Add or change types**. Then, under **Add or change types** > choose **Add** > select **U.S. Bank Account Number** and **U.S. Driver's License Number** > **Add** > **Done**.

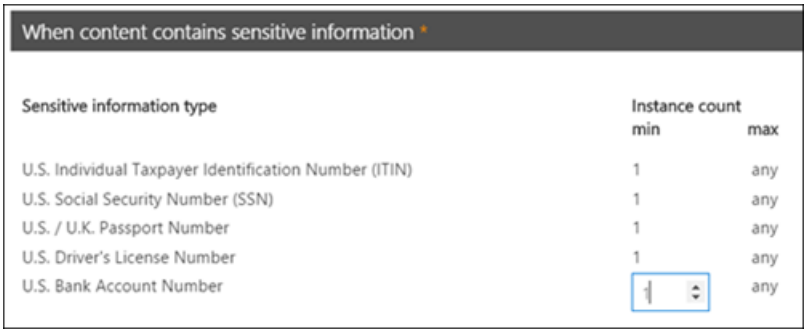




11. To change the count (the number of instances of sensitive information required to trigger the rule), under **Instance count** > choose the **min** value for each type > enter 1. The minimum count cannot be empty.

The maximum count can be empty; an empty **max** value convert to **any**.

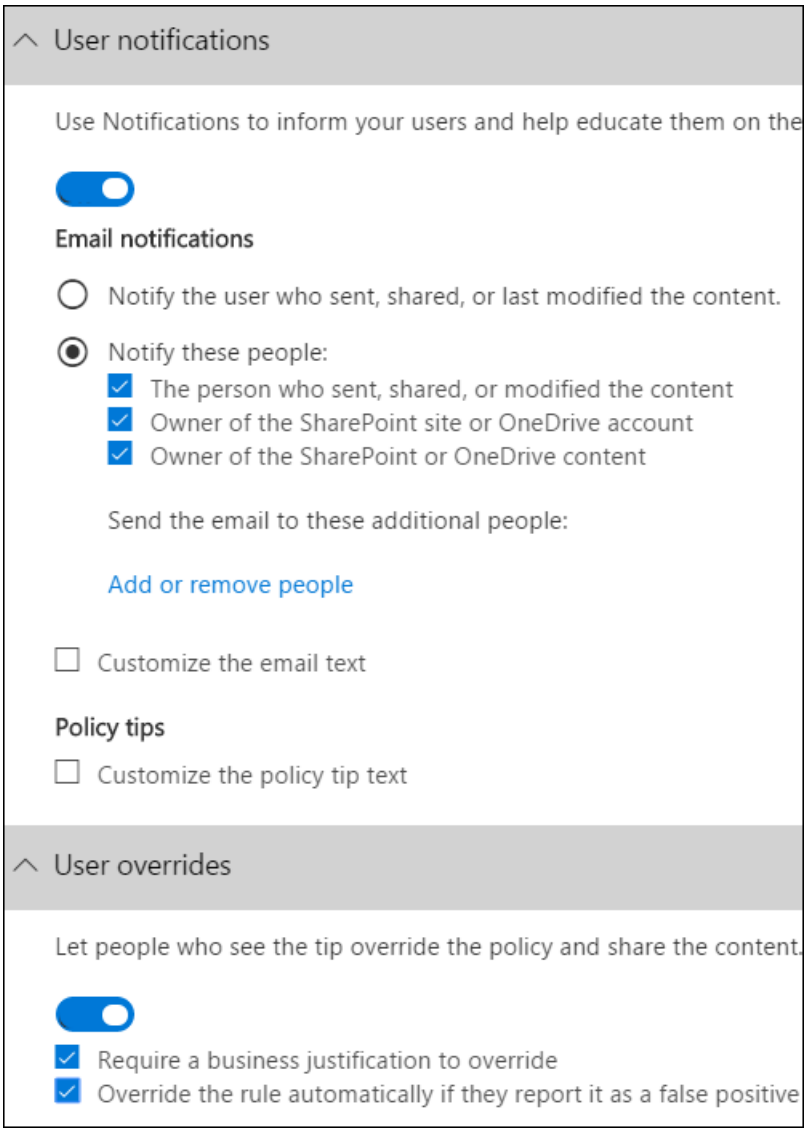
When finished, the min count for all of the sensitive information types should be **1** and the max count should be **any**. In other words, any occurrence of this type of sensitive information will satisfy this condition.



12. For the final customization, you don't want your DLP policies to block people from doing their work when they have a valid business justification or encounter a false positive, so you want the user notification to include options to override the blocking action.

    In the **User notifications** section, you can see that email notifications and policy tips are turned on by default for this rule in the template.

    In the **User overrides** section, you can see that overrides for a business justification are turned on, but overrides to report false positives are not. Choose **Override the rule automatically if they report it as a false positive**.



13. At the top of the rule editor, change the name of this rule from the default **High volume of content detected U.S. PII** to **Any content detected with U.S. PII** because it's now triggered by any occurrence of its sensitive information types.

14. At the bottom of the rule editor > **Save**.

15. Review the conditions and actions for this rule > **Next**.

    On the right, notice the **Status** switch for the rule. If you turn off an entire policy, all rules contained in the policy are also turned off. However, here you can turn off a specific rule without turning off the entire policy. This can be useful when you need to investigate a rule that is generating a large number of false positives.

16. On the next page, read and understand the following, and then choose whether to turn on the rule or test it out first > **Next**.

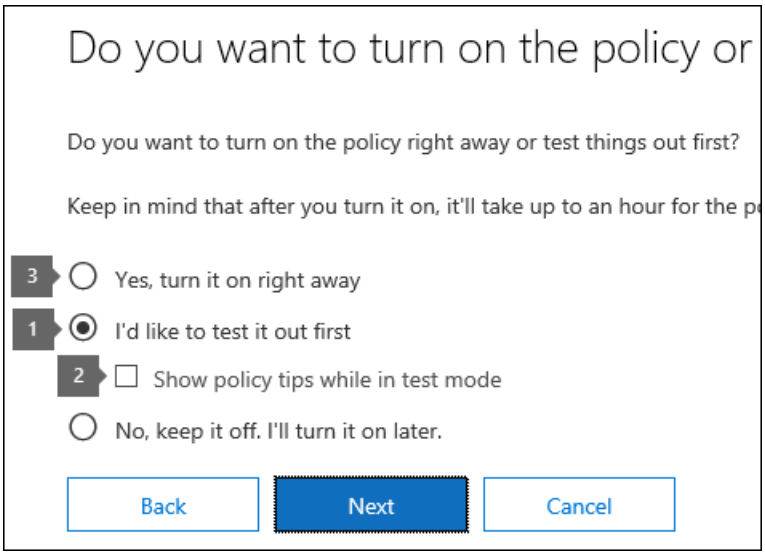
    Before you create your DLP policies, you should consider rolling them out gradually to assess their impact and test their effectiveness before you fully enforce them. For example, you don't want a new DLP policy to unintentionally block access to thousands of documents that people require to get their work done.

    If you're creating DLP policies with a large potential impact, we recommend following this sequence:

17. Start in test mode without Policy Tips and then use the DLP reports to assess the impact. You can use DLP reports to view the number, location, type, and severity of policy matches. Based on the results, you can fine tune the rules as needed. In test mode, DLP policies will not impact the productivity of people working in your organization.

18. Move to Test mode with notifications and Policy Tips so that you can begin to teach users about your compliance policies and prepare them for the rules that are going to be applied. At this stage, you can also ask users to report false positives so that you can further refine the rules.

19. Turn on the policies so that the rules are enforced and the content's protected. Continue to monitor the DLP reports and any incident reports or notifications to make sure that the results are what you intend.



20. Review your settings for this policy > choose **Create**.

After you create and turn on a DLP policy, it's deployed to any content sources that it includes, such as SharePoint Online sites or OneDrive for Business accounts, where the policy begins automatically enforcing its rules on that content.

View the status of a DLP policy

At any time, you can view the status of your DLP policies on the **Policy** page in the **Data loss prevention** section of the Security & Compliance Center. Here you can find important information, such as whether a policy was successfully enabled or disabled, or whether the policy is in test mode.

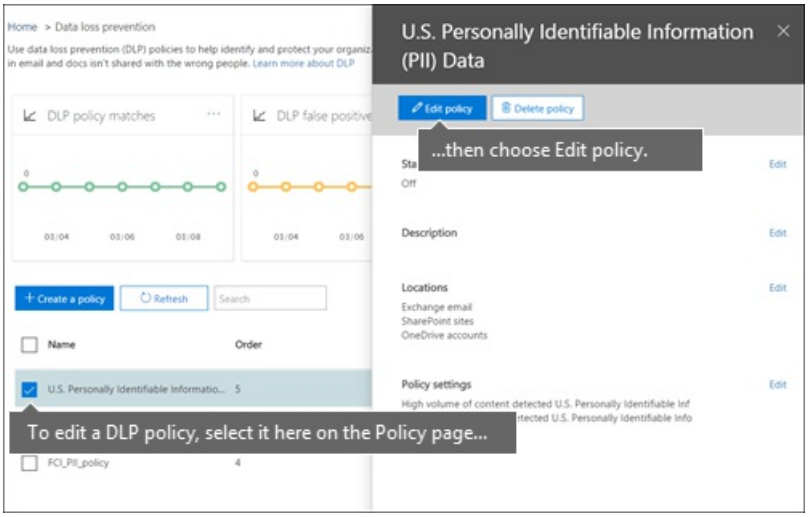
Here are the different statuses and what they mean.

STATUS	EXPLANATION
Turning on...	The policy is being deployed to the content sources that it includes. The policy is not yet enforced on all sources.
Testing, with notifications	The policy is in test mode. The actions in a rule are not applied, but policy matches are collected and can be viewed by using the DLP reports. Notifications about policy matches are sent to the specified recipients.
Testing, without notifications	The policy is in test mode. The actions in a rule are not applied, but policy matches are collected and can be viewed by using the DLP reports. Notifications about policy matches are not sent to the specified recipients.
On	The policy is active and enforced. The policy was successfully deployed to all its content sources.
Turning off...	The policy is being removed from the content sources that it includes. The policy may still be active and enforced on some sources. Turning off a policy may take up to 45 minutes.
Off	The policy is not active and not enforced. The settings for the policy (sources, keywords, duration, etc) are saved.
Deleting...	The policy is in the process of being deleted. The policy is not active and not enforced. It normally takes an hour for a policy to delet

Turn off a DLP policy

You can edit or turn off a DLP policy at any time. Turning off a policy disables all of the rules in the policy.

To edit or turn off a DLP policy, on the **Policy** page > select the policy > **Edit policy**.



In addition, you can turn off each rule individually by editing the policy and then toggling off the **Status** of that rule, as described above.

Create, test, and tune a DLP policy

2/18/2021 • 12 minutes to read • Edit Online

Data loss prevention (DLP) helps you prevent the unintentional or accidental sharing of sensitive information.

DLP examines email messages and files for sensitive information, like a credit card number. Using DLP you can detect sensitive information, and take action such as:

- Log the event for auditing purposes
- Display a warning to the end user who is sending the email or sharing the file
- Actively block the email or file sharing from taking place

Permissions

Members of your compliance team who will create DLP policies need permissions to the Compliance Center. By default, your tenant admin will have access can give compliance officers and other people access. Follow these steps:

1. Create a group in Microsoft 365 and add compliance officers to it.
2. Create a role group on the **Permissions** page of the Security & Compliance Center.
3. While creating the role group, use the **Choose Roles** section to add the following role to the role group: **DLP Compliance Management**.
4. Use the **Choose Members** section to add the Microsoft 365 group you created before to the role group.

Use the **View-Only DLP Compliance Management** role to create role group with view-only privileges to the DLP policies and DLP reports.

For more information, see Give users access to the Office 365 Compliance Center.

These permissions are required to create and apply a DLP policy not to enforce policies.

How sensitive information is detected by DLP

DLP finds sensitive information by regular expression (RegEx) pattern matching, in combination with other indicators such as the proximity of certain keywords to the matching patterns. For example, a VISA credit card number has 16 digits. But, those digits can be written in different ways, such as 1111-1111-1111-1111, 1111 1111 1111 1111, or 1111111111111111.

Any 16-digit string is not necessarily a credit card number, it could be a ticket number from a help desk system, or a serial number of a piece of hardware. To tell the difference between a credit card number and a harmless 16-digit string, a calculation is performed (checksum) to confirm that the numbers match a known pattern from the various credit card brands.

If DLP finds keywords such as "VISA" or "AMEX", near date values that might be the credit card expiry date, DLP also uses that data to help it decide whether the string is a credit card number or not.

In other words, DLP is smart enough to recognize the difference between these two strings of text in an email:

- "Can you order me a new laptop. Use my VISA number 1111-1111-1111-1111, expiry 11/22, and send me the estimated delivery date when you have it."
- "My laptop serial number is 2222-2222-2222-2222 and it was purchased on 11/2010. By the way, is my

travel visa approved yet?"

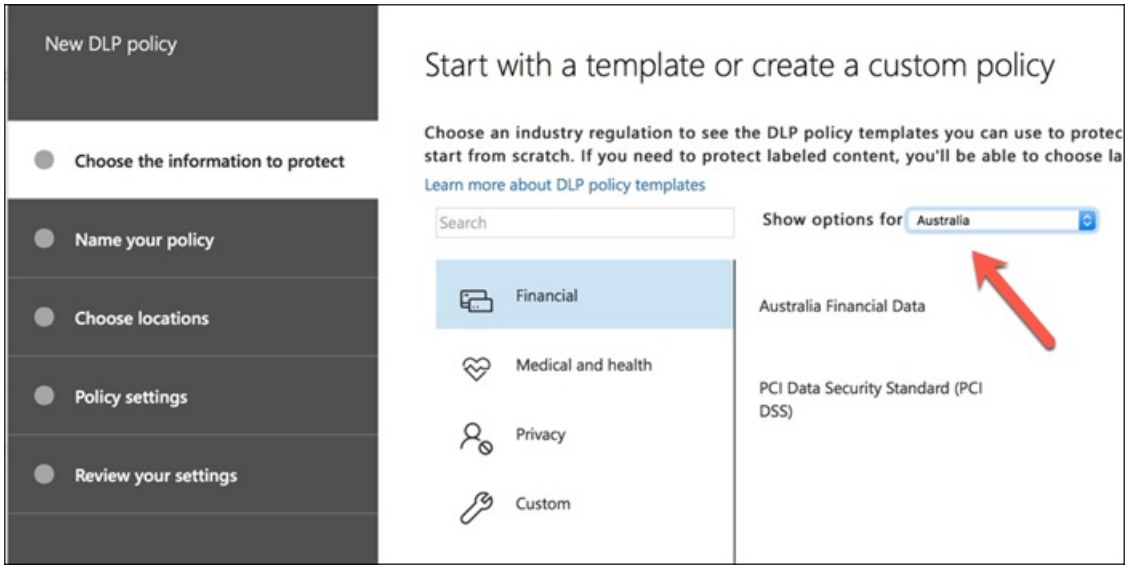
See Sensitive information type entity definitions that explains how each information type is detected.

Where to start with data loss prevention

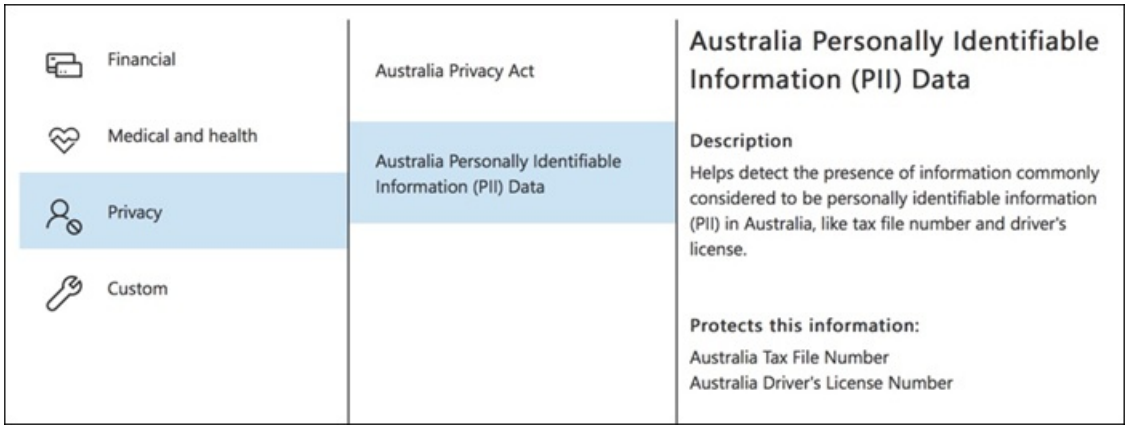
When the risks of data leakage aren't entirely obvious, it's difficult to work out where exactly you should start with implementing DLP. Fortunately, DLP policies can be run in "test mode", allowing you to gauge their effectiveness and accuracy before you turn them on.

DLP policies for Exchange Online can be managed through the Exchange admin center. But you can configure DLP policies for all workloads through the Security & Compliance Center, so that's what I'll use for demonstrations in this article. In the Security & Compliance Center, you'll find the DLP policies under **Data loss prevention** > **Policy**. Choose **Create a policy** to start.

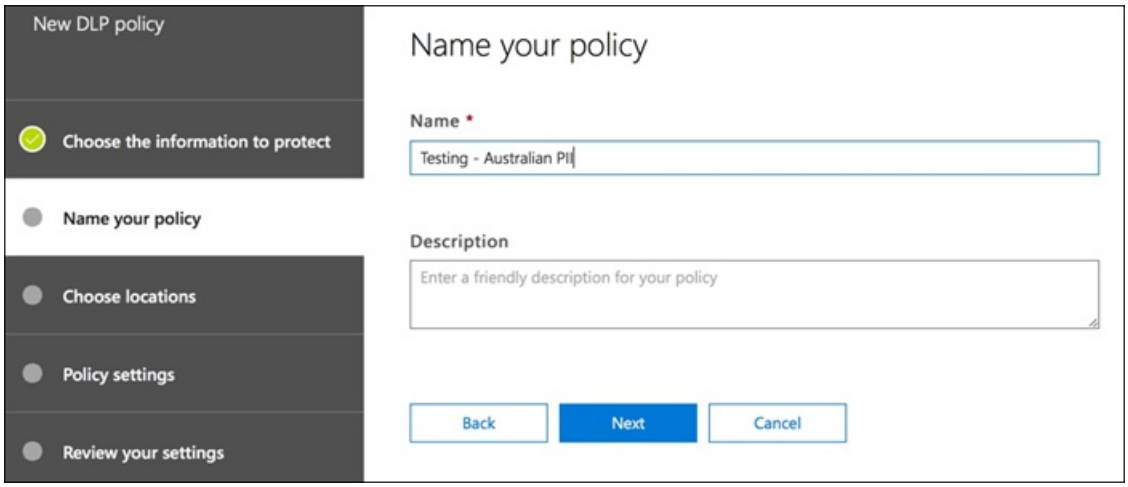
Microsoft 365 provides a range of DLP policy templates you can use to create policies. Let's say that you're an Australian business. You can filter the templates on Australia, and choose Financial, Medical and Health, and Privacy.



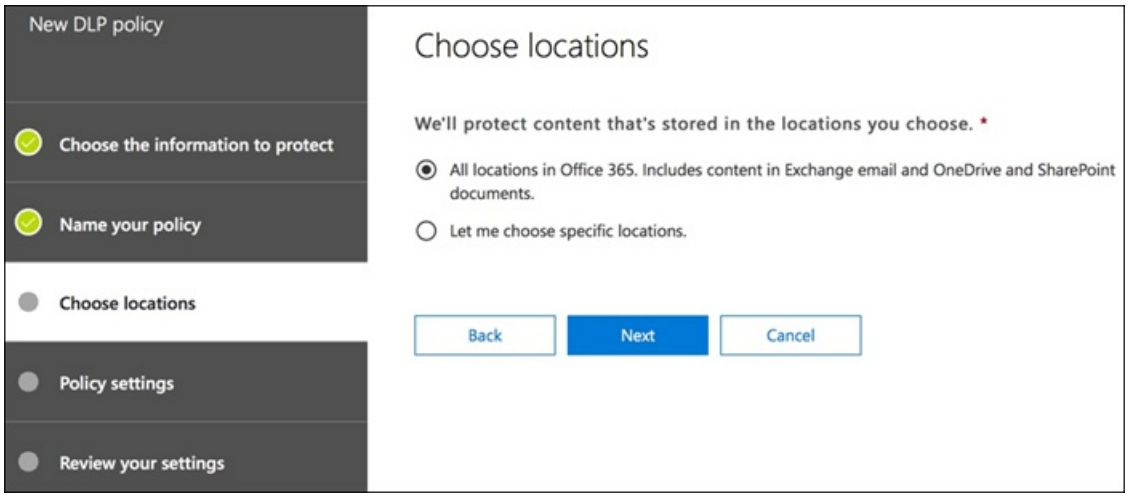
For this demonstration I'll choose Australian Personally Identifiable Information (PII) Data, which includes the information types of Australian Tax File Number (TFN) and Driver's License Number.



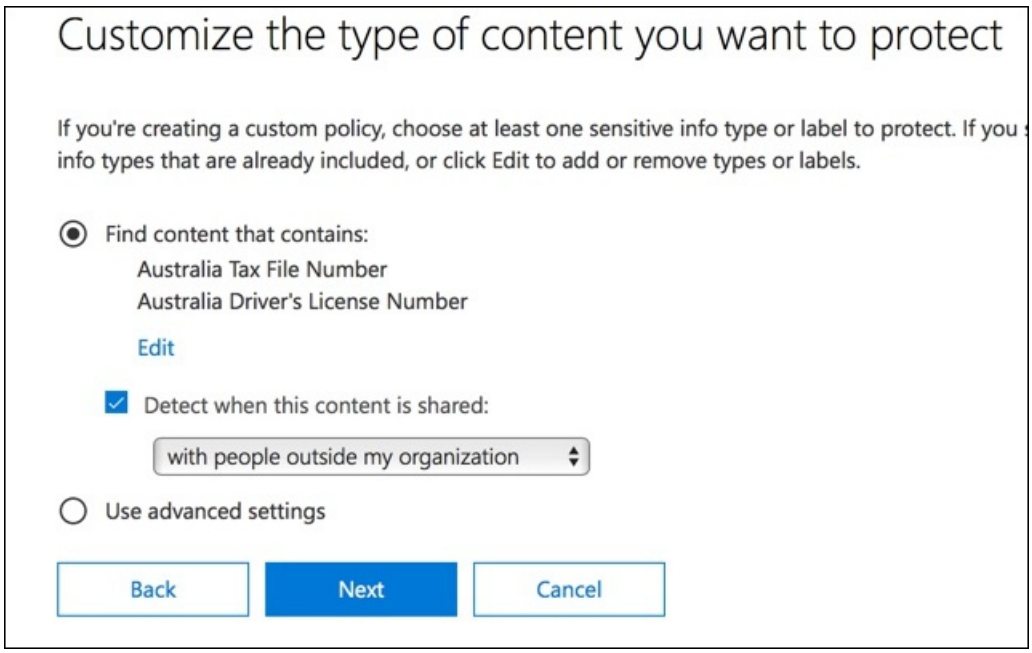
Give your new DLP policy a name. The default name will match the DLP policy template, but you should choose a more descriptive name of your own, because multiple policies can be created from the same template.



Choose the locations that the policy will apply to. DLP policies can apply to Exchange Online, SharePoint Online, and OneDrive for Business. I am going to leave this policy configured to apply to all locations.



At the first **Policy Settings** step, just accept the defaults for now. You can customize DLP policies, but the defaults are a fine place to start.

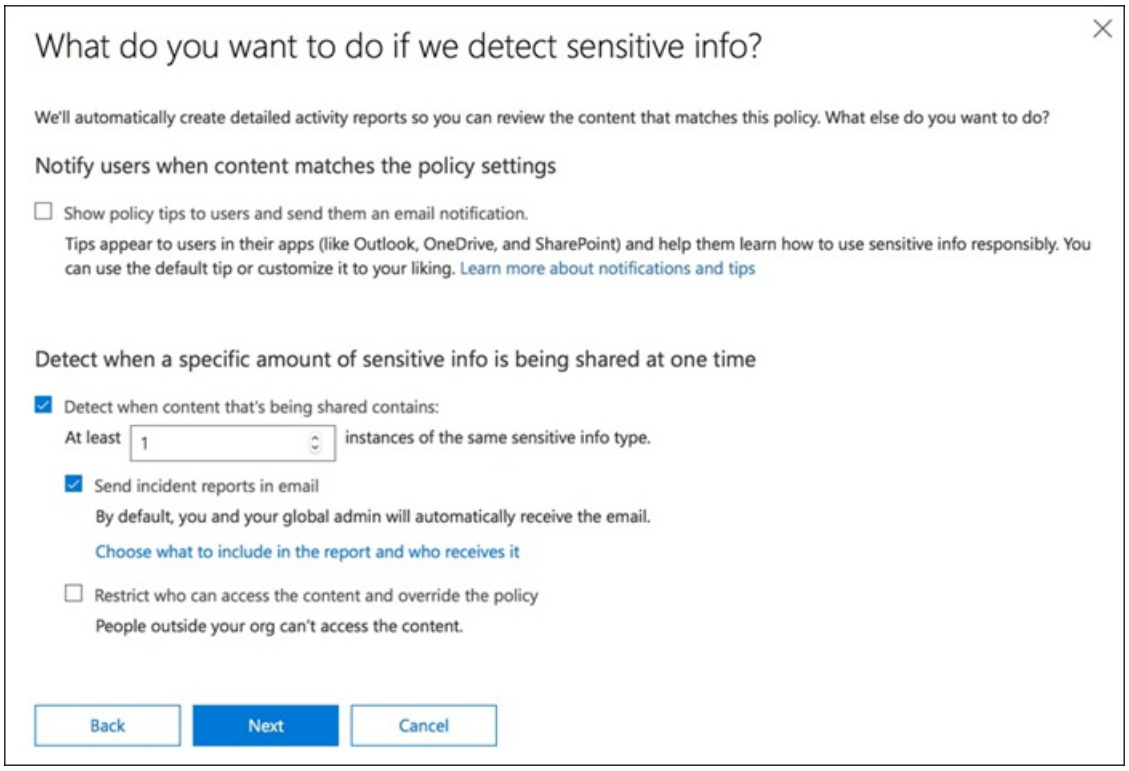


After clicking Next,** you'll be presented with an additional **Policy Settings** page with more customization options. For a policy that you are just testing, here's where you can start to make some adjustments.

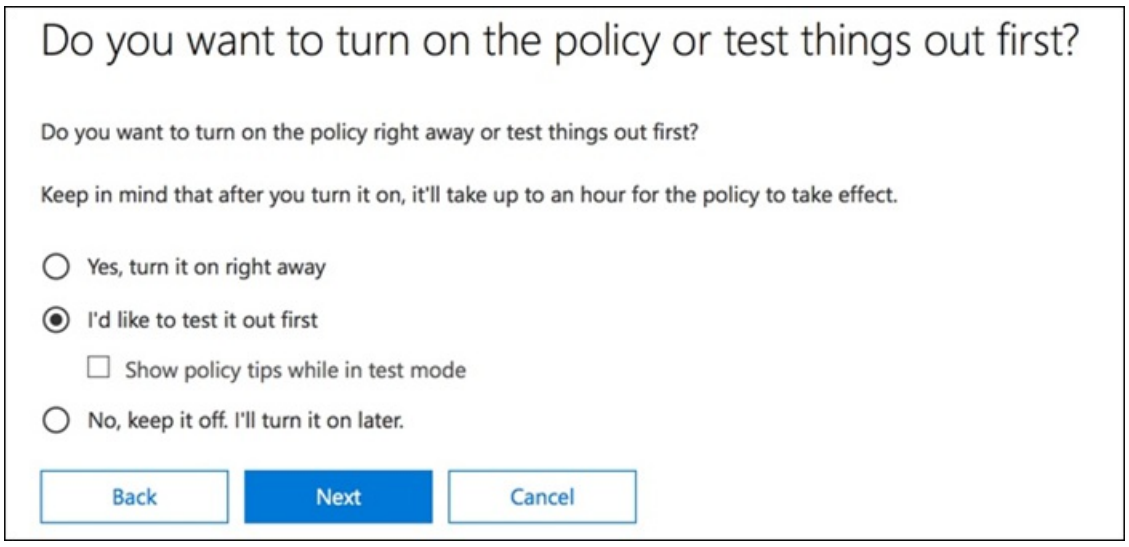
- I've turned off policy tips for now, which is a reasonable step to take if you're just testing things out and don't want to display anything to users yet. Policy tips display warnings to users that they're about to violate a DLP

policy. For example, an Outlook user will see a warning that the file they've attached contains credit card numbers and will cause their email to be rejected. The goal of policy tips is to stop the non-compliant behaviour before it happens.

- I've also decreased the number of instances from 10 to 1, so that this policy will detect any sharing of Australian PII data, not just bulk sharing of the data.
- I've also added another recipient to the incident report email.



Finally, I've configured this policy to run in test mode initially. Notice there's also an option here to disable policy tips while in test mode. This gives you the flexibility to have policy tips enabled in the policy, but then decide whether to show or suppress them during your testing.



On the final review screen click **Create** to finish creating the policy.

Test a DLP policy

Your new DLP policy will begin to take effect within about 1 hour. You can sit and wait for it to be triggered by normal user activity, or you can try to trigger it yourself. Earlier I linked to Sensitive information type entity definitions, which provides you with information about how to trigger DLP matches.

As an example, the DLP policy I created for this article will detect Australian tax file numbers (TFN). According to the documentation, the match is based on the following criteria.

Australia Tax File Number

Format: 8-9 digits

Pattern: 8-9 digits typically presented with spaces as follows:

- Three digits
- An optional space
- Three digits
- An optional space
- 2-3 digits where the last digit is a check digit

Checksum: Yes

Definition:

A DLP policy is 95% confident that it's detected this type of sensitive information if, within a proximity of 300 characters:

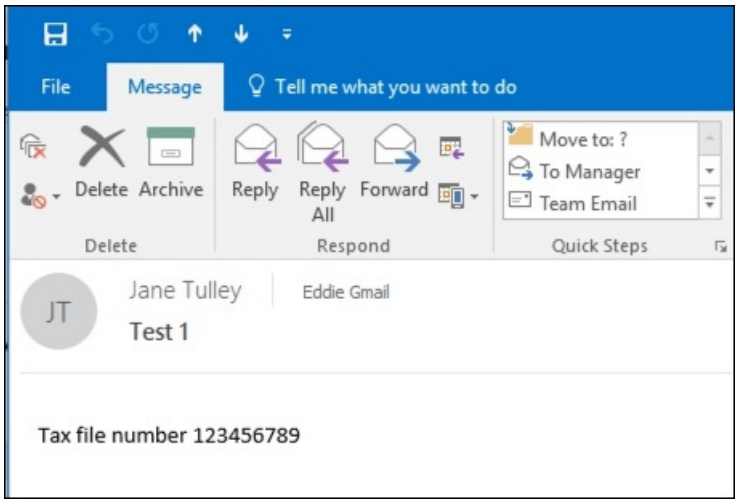
- The function `Func_australian_tax_file_number` finds content that matches the pattern.
- A keyword from `Keyword_Australia_Tax_File_Number` is found.
- No keyword from `Keyword_number_exclusions` is found.
- The checksum passes.

A DLP policy is 85% confident that it's detected this type of sensitive information if, within a proximity of 300 characters:

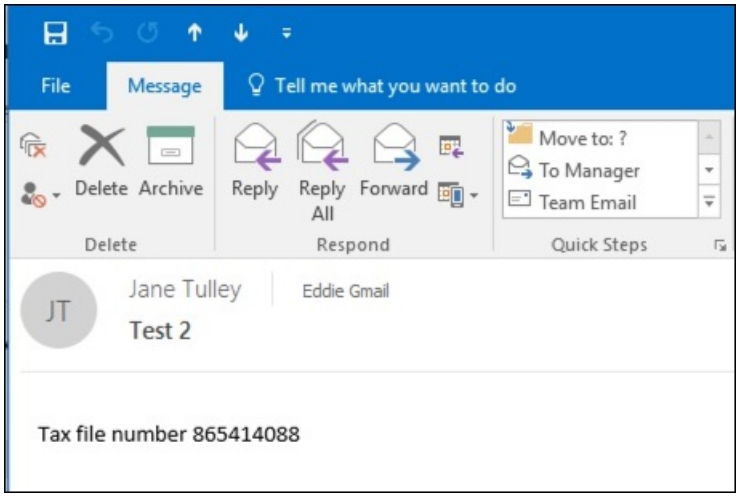
- The function `Func_australian_tax_file_number` finds content that matches the pattern.
- No keyword from `Keyword_Australia_Tax_File_Number` or `Keyword_number_exclusions` is found.
- The checksum passes.

```
<!-- Australia Tax File Number -->
<Entity id="e29bc95f-ff70-4a37-aa01-04d17360a4c5" patternsProximity="300" recommendedConfidence="85">
    <Pattern confidenceLevel="95">
        <IdMatch idRef="Func_australian_tax_file_number" />
        <Any minMatches="1">
          <Match idRef="Keyword_Australia_Tax_File_Number" />
        </Any>
        <Any minMatches="0" maxMatches="0">
          <Match idRef="Keyword_number_exclusions" />
        </Any>
  </Pattern>
```

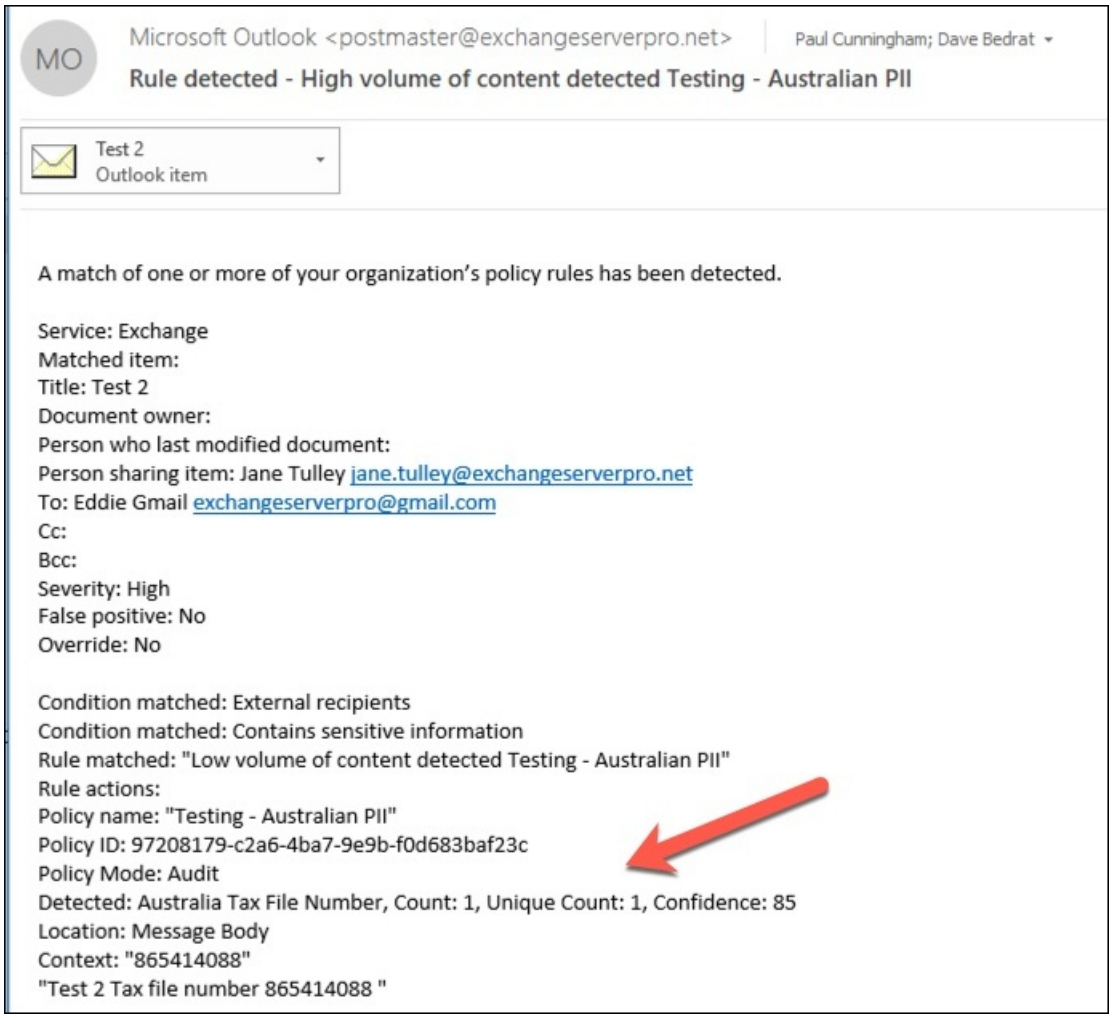
To demonstrate TFN detection in a rather blunt manner, an email with the words "Tax file number" and a 9 digit string in close proximity will sail through without any issues. The reason it does not trigger the DLP policy is that the 9-digit string must pass the checksum that indicates it is a valid TFN and not just a harmless string of numbers.



In comparison, an email with the words "Tax file number" and a valid TFN that passes the checksum will trigger the policy. For the record here, the TFN I'm using was taken from a website that generates valid, but not genuine, TFNs. Such sites are very useful because one of the most common mistakes when testing a DLP policy is using a fake number that's not valid and won't pass the checksum (and therefore won't trigger the policy).



The incident report email includes the type of sensitive information that was detected, how many instances were detected, and the confidence level of the detection.

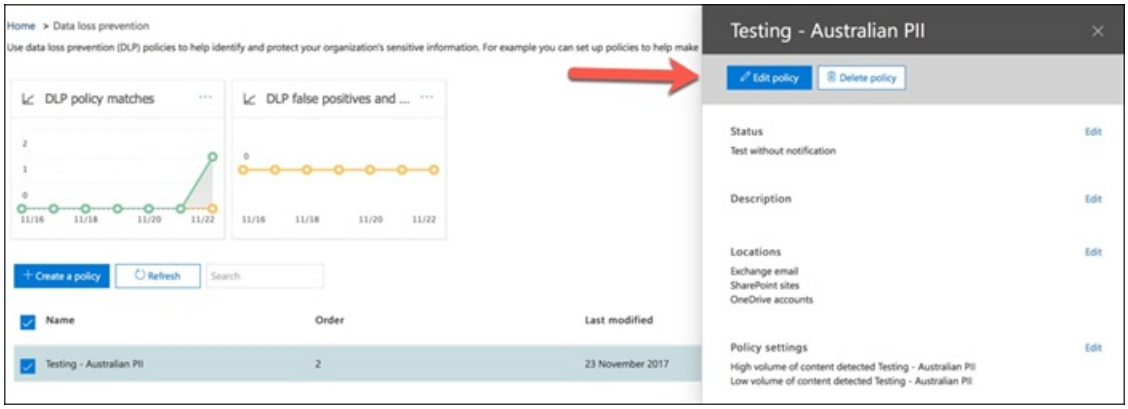


If you leave your DLP policy in test mode and analyze the incident report emails, you can start to get a feel for the accuracy of the DLP policy and how effective it will be when it is enforced. In addition to the incident reports, you can use the DLP reports to see an aggregated view of policy matches across your tenant.

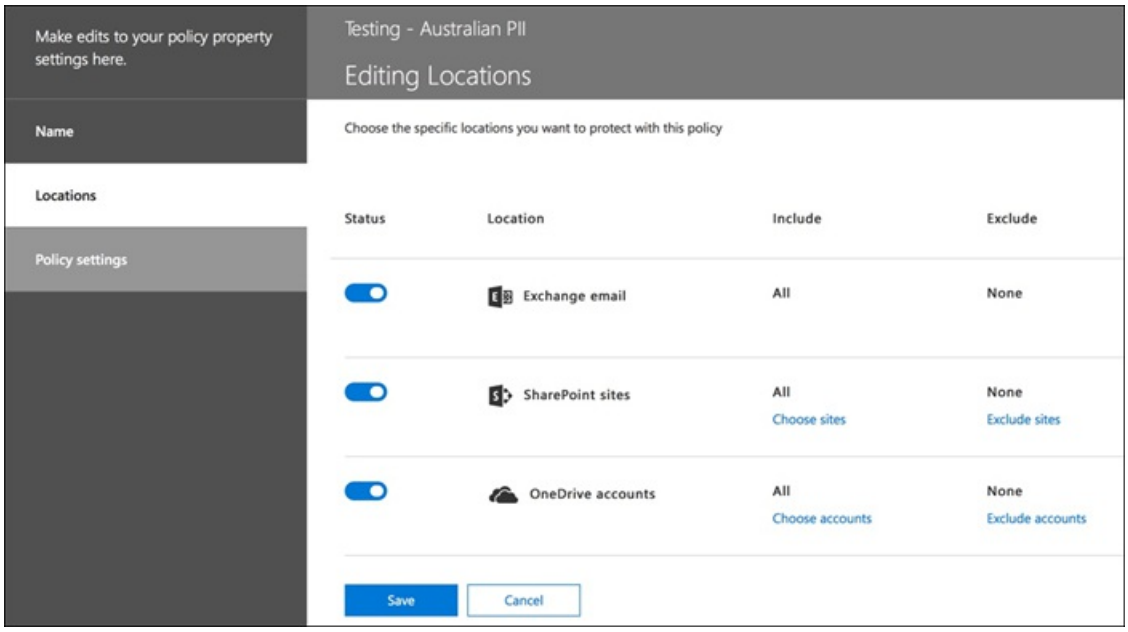
Tune a DLP policy

As you analyze your policy hits you might want to make some adjustments to how the policies behave. As a simple example, you might determine that one TFN in email is not a problem (I think it still is, but let's go with it for the sake of demonstration), but two or more instances is a problem. Multiple instances could be a risky scenario such as an employee emailing a CSV export from the HR database to an external party, for example an external accounting service. Definitely something you would prefer to detect and block.

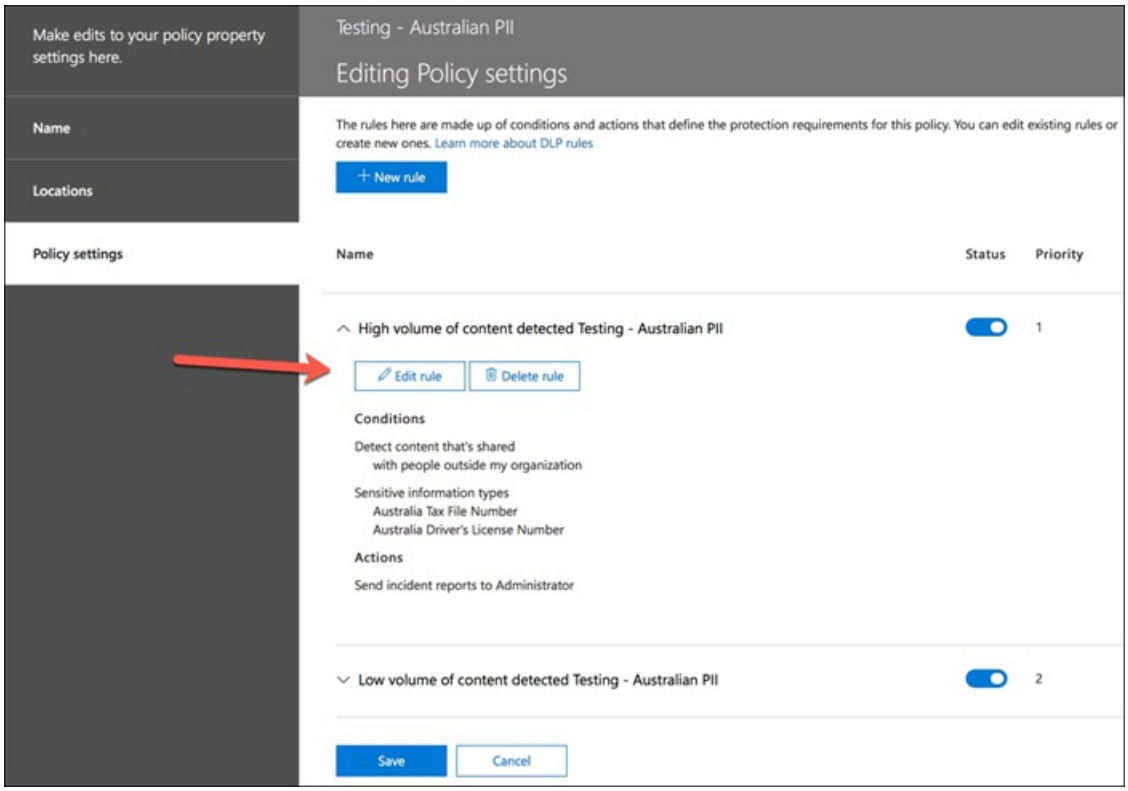
In the Security & Compliance Center you can edit an existing policy to adjust the behaviour.



You can adjust the location settings so that the policy is applied only to specific workloads, or to specific sites and accounts.

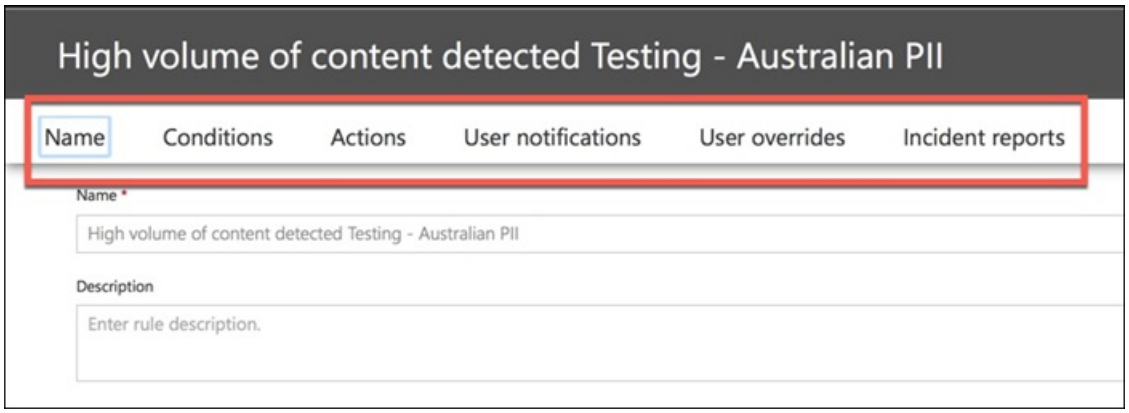


You can also adjust the policy settings and edit the rules to better suit your needs.

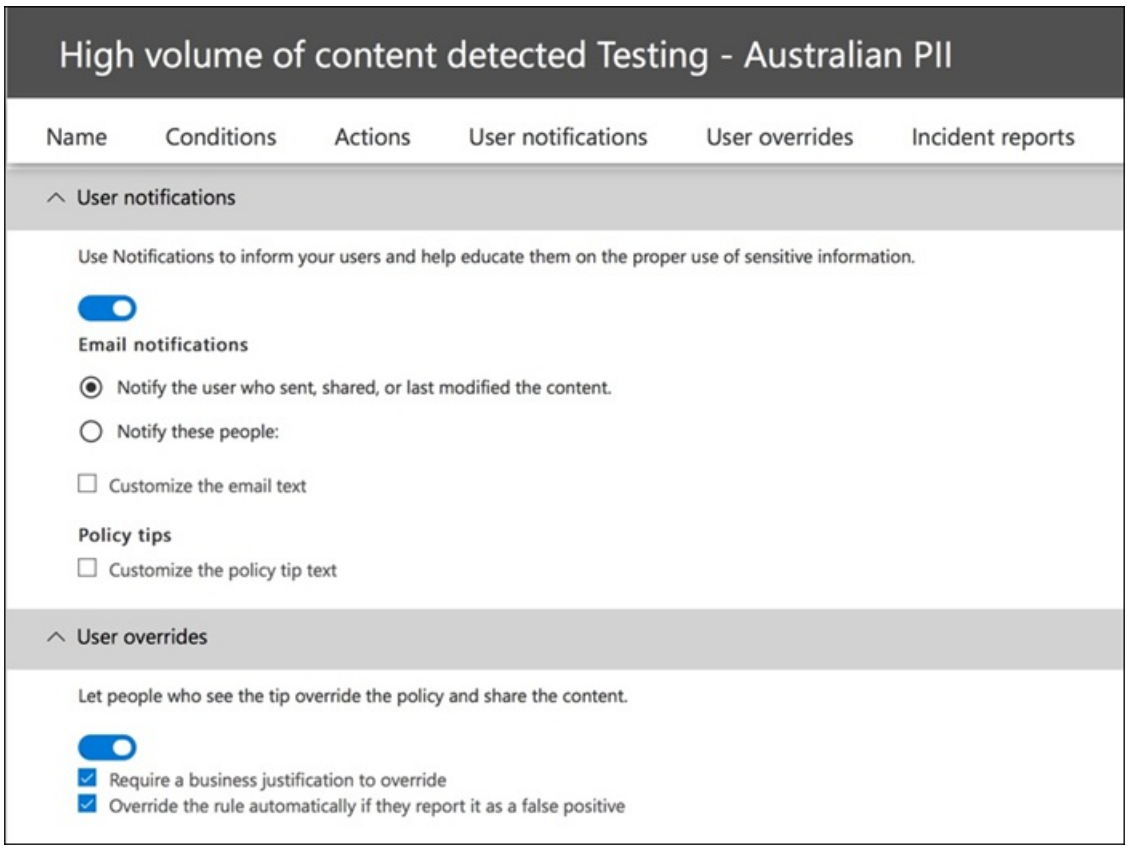


When editing a rule within a DLP policy you can change:

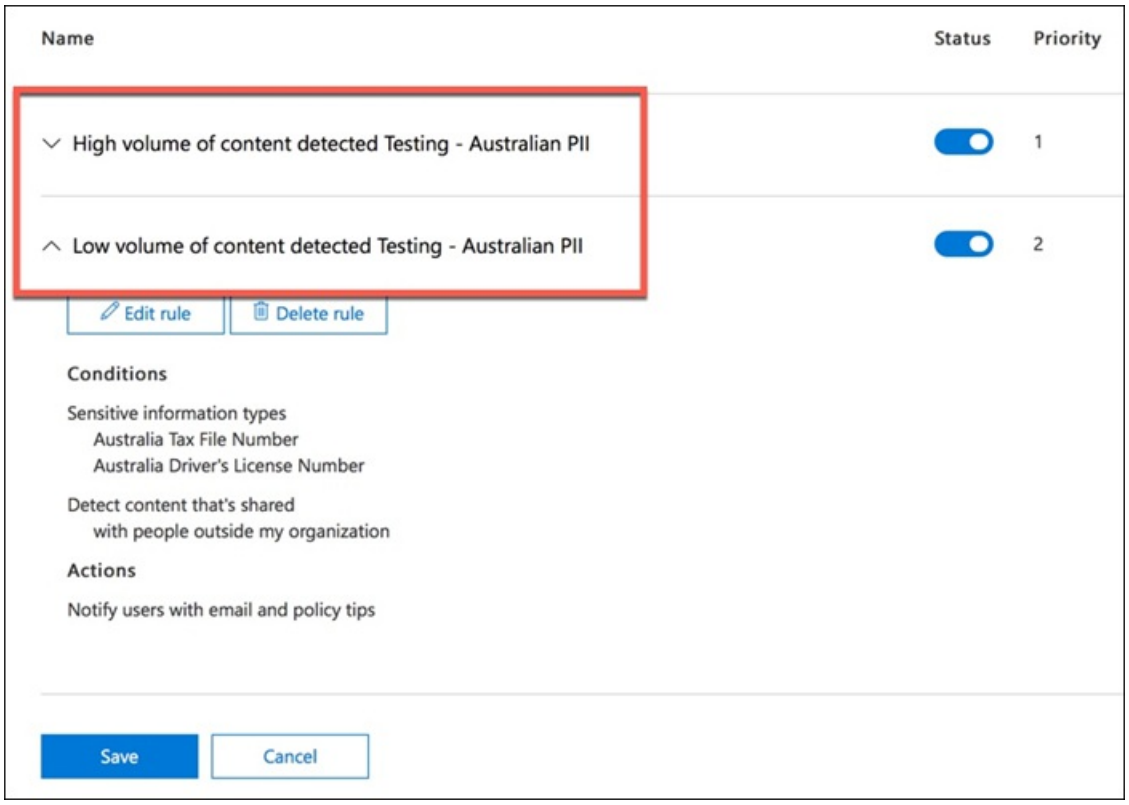
- The conditions, including the type and number of instances of sensitive data that will trigger the rule.
- The actions that are taken, such as restricting access to the content.
- User notifications, which are policy tips that are displayed to the user in their email client or web browser.
- User overrides, which determines whether users can choose to proceed with their email or file sharing anyway.
- Incident reports, to notify administrators.



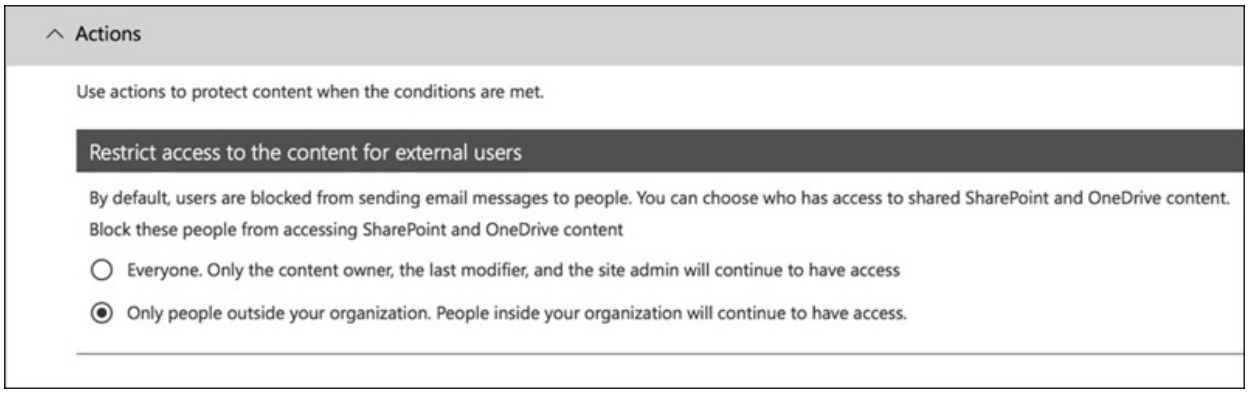
For this demonstration I've added user notifications to the policy (be careful of doing this without adequate user awareness training), and allowed users to override the policy with a business justification or by flagging it as a false positive. Note that you can also customize the email and policy tip text if you want to include any additional information about your organization's policies, or prompt users to contact support if they have questions.



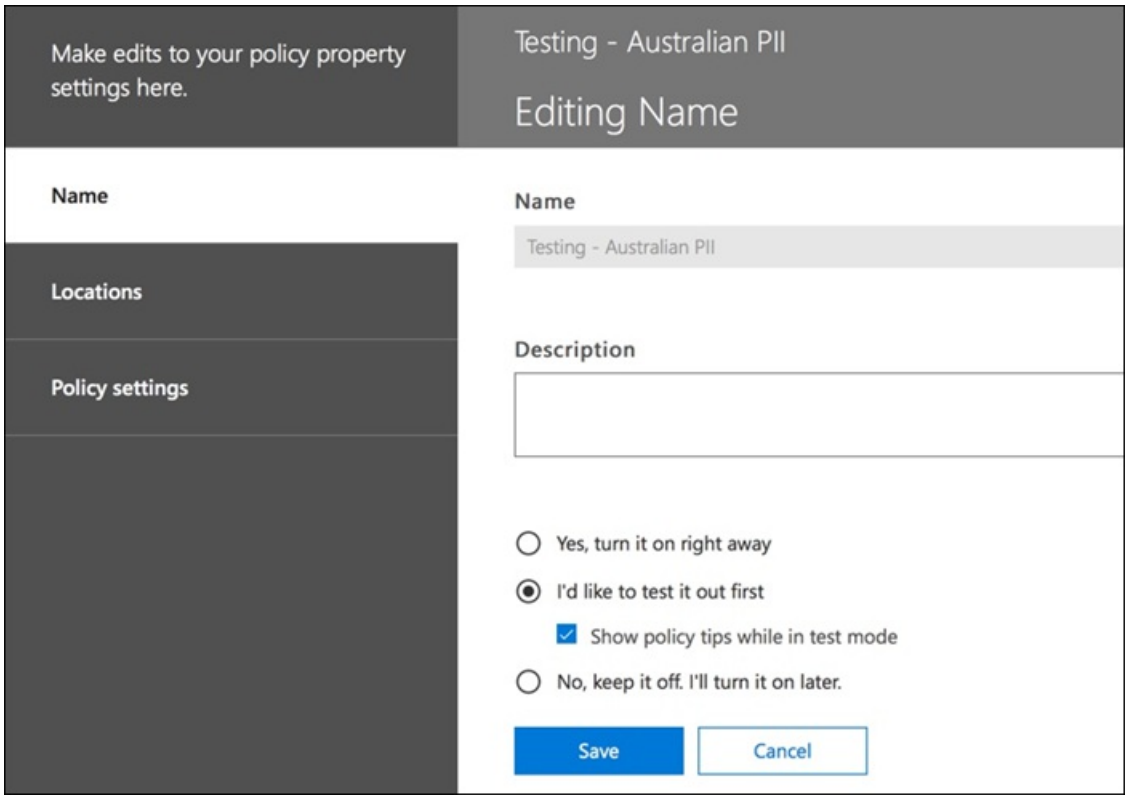
The policy contains two rules for handling of high volume and low volume, so be sure to edit both with the actions that you want. This is an opportunity to treat cases differently depending on their characteristics. For example, you might allow overrides for low volume violations, but not allow overrides for high volume violations.



Also, if you want to actually block or restrict access to content that is in violation of policy, you need to configure an action on the rule to do so.

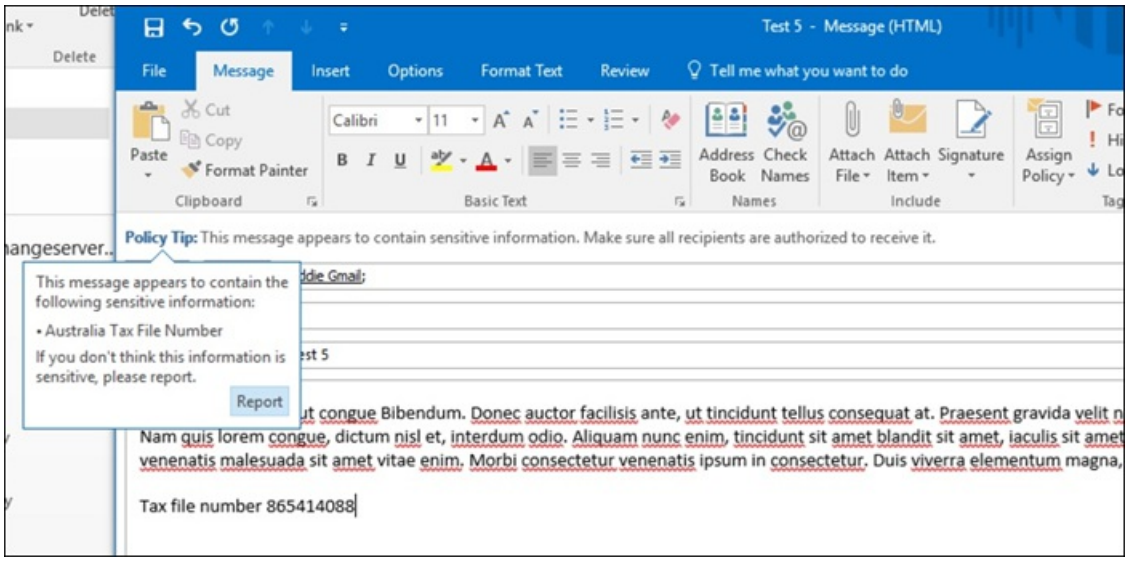


After saving those changes to the policy settings, I also need to return to the main settings page for the policy and enable the option to show policy tips to users while the policy is in test mode. This is an effective way to introduce DLP policies to your end users, and do user awareness training, without risking too many false positives that impact their productivity.



On the server side (or cloud side if you prefer), the change may not take effect immediately, due to various processing intervals. If you're making a DLP policy change that will display new policy tips to a user, the user may not see the changes take effect immediately in their Outlook client, which checks for policy changes every 24 hours. If you want to speed things up for testing, you can use this registry fix to clear the last download time stamp from the PolicyNudges key. Outlook will download the latest policy information the next time you restart it and begin composing an email message.

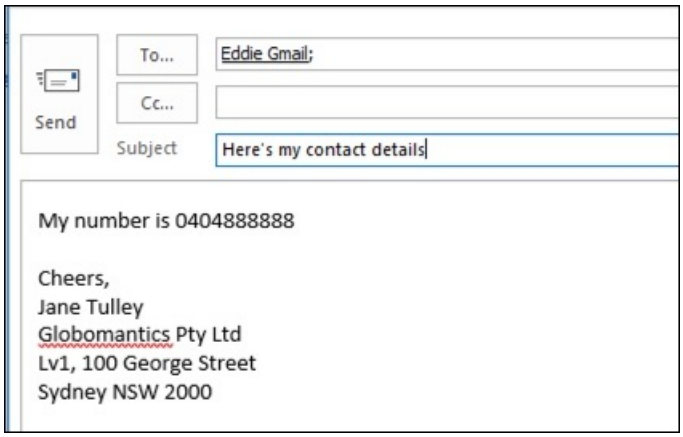
If you have policy tips enabled, the user will begin to see the tips in Outlook, and can report false positives to you when they occur.



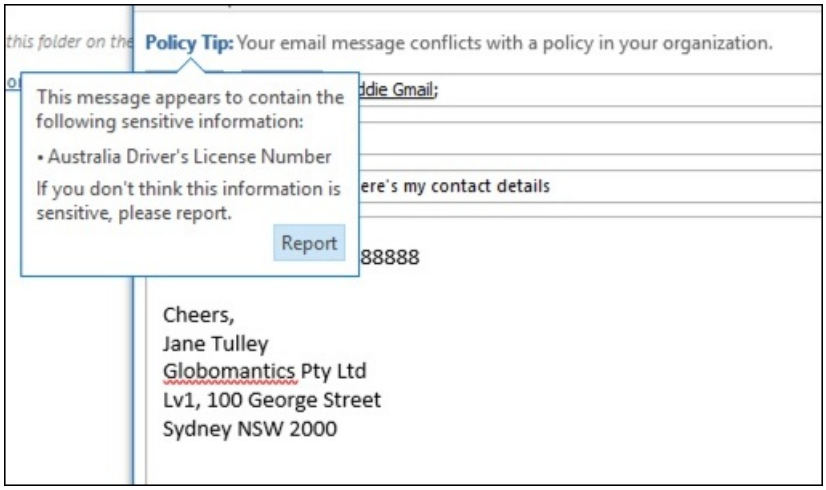
Investigate false positives

DLP policy templates are not perfect straight out of the box. It's likely that you'll find some false positives occurring in your environment, which is why it's so important to ease your way into a DLP deployment, taking the time to adequately test and tune your policies.

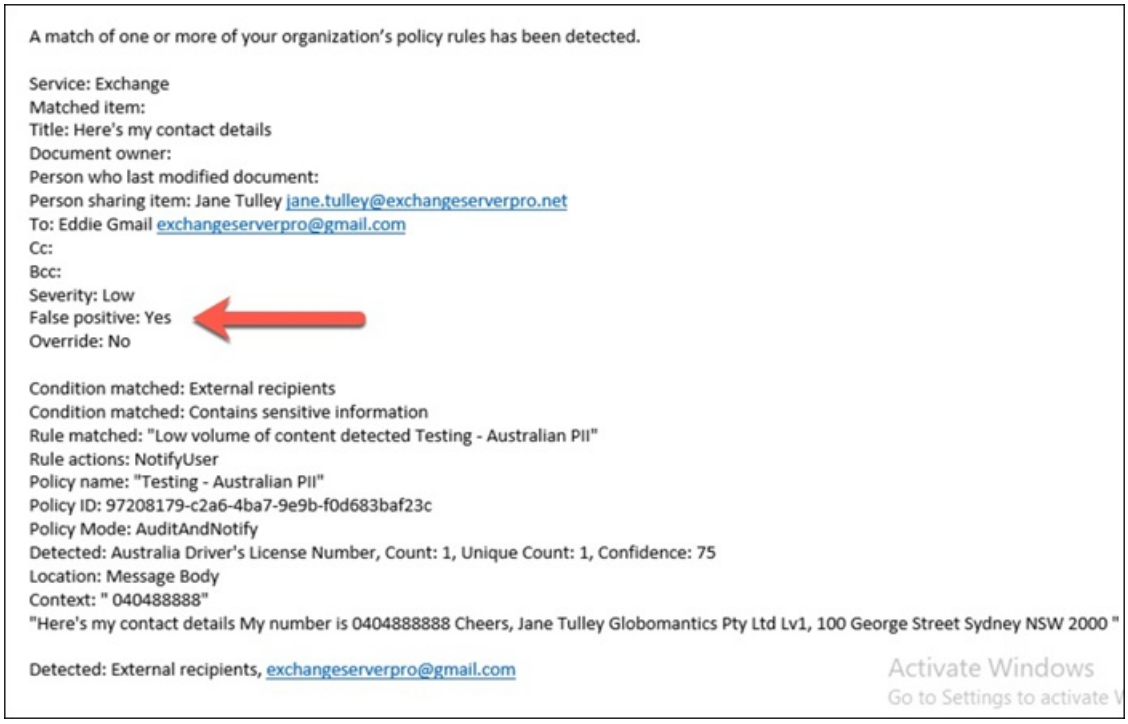
Here's an example of a false positive. This email is quite harmless. The user is providing their mobile phone number to someone, and including their email signature.



But the user sees a policy tip warning them that the email contains sensitive information, specifically, an Australian driver's license number.

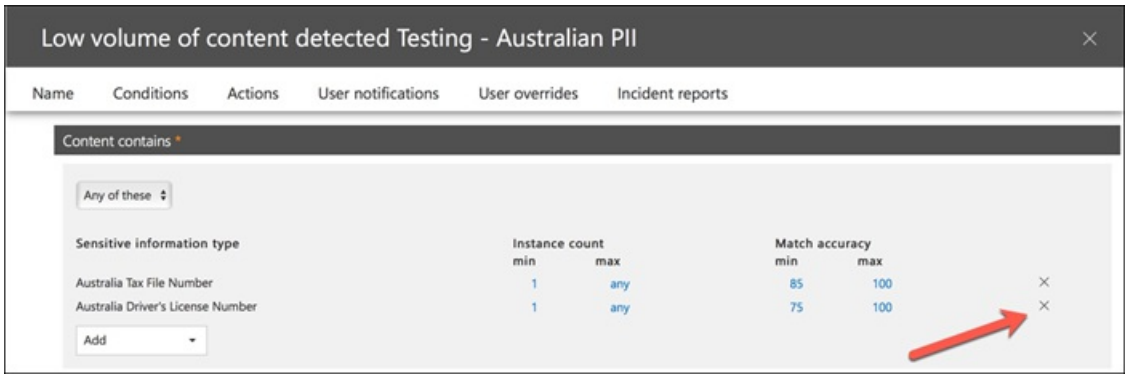


The user can report the false positive, and the administrator can look into why it has occurred. In the incident report email, the email is flagged as a false positive.

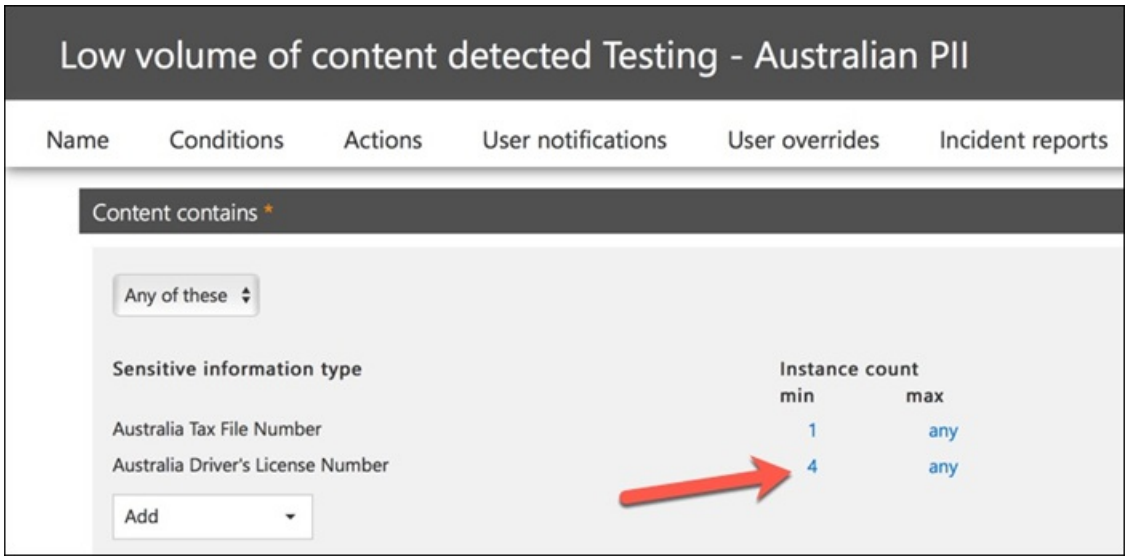


This driver's license case is a good example to dig into. The reason this false positive has occurred is that the "Australian Driver's License" type will be triggered by any 9-digit string (even one that is part of a 10-digit string), within 300 characters proximity to the keywords "sydney nsw" (not case sensitive). So it's triggered by the phone number and email signature, only because the user happens to be in Sydney.

One option is to remove the Australian driver's license information type from the policy. It's in there because it's part of the DLP policy template, but we're not forced to use it. If you're only interested in Tax File Numbers and not driver's licenses, you can just remove it. For example, you can remove it from the low volume rule in the policy, but leave it in the high volume rule so that lists of multiple drivers licenses are still detected.



Another option is to simply increase the instance count, so that a low volume of driver's licenses is only detected when there are multiple instances.

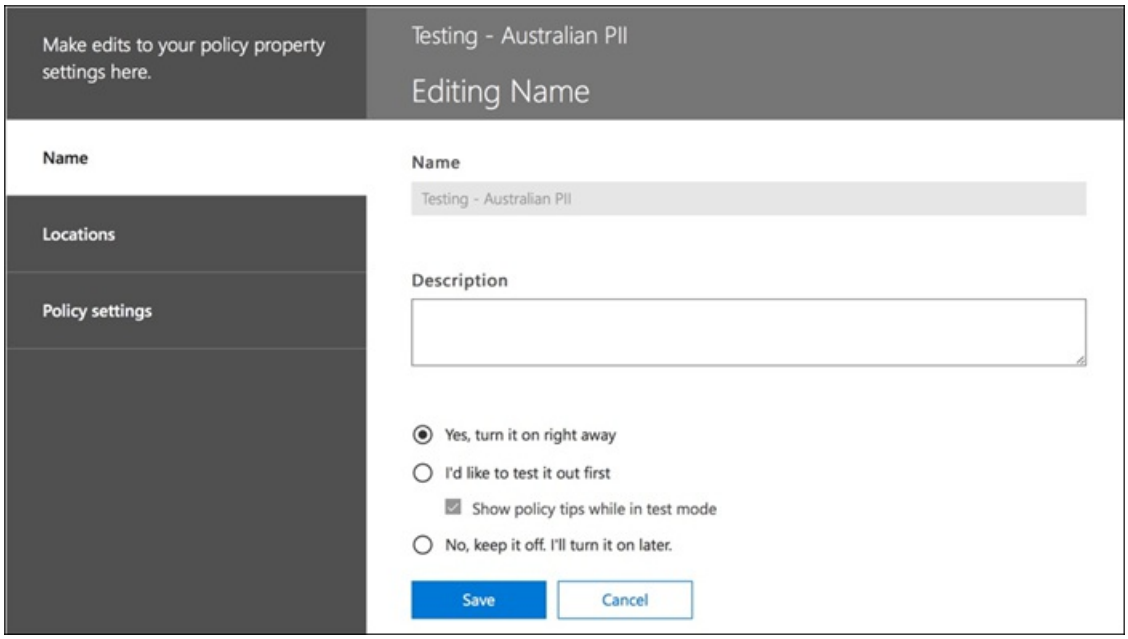


In addition to changing the instance count, you can also adjust the match accuracy (or confidence level). If your sensitive information type has multiple patterns, you can adjust the match accuracy in your rule, so that your rule matches only specific patterns. For example, to help reduce false positives, you can set the match accuracy of your rule so that it matches only the pattern with the highest confidence level. Understanding how confidence level is calculated is a bit tricky (and beyond the scope of this post), but here's a good explanation of how to use confidence level to tune your rules.

Finally, if you want to get even a bit more advanced, you can customize any sensitive information type -- for example, you can remove "Sydney NSW" from the list of keywords for Australia driver's license number, to eliminate the false positive triggered above. To learn how to do this by using XML and PowerShell, see customizing a built-in sensitive information type.

Turn on a DLP policy

When you're happy that your DLP policy is accurately and effectively detecting sensitive information types, and that your end users are ready to deal with the policies being in place, then you can enable the policy.



If you're waiting to see when the policy will take effect, Connect to Security & Compliance Center PowerShell and run the Get-DlpCompliancePolicy cmdlet to see the DistributionStatus.

```
PS C:\> Connect-IPPSSession

PS C:\> Get-DlpCompliancePolicy "Testing - Australian PII" | Select DistributionStatus

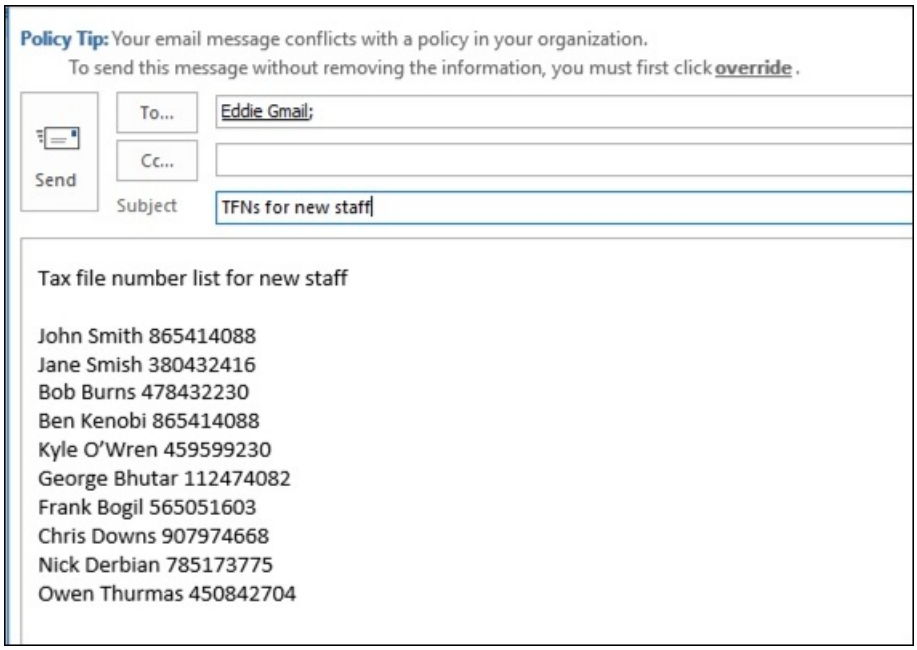
DistributionStatus
------------------
Pending

PS C:\> Get-DlpCompliancePolicy "Testing - Australian PII" | Select DistributionStatus

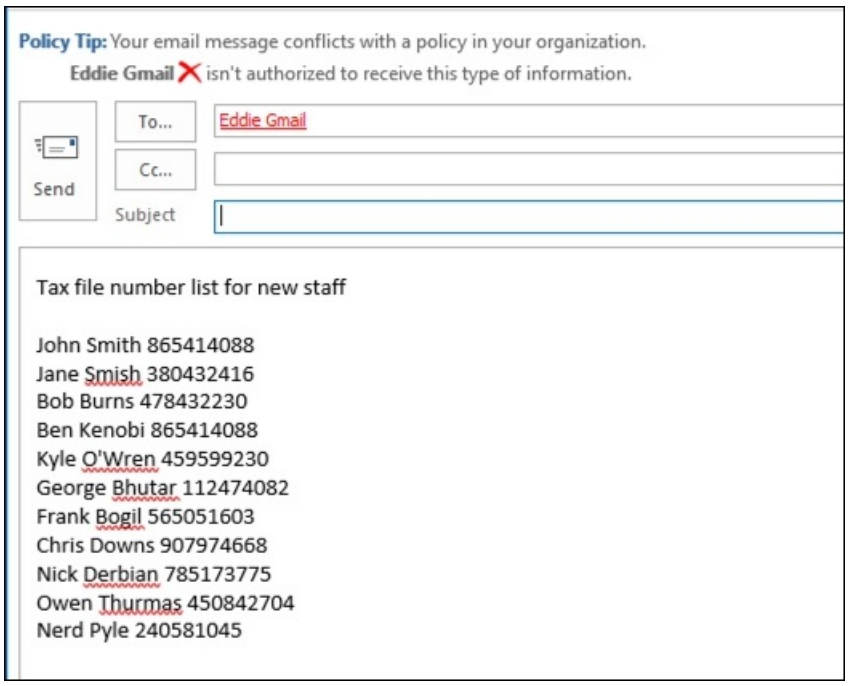
DistributionStatus
------------------
Success
```

After turning on the DLP policy, you should run some final tests of your own to make sure that the expected policy actions are occurring. If you're trying to test things like credit card data, there are websites online with information on how to generate sample credit card or other personal information that will pass checksums and trigger your policies.

Policies that allow user overrides will present that option to the user as part of the policy tip.



Policies that restrict content will present the warning to the user as part of the policy tip, and prevent them from sending the email.



Summary

Data loss prevention policies are useful for organizations of all types. Testing some DLP policies is a low risk exercise due to the control you have over things like policy tips, end user overrides, and incident reports. You can quietly test some DLP policies to see what type of violations are already occurring in your organization, and then craft policies with low false positive rates, educate your users on what is allowed and not allowed, and then roll out your DLP policies to the organization.

Get started with Endpoint data loss prevention

2/18/2021 • 7 minutes to read • Edit Online

Microsoft Endpoint data loss prevention (Endpoint DLP) is part of the Microsoft 365 data loss prevention (DLP) suite of features you can use to discover and protect sensitive items across Microsoft 365 services. For more information about all of Microsoft's DLP offerings, see Overview of data loss prevention. To learn more about Endpoint DLP, see Learn about Endpoint data loss prevention

Microsoft Endpoint DLP allows you to monitor Windows 10 devices and detect when sensitive items are used and shared. This gives you the visibility and control you need to ensure that they are used and protected properly, and to help prevent risky behavior that might compromise them.

Before you begin

SKU/subscriptions licensing

Before you get started with Endpoint DLP, you should confirm your Microsoft 365 subscription and any add-ons. To access and use Endpoint DLP functionality, you must have one of these subscriptions or add-ons.

- Microsoft 365 E5
- Microsoft 365 A5 (EDU)
- Microsoft 365 E5 compliance
- Microsoft 365 A5 compliance
- Microsoft 365 E5 information protection and governance
- Microsoft 365 A5 information protection and governance

Permissions

To enable device management, the account you use must be a member of any one of these roles:

- Global admin
- Security admin
- Compliance admin

If you want to use a custom account to view the device management settings, it must be in one of these roles:

- Global admin
- Compliance admin
- Compliance data admin
- Global reader

If you want to use a custom account to access the onboarding/offboarding page, it must be in one of these roles:

- Global admin
- Compliance admin

If you want to use a custom account to turn on/off device monitoring, it must be in one of these roles:

- Global admin
- Compliance admin

Data from Endpoint DLP can be viewed in Activity explorer. There are four roles that grant permission to activity explorer, the account you use for accessing the data must be a member of any one of them.

- Global admin
- Compliance admin
- Security admin
- Compliance data admin
- Global reader
- Security reader
- Reports reader

Prepare your endpoints

Make sure that the Windows 10 devices that you plan on deploying Endpoint DLP to meet these requirements.

1. Must be running Windows 10 x64 build 1809 or later.
2. Antimalware Client Version is 4.18.2009.7 or newer. Check your current version by opening Windows Security app, select the Settings icon, and then select About. The version number is listed under Antimalware Client Version. Update to the latest Antimalware Client Version by installing Windows Update KB4052623.

   > **NOTE**
   > None of Windows Security components need to be active, you can run Endpoint DLP independent of Windows Security status, but the Real-time protection and Behavior monitor) must be enabled.

3. The following Windows Updates are installed.

   > **NOTE**
   > These updates are not a pre-requisite to onboard a device to Endpoint DLP, but contain fixes for important issues thus must be installed before using the product.

   - For Windows 10 1809 - KB4559003, KB4577069, KB4580390
   - For Windows 10 1903 or 1909 - KB4559004, KB4577062, KB4580386
   - For Windows 10 2004 - KB4568831, KB4577063
   - For devices running Office 2016 (and not any other Office version) - KB4577063
4. All devices must be Azure Active Directory (Azure AD) joined, or Hybrid Azure AD joined.
5. Install Microsoft Chromium Edge browser on the endpoint device to enforce policy actions for the upload to cloud activity. See, Download the new Microsoft Edge based on Chromium.
6. If you are on Monthly Enterprise Channel of Microsoft 365 Apps versions 2004-2008, there is a known issue with Endpoint DLP classifying Office content and you need to update to version 2009 or later. See Update history for Microsoft 365 Apps (listed by date) for current versions. To learn more about this issue, see the Office Suite section of Release notes for Current Channel releases in 2020.
7. If you have endpoints that use a device proxy to connect to the internet, follow the procedures in Configure device proxy and internet connection settings for Endpoint DLP.

Onboarding devices into device management

You must enable device monitoring and onboard your endpoints before you can monitor and protect sensitive items on a device. Both of these actions are done in the Microsoft 365 Compliance portal.

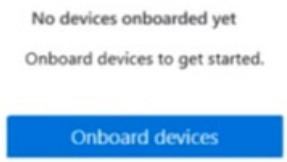
When you want to onboard devices that haven't been onboarded yet, you'll download the appropriate script and deploy it to those devices. Follow the Onboarding devices procedure.

If you already have devices onboarded into Microsoft Defender for Endpoint, they will already appear in the managed devices list. Follow the With devices onboarded into Microsoft Defender for Endpoint procedure.

Onboarding devices

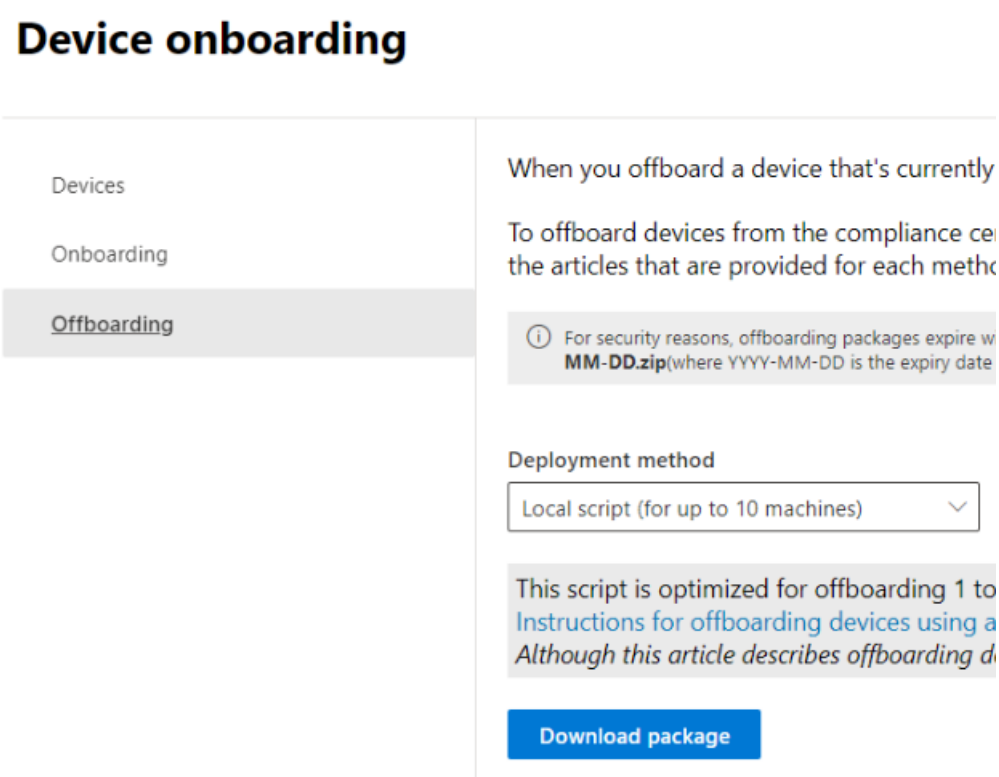
In this deployment scenario, you'll onboard devices that have not been onboarded yet, and you just want to monitor and protect sensitive items from unintentional sharing on Windows 10 devices.

1. Open the Microsoft compliance center.
2. Open the Compliance Center settings page and choose **Onboard devices**.



> **NOTE**
> While it usually takes about 60 seconds for device onboarding to be enabled, please allow up to 30 minutes before engaging with Microsoft support.

3. Choose **Device management** to open the **Devices** list. The list will be empty until you onboard devices.
4. Choose **Onboarding** to begin the onboarding process.
5. Choose the way you want to deploy to these additional devices from the **Deployment method** list and then **download package**.



6. Follow the appropriate procedures in Onboarding tools and methods for Windows 10 machines. This link takes you to a landing page where you can access Microsoft Defender for Endpoint procedures that match the deployment package you selected in step 5:
   - Onboard Windows 10 machines using Group Policy
   - Onboard Windows machines using Microsoft Endpoint Configuration Manager

- Onboard Windows 10 machines using Mobile Device Management tools
- Onboard Windows 10 machines using a local script
- Onboard non-persistent virtual desktop infrastructure (VDI) machines.

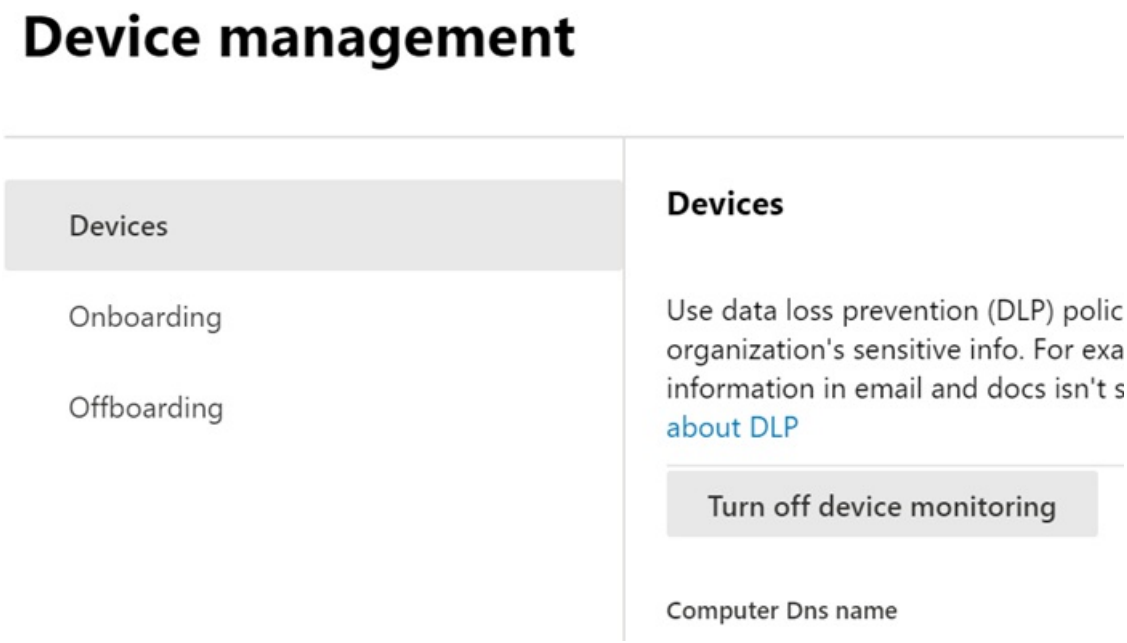
Once done and endpoint is onboarded, it should be visible in the devices list and also start reporting audit activity logs to Activity explorer.

> **NOTE**
> This experience is under license enforcement. Without the required license, data will not be visible or accessible.

With devices onboarded into Microsoft Defender for Endpoint

In this scenario, Microsoft Defender for Endpoint is already deployed and there are endpoints reporting in. All these endpoints will appear in the managed devices list. You can continue to onboard new devices into Endpoint DLP to expand coverage by using the Onboarding devices procedure.

1. Open the Microsoft compliance center.
2. Open the Compliance Center settings page and choose **Enable device monitoring**.
3. Choose **Device management** to open the **Devices** list. You should see the list of devices that are already reporting in to Microsoft Defender for Endpoint.



4. Choose **Onboarding** if you need to onboard additional devices.
5. Choose the way you want to deploy to these additional devices from the **Deployment method** list and then **Download package**.
6. Follow the appropriate procedures in Onboarding tools and methods for Windows 10 machines. This link takes you to a landing page where you can access Microsoft Defender for Endpoint procedures that match the deployment package you selected in step 5:

   - Onboard Windows 10 machines using Group Policy
   - Onboard Windows machines using Microsoft Endpoint Configuration Manager
   - Onboard Windows 10 machines using Mobile Device Management tools
   - Onboard Windows 10 machines using a local script
   - Onboard non-persistent virtual desktop infrastructure (VDI) machines.

Once done and endpoint is onboarded, it should be visible under the **Devices** table and also start reporting audit logs to the **Activity Explorer**.

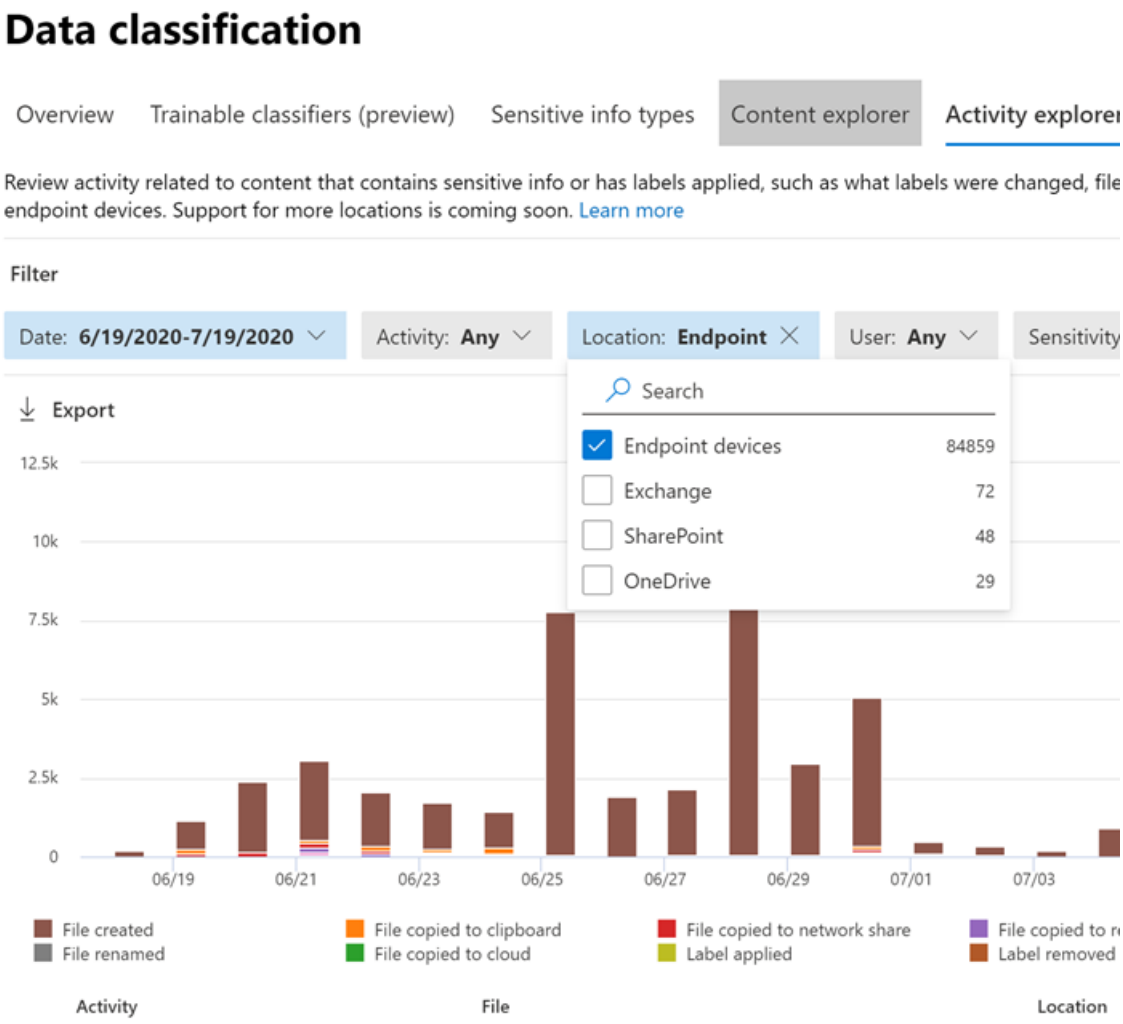
> **NOTE**
>
> This experience is under license enforcement. Without the required license, data will not be visible or accessible.

Viewing Endpoint DLP alerts in DLP Alerts Management dashboard

1. Open the Data loss prevention page in the Microsoft 365 Compliance center and choose Alerts.
2. Refer to the procedures in How to configure and view alerts for your DLP policies to view alerts for your Endpoint DLP policies.

Viewing Endpoint DLP data in activity explorer

1. Open the Data classification page for your domain in the Microsoft 365 Compliance center and choose Activity explorer.
2. Refer to the procedures in Get started with Activity explorer to access and filter all the data for your Endpoint devices.



Next steps

Now that you have onboarded devices and can view the activity data in Activity explorer, you are ready to move on to your next step where you create DLP policies that protect your sensitive items.

Configure device proxy and internet connection settings for Endpoint DLP

2/18/2021 • 5 minutes to read • Edit Online

Microsoft Endpoint DLP uses Microsoft Windows HTTP (WinHTTP) to report data and communicate with the Microsoft endpoint cloud service. The embedded Endpoint DLP runs in system context using the LocalSystem account.

> **TIP**
>
> For organizations that use forward proxies as a gateway to the Internet, you can use network protection to investigate behind a proxy. For more information, see Investigate connection events that occur behind forward proxies.

The WinHTTP configuration setting is independent of the Windows Internet (WinINet) Internet browsing proxy settings and can only discover a proxy server by using the following auto discovery methods:

- Transparent proxy
- Web Proxy Auto-discovery Protocol (WPAD)

> **NOTE**
>
> If you're using Transparent proxy or WPAD in your network topology, you don't need special configuration settings. For more information on Defender for Endpoint URL exclusions in the proxy, see Enable access to Endpoint DLP cloud service URLs in the proxy server.

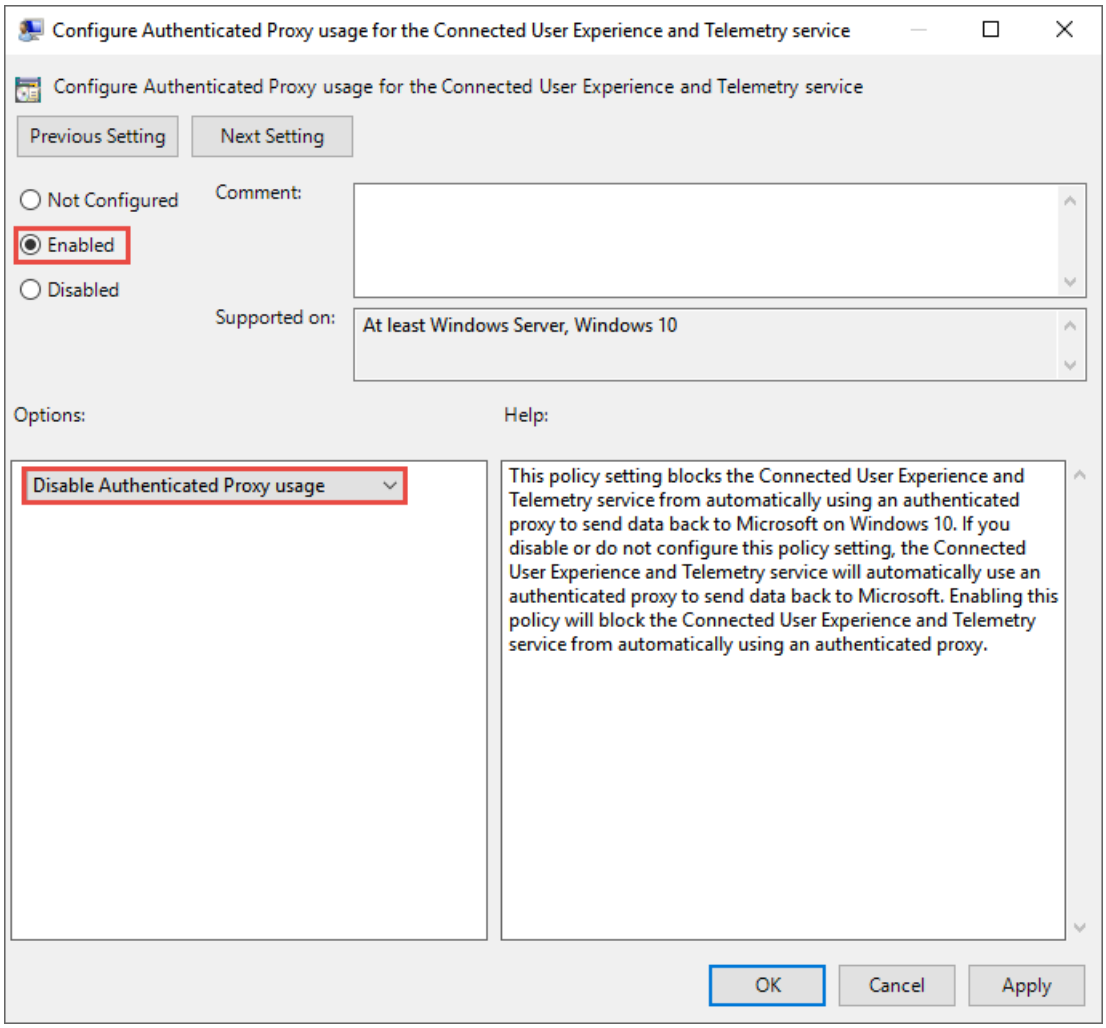
- Manual static proxy configuration:
  - Registry based configuration
  - WinHTTP configured using netsh command – Suitable only for desktops in a stable topology (for example: a desktop in a corporate network behind the same proxy)

Configure the proxy server manually using a registry-based static proxy

For endpoint devices that aren't permitted to connect to the Internet, you need to configure a registry-based static proxy. You need to configure this to allow only Microsoft Endpoint DLP to report diagnostic data and communicate with Microsoft endpoint cloud service.

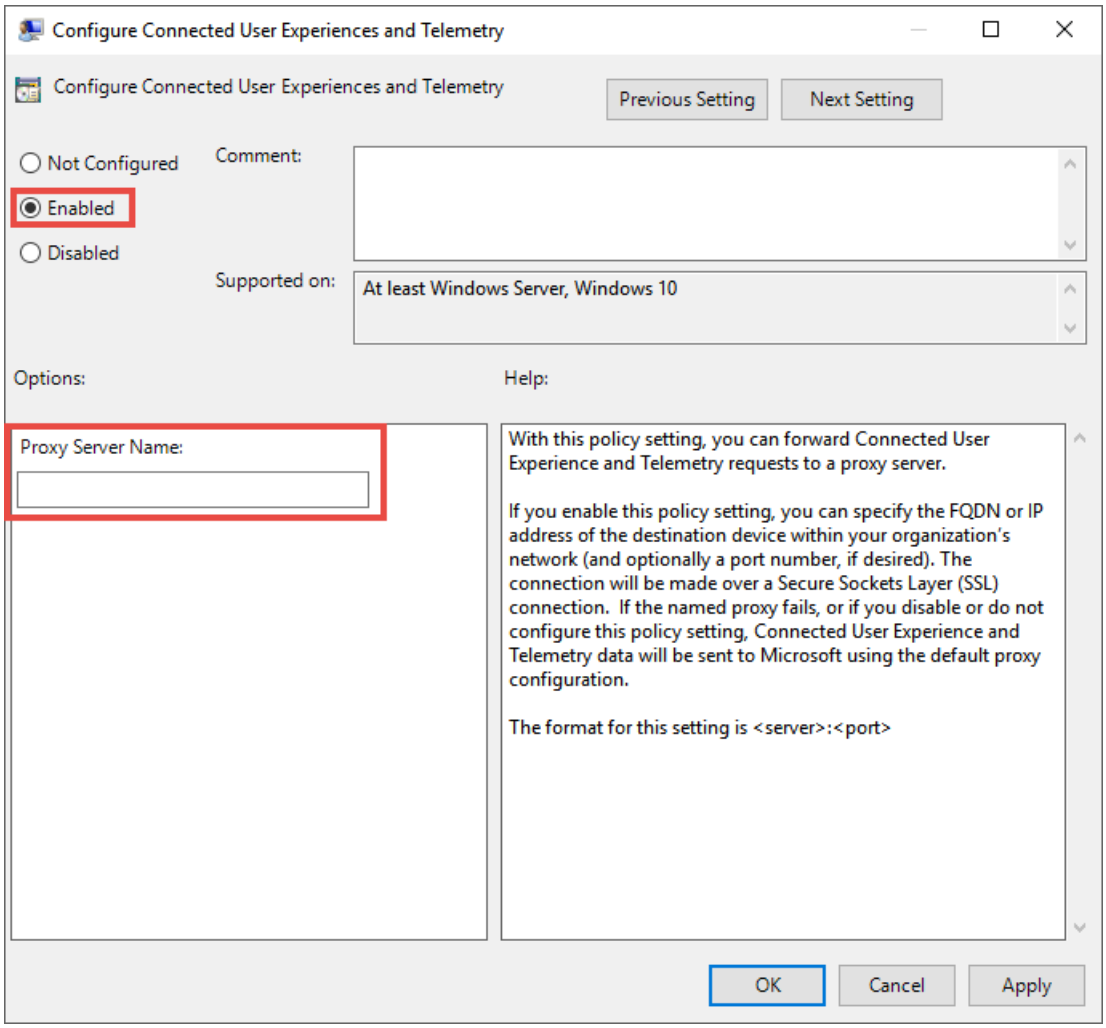
The static proxy is configurable through Group Policy (GP). The group policy can be found under:

1. Open **Administrative Templates > Windows Components > Data Collection and Preview Builds > Configure Authenticated Proxy usage for the Connected User Experience and Telemetry Service**
2. Set it to **Enabled** and select **Disable Authenticated Proxy usage**:



3. Open **Administrative Templates > Windows Components > Data Collection and Preview Builds > Configure connected user experiences and telemetry**:

Configure the proxy



The policy sets two registry values `TelemetryProxyServer` as REG_SZ and `DisableEnterpriseAuthProxy` as REG_DWORD under the registry key `HKLM\Software\Policies\Microsoft\Windows\DataCollection`.

The registry value TelemetryProxyServer is in this format <server name or ip>:<port>. For example: **10.0.0.6:8080**

The registry value `DisableEnterpriseAuthProxy` should be set to 1.

Configure the proxy server manually using "netsh" command

Use netsh to configure a system-wide static proxy.

> **NOTE**
> This will affect all applications including Windows services which use WinHTTP with default proxy. - Laptops that are changing topology (for example: from office to home) will malfunction with netsh. Use the registry-based static proxy configuration.

1. Open an elevated command-line:
   a. Go to **Start** and type **cmd**
   b. Right-click **Command prompt** and select **Run as administrator**.
2. Enter the following command and press **Enter**:

   ```
   netsh winhttp set proxy <proxy>:<port>
   ```

   For example: **netsh winhttp set proxy 10.0.0.6:8080**

3. To reset the winhttp proxy, enter the following command and press **Enter**:

```
netsh winhttp reset proxy
```

See Netsh Command Syntax, Contexts, and Formatting to learn more.

Enable access to Endpoint DLP cloud service URLs in the proxy server

If a proxy or firewall is blocking all traffic by default and allowing only specific domains through, add the domains listed in the downloadable sheet to the allowed domains list.

This downloadable spreadsheet lists the services and their associated URLs that your network must be able to connect to. You should ensure that there are no firewall or network filtering rules that would deny access to these URLs, or you may need to create an allow rule specifically for them.

If a proxy or firewall has HTTPS scanning (SSL inspection) enabled, exclude the domains listed in the above table from HTTPS scanning. If a proxy or firewall is blocking anonymous traffic, as Endpoint DLP is connecting from system context, make sure anonymous traffic is permitted in the previously listed URLs.

Verify client connectivity to Microsoft cloud service URLs

Verify the proxy configuration completed successfully, that WinHTTP can discover and communicate through the proxy server in your environment, and that the proxy server allows traffic to the Defender for Endpoint service URLs.

1. Download the MDATP Client Analyzer tool to the PC where Endpoint DLP is running on.
2. Extract the contents of MDATPClientAnalyzer.zip on the device.
3. Open an elevated command-line:
   a. Go to **Start** and type **cmd**.
   b. Right-click **Command prompt** and select **Run as administrator**.
4. Enter the following command and press **Enter**:

```
HardDrivePath\MDATPClientAnalyzer.cmd
```

Replace *HardDrivePath* with the path where the MDATPClientAnalyzer tool was downloaded to, for example

C:\Work\tools\MDATPClientAnalyzer\MDATPClientAnalyzer.cmd

5. Extract the **MDATPClientAnalyzerResult.zip*** file created by tool in the folder used in the *HardDrivePath*.

6. Open **MDATPClientAnalyzerResult.txt** and verify that you have performed the proxy configuration steps to enable server discovery and access to the service URLs. The tool checks the connectivity of Defender for Endpoint service URLs that Defender for Endpoint client is configured to interact with. It then prints the results into the **MDATPClientAnalyzerResult.txt** file for each URL that can potentially be used to communicate with the Defender for Endpoint services. For example:

   Testing URL : https://xxx.microsoft.com/xxx
   1 - Default proxy: Succeeded (200)
   2 - Proxy auto discovery (WPAD): Succeeded (200)
   3 - Proxy disabled: Succeeded (200)
   4 - Named proxy: Doesn't exist
   5 - Command line proxy: Doesn't exist

If at least one of the connectivity options returns a (200) status, then the Defender for Endpoint client can communicate with the tested URL properly using this connectivity method.

However, if the connectivity check results indicate a failure, an HTTP error is displayed (see HTTP Status Codes). You can then use the URLs in the table shown in Enable access to Endpoint DLP cloud service URLs in the proxy server. The URLs you'll use will depend on the region selected during the onboarding procedure. [!NOTE] The Connectivity Analyzer tool is not compatible with ASR rule Block process creations originating from PSExec and WMI commands. You will need to temporarily disable this rule to run the connectivity tool.

[!NOTE] When the TelemetryProxyServer is set, in Registry or via Group Policy, Defender for Endpoint will fall back to direct if it can't access the defined proxy. Related topics • Onboard Windows 10 devices • Troubleshoot Microsoft Endpoint DLP onboarding issues

Onboarding tools and methods for Windows 10 devices

2/18/2021 • 2 minutes to read • Edit Online

Applies to:

- Microsoft 365 Endpoint data loss prevention (DLP)

Devices in your organization must be configured so that the Microsoft 365 Endpoint data loss prevention service can get sensor data from them. There are various methods and deployment tools that you can use to configure the devices in your organization.

The following deployment tools and methods are supported:

- group policy
- Microsoft Endpoint Configuration Manager
- Mobile Device Management (including Microsoft Intune)
- local script

In this section

TOPIC	DESCRIPTION
Onboard Windows 10 devices using Group Policy	Use Group Policy to deploy the configuration package on devices.
Onboard Windows devices using Microsoft Endpoint Configuration Manager	You can use either use Microsoft Endpoint Configuration Manager (current branch) version 1606 or Microsoft Endpoint Configuration Manager (current branch) version 1602 or earlier to deploy the configuration package on devices.
Onboard Windows 10 devices using Mobile Device Management tools	Use Mobile Device Management tools or Microsoft Intune to deploy the configuration package on device.
Onboard Windows 10 devices using a local script	Learn how to use the local script to deploy the configuration package on endpoints.
Onboard non-persistent virtual desktop infrastructure (VDI) devices	Learn how to use the configuration package to configure VDI devices.

Onboard Windows 10 devices using Group Policy

11/2/2020 • 3 minutes to read • Edit Online

Applies to:

- Microsoft 365 Endpoint data loss prevention (DLP)
- Group Policy

> **NOTE**
> To use Group Policy (GP) updates to deploy the package, you must be on Windows Server 2008 R2 or later.

> For Windows Server 2019, you may need to replace NT AUTHORITY\Well-Known-System-Account with NT AUTHORITY\SYSTEM of the XML file that the Group Policy preference creates.

Onboard devices using Group Policy

1. Open the GP configuration package .zip file (*DeviceComplianceOnboardingPackage.zip*) that you downloaded from the service onboarding wizard. You can also get the package from Microsoft Compliance center
2. In the navigation pane, select **Settings** > **Device Onboarding**.
3. In the **Deployment method** field, select **Group policy**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the device. You should have a folder called *OptionalParamsPolicy* and the file *DeviceComplianceLocalOnboardingScript.cmd*.
6. Open the Group Policy Management Console (GPMC), right-click the Group Policy Object (GPO) you want to configure and click **Edit**.
7. In the **Group Policy Management Editor**, go to **Computer configuration**, then **Preferences**, and then **Control panel settings**.
8. Right-click **Scheduled tasks**, point to **New**, and then click **Immediate Task (At least Windows 7)**.
9. In the **Task** window that opens, go to the **General** tab. Under **Security options** click **Change User or Group** and type SYSTEM and then click **Check Names** then **OK**. NT AUTHORITY\SYSTEM appears as the user account the task will run as.
10. Select **Run whether user is logged on or not** and check the **Run with highest privileges** check box.
11. Go to the **Actions** tab and click **New...** Ensure that **Start a program** is selected in the **Action** field. Enter the file name and location of the shared *WindowsDefenderATPOnboardingScript.cmd* file.
12. Click **OK** and close any open GPMC windows.

Offboard devices using Group Policy

For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When downloading an offboarding package you will be notified of the packages expiry date and it will also be included in the package name.

> **NOTE**
> Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this will cause unpredictable collisions.

1. Get the offboarding package from Microsoft Compliance center.
2. In the navigation pane, select **Settings** > **//Device onboarding** > **Offboarding**.
3. In the **Deployment method** field, select **Group policy**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the device. You should have a file named *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd*.
6. Open the Group Policy Management Console (GPMC), right-click the Group Policy Object (GPO) you want to configure and click **Edit**.
7. In the **Group Policy Management Editor**, go to **Computer configuration,** then **Preferences**, and then **Control panel settings**.
8. Right-click **Scheduled tasks**, point to **New**, and then click **Immediate task**.
9. In the **Task** window that opens, go to the **General** tab. Choose the local SYSTEM user account (BUILTIN\SYSTEM) under **Security options**.
10. Select **Run whether user is logged on or not** and check the **Run with highest privileges** check-box.
11. Go to the **Actions** tab and click **New...**. Ensure that **Start a program** is selected in the **Action** field. Enter the file name and location of the shared *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd* file.
12. Click **OK** and close any open GPMC windows.

> **IMPORTANT**
> Offboarding causes the device to stop sending sensor data to the portal but data from the device.

Monitor device configuration

With Group Policy there isn't an option to monitor deployment of policies on the devices. Monitoring can be done directly on the portal, or by using the different deployment tools.

Monitor devices using the portal

1. Go to Microsoft Compliance center.
2. Click **Devices** list.
3. Verify that devices are appearing.

NOTE

It can take several days for devices to start showing on the **Devices list**. This includes the time it takes for the policies to be distributed to the device, the time it takes before the user logs on, and the time it takes for the endpoint to start reporting.

Onboard Windows 10 devices using Mobile Device Management tools

11/2/2020 • 2 minutes to read • Edit Online

Applies to:

- Microsoft 365 Endpoint data loss prevention (DLP)

You can use mobile device management (MDM) solutions to configure devices. Microsoft 365 Endpoint data loss prevention supports MDMs by providing OMA-URIs to create policies to manage devices.

Before you begin

If you're using Microsoft Intune, you must have the device MDM Enrolled. Otherwise, settings will not be applied successfully.

For more information on enabling MDM with Microsoft Intune, see Device enrollment (Microsoft Intune).

Onboard devices using Microsoft Intune

Follow the instructions from Intune.

> **NOTE**
> - The **Health Status for onboarded devices** policy uses read-only properties and can't be remediated.

Offboard and monitor devices using Mobile Device Management tools

For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When downloading an offboarding package you will be notified of the packages expiry date and it will also be included in the package name.

> **NOTE**
> Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this will cause unpredictable collisions.

1. Get the offboarding package from Microsoft Compliance center.
2. In the navigation pane, select **Settings** > **Device onboarding** > **Offboarding**.
3. In the **Deployment method** field, select **Mobile Device Management / Microsoft Intune**.
4. Click **Download package**, and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the network administrators who will deploy the package. You should have a file named *DeviceCompliance_valid_until_YYYY-MM-DD.offboarding*.
6. Use the Microsoft Intune custom configuration policy to deploy the following supported OMA-URI

settings.

OMA-URI: ./Device/Vendor/MSFT/WindowsAdvancedThreatProtection/Offboarding
Date type: String
Value: [Copy and paste the value from the content of the DeviceCompliance_valid_until_YYYY-MM-DD.offboarding file]

For more information on Microsoft Intune policy settings see, Windows 10 policy settings in Microsoft Intune.

> **NOTE**
> The **Health Status for offboarded devices** policy uses read-only properties and can't be remediated.

> **IMPORTANT**
> Offboarding causes the device to stop sending sensor data to the portal but data from the device, including reference to any alerts it has had will be retained for up to 6 months.

Related topics

- Onboard Windows 10 devices using Group Policy

Onboard Windows 10 devices using Configuration Manager

11/2/2020 • 6 minutes to read • Edit Online

Applies to:

- Microsoft 365 Endpoint data loss prevention (DLP)
- System Center 2012 R2 Configuration Manager

Onboard devices using System Center Configuration Manager

1. Open the Configuration Manager configuration package .zip file (*DeviceComplianceOnboardingPackage.zip*) that you downloaded from the service onboarding wizard. You can also get the package from Microsoft Compliance center.
2. In the navigation pane, select **Settings** > **Device Onboarding** > **Onboarding**.
3. In the **Deployment method** field, select **Microsoft Endpoint Configuration Manager 2012/2012 R2/1511/1602**.
4. Select **Download package**, and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the network administrators who will deploy the package. You should have a file named *DeviceComplianceOnboardingScript.cmd*.
6. Deploy the package by following the steps in the Packages and Programs in System Center 2012 R2 Configuration Manager article.
7. Choose a predefined device collection to deploy the package to.

> **NOTE**
> Microsoft 365 Endpoint data loss prevention doesn't support onboarding during the Out-Of-Box Experience (OOBE) phase. Make sure users complete OOBE after running Windows installation or upgrading.

> **TIP**
> After onboarding the device, you can choose to run a detection test to verify that an device is properly onboarded to the service. For more information, see Run a detection test on a newly onboarded Microsoft Defender ATP device.
>
> Note that it is possible to create a detection rule on a Configuration Manager application to continuously check if a device has been onboarded. An application is a different type of object than a package and program. If a device is not yet onboarded (due to pending OOBE completion or any other reason), Configuration Manager will retry to onboard the device until the rule detects the status change.
>
> This behavior can be accomplished by creating a detection rule checking if the "OnboardingState" registry value (of type REG_DWORD) = 1. This registry value is located under "HKLM\SOFTWARE\Microsoft\Windows Advanced Threat Protection\Status". For more information, see Configure Detection Methods in System Center 2012 R2 Configuration Manager.

Configure sample collection settings

For each device, you can set a configuration value to state whether samples can be collected from the device

when a request is made through Microsoft Defender Security Center to submit a file for deep analysis.

> **NOTE**
> These configuration settings are typically done through Configuration Manager.

You can set a compliance rule for configuration item in Configuration Manager to change the sample share setting on a device.

This rule should be a *remediating* compliance rule configuration item that sets the value of a registry key on targeted devices to make sure they're complaint.

The configuration is set through the following registry key entry:

```
Path: “HKLM\SOFTWARE\Policies\Microsoft\Windows Advanced Threat Protection”
Name: "AllowSampleCollection"
Value: 0 or 1
```

Where:
Key type is a D-WORD.
Possible values are:

- 0 - doesn't allow sample sharing from this device
- 1 - allows sharing of all file types from this device

The default value in case the registry key doesn't exist is 1.

For more information about System Center Configuration Manager Compliance, see Introduction to compliance settings in System Center 2012 R2 Configuration Manager.

Other recommended configuration settings

After onboarding devices to the service, it's important to take advantage of the included threat protection capabilities by enabling them with the following recommended configuration settings.

Device collection configuration

If you're using Endpoint Configuration Manager, version 2002 or later, you can choose to broaden the deployment to include servers or down-level clients.

Next generation protection configuration

The following configuration settings are recommended:

Scan

- Scan removable storage devices such as USB drives: Yes

Real-time Protection

- Enable Behavioral Monitoring: Yes
- Enable protection against Potentially Unwanted Applications at download and prior to installation: Yes

Cloud Protection Service

- Cloud Protection Service membership type: Advanced membership

Attack surface reduction Configure all available rules to Audit.

> **NOTE**
> Blocking these activities may interrupt legitimate business processes. The best approach is setting everything to audit, identifying which ones are safe to turn on, and then enabling those settings on endpoints which do not have false positive detections.

Network protection

Prior to enabling network protection in audit or block mode, ensure that you've installed the antimalware platform update, which can be obtained from the support page.

Controlled folder access

Enable the feature in audit mode for at least 30 days. After this period, review detections and create a list of applications that are allowed to write to protected directories.

For more information, see Evaluate controlled folder access.

Offboard devices using Configuration Manager

For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When downloading an offboarding package, you will be notified of the packages expiry date and it will also be included in the package name.

> **NOTE**
> Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this will cause unpredictable collisions.

Offboard devices using Microsoft Endpoint Configuration Manager current branch

If you use Microsoft Endpoint Configuration Manager current branch, see Create an offboarding configuration file.

Offboard devices using System Center 2012 R2 Configuration Manager

1. Get the offboarding package from Microsoft Compliance center:
2. In the navigation pane, select **Settings** > **Device onboarding** > **Offboarding**.
3. Select Windows 10 as the operating system.
4. In the **Deployment method** field, select **Microsoft Endpoint Configuration Manager 2012/2012 R2/1511/1602**.
5. Select **Download package**, and save the .zip file.
6. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the network administrators who will deploy the package. You should have a file named *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd*.
7. Deploy the package by following the steps in the Packages and Programs in System Center 2012 R2 Configuration Manager article.
8. Choose a predefined device collection to deploy the package to.

IMPORTANT

Offboarding causes the device to stop sending sensor data to the portal but data from the device, including reference to any alerts it has had will be retained for up to 6 months.

Monitor device configuration

If you're using Microsoft Endpoint Configuration Manager current branch, use the built-in Microsoft Defender ATP dashboard in the Configuration Manager console. For more information, see Microsoft Defender Advanced Threat Protection - Monitor.

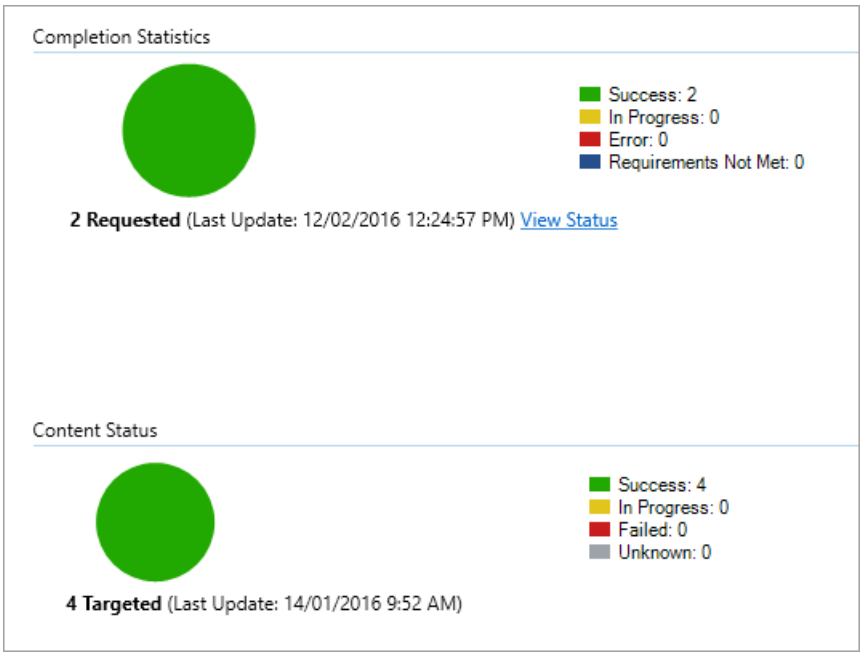
If you're using System Center 2012 R2 Configuration Manager, monitoring consists of two parts:

1. Confirming the configuration package has been correctly deployed and is running (or has successfully run) on the devices in your network.
2. Checking that the devices are compliant with the Microsoft 365 Endpoint data loss prevention service (this ensures the device can complete the onboarding process and can continue to report data to the service).

Confirm the configuration package has been correctly deployed

1. In the Configuration Manager console, click **Monitoring** at the bottom of the navigation pane.
2. Select **Overview** and then **Deployments**.
3. Select on the deployment with the package name.
4. Review the status indicators under **Completion Statistics** and **Content Status**.

   If there are failed deployments (devices with **Error**, **Requirements Not Met**, or **Failed statuses**), you may need to troubleshoot the devices. For more information, see, Troubleshoot Microsoft Defender Advanced Threat Protection onboarding issues.



Check that the devices are compliant with the Microsoft 365 Endpoint data loss prevention service

You can set a compliance rule for configuration item in System Center 2012 R2 Configuration Manager to monitor your deployment.

> **NOTE**
>
> This procedure and registry entry applies to Endpoint DLP as well as Advanced Threat Protection.

This rule should be a *non-remediating* compliance rule configuration item that monitors the value of a registry key on targeted devices.

Monitor the following registry key entry:

```
Path: “HKLM\SOFTWARE\Microsoft\Windows Advanced Threat Protection\Status”
Name: “OnboardingState”
Value: “1”
```

For more information, see Introduction to compliance settings in System Center 2012 R2 Configuration Manager.

Onboard Windows 10 devices using a local script

11/2/2020 • 2 minutes to read • Edit Online

Applies to:

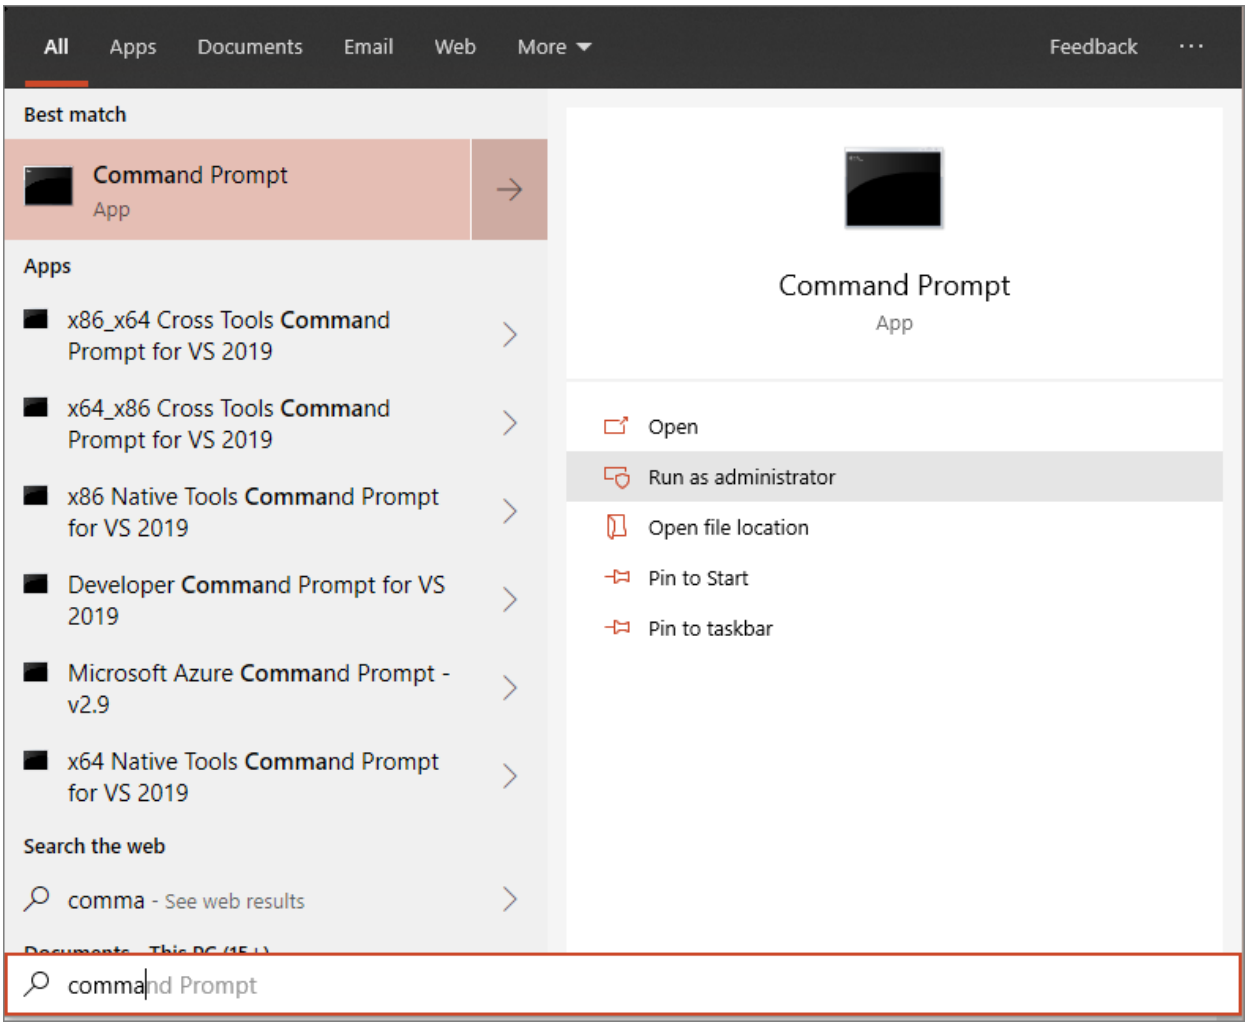
- Microsoft 365 Endpoint data loss prevention (DLP)

You can also manually onboard individual devices to Microsoft 365 Endpoint data loss prevention. You might want to do this first when testing the service before you commit to onboarding all devices in your network.

> **IMPORTANT**
>
> This script has been optimized for use on up to 10 devices.
>
> To deploy at scale, use other deployment options. For example, you can deploy an onboarding script to more than 10 devices in production with the script available in Onboard Windows 10 devices using Group Policy.

Onboard devices

1. Open the GP configuration package .zip file (*DeviceComplianceOnboardingPackage.zip*) that you downloaded from the service onboarding wizard. You can also get the package from Microsoft Compliance center
2. In the navigation pane, select **Settings** > **Device onboarding**.
3. In the **Deployment method** field, select **Local Script**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the configuration package to a location on the device you want to onboard (for example, the Desktop). You should have a file named *DeviceOnboardingScript.cmd*.
6. Open an elevated command-line prompt on the device and run the script:
7. Go to **Start** and type **cmd**.
8. Right-click **Command prompt** and select **Run as administrator**.



9. Type the location of the script file. If you copied the file to the desktop, type: *%userprofile%\Desktop\WindowsDefenderATPOnboardingScript.cmd*
10. Press the **Enter** key or click **OK**.

For information on how you can manually validate that the device is compliant and correctly reports sensor data see, Troubleshoot Microsoft Defender Advanced Threat Protection onboarding issues.

Offboard devices using a local script

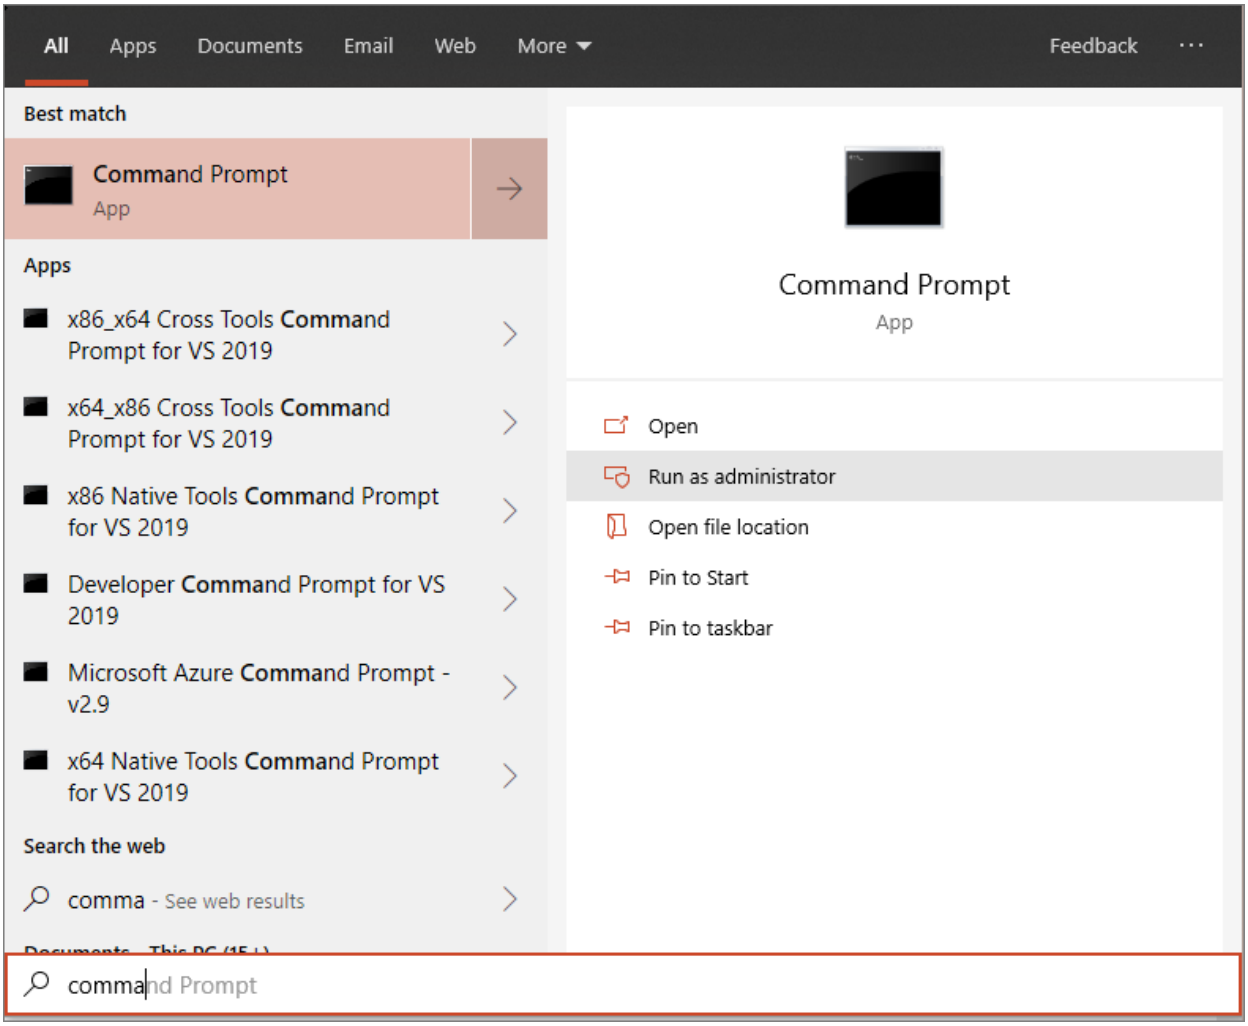
For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to an device will be rejected. When downloading an offboarding package you will be notified of the packages expiry date and it will also be included in the package name.

> **NOTE**
> Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this will cause unpredictable collisions.

1. Get the offboarding package from Microsoft Compliance center
2. In the navigation pane, select **Settings** > **Device offboarding**.
3. In the **Deployment method** field, select **Local Script**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the devices. You

should have a file named *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd*.

6. Open an elevated command-line prompt on the device and run the script:
7. Go to **Start** and type **cmd**.
8. Right-click **Command prompt** and select **Run as administrator**.



9. Type the location of the script file. If you copied the file to the desktop, type:
%userprofile%\Desktop\WindowsDefenderATPOffboardingScript_valid_until_YYYY-MM-DD.cmd
10. Press the **Enter** key or click **OK**.

> **IMPORTANT**
> Offboarding causes the device to stop sending sensor data to the portal.

Monitor device configuration

You can follow the different verification steps in the [Troubleshoot onboarding issues] ((https://docs.microsoft.com/windows/security/threat-protection/microsoft-defender-atp/troubleshoot-onboarding) to verify that the script completed successfully and the agent is running.

Monitoring can also be done directly on the portal, or by using the different deployment tools.

Monitor devices using the portal

1. Go to Microsoft 365 Compliance center.
2. Choose **Settings** > **Device onboarding** > **Devices**.

3. Verify that devices are appearing.

Onboard non-persistent virtual desktop infrastructure (VDI) devices

11/2/2020 • 3 minutes to read • Edit Online

Applies to:

- Microsoft 365 Endpoint data loss prevention (DLP)
- Virtual desktop infrastructure (VDI) devices

> **WARNING**
> Microsoft 365 Endpoint data loss prevention support for Windows Virtual Desktop supports single session scenarios. Multi-session scenarios on Windows Virtual Desktop are currently not supported.

Onboard VDI devices

Microsoft 365 Endpoint data loss prevention supports non-persistent VDI session onboarding.

> **NOTE**
> To onboard non-persistent VDI sessions, VDI devices must be on Windows 10 1809 or higher.

There might be associated challenges when onboarding VDIs. The following are typical challenges for this scenario:

- Instant early onboarding of a short-lived sessions, which must be onboarded to Microsoft 365 Endpoint data loss prevention prior to the actual provisioning.
- The device name is typically reused for new sessions.

VDI devices can appear in the Microsoft 365 Compliance center as either:

- Single entry for each device.
  Note that in this case, the *same* device name must be configured when the session is created, for example using an unattended answer file.
- Multiple entries for each device - one for each session.

The following steps will guide you through onboarding VDI devices and will highlight steps for single and multiple entries.

> **WARNING**
> For environments where there are low resource configurations, the VDI boot procedure might slow the Microsoft 365 Endpoint data loss prevention onboarding.

1. Open the VDI configuration package .zip file (*DeviceCompliancePackage.zip*) that you downloaded from the service onboarding wizard.
2. In the navigation pane, select **Settings** > **Device onboarding** > **Onboarding**.

3. In the **Deployment method** field, select **VDI onboarding scripts for non-persistent endpoints**.
4. Click **Download package** and save the .zip file.
5. Copy the files from the DeviceCompliancePackage folder extracted from the .zip file into the `golden/master` image under the path `C:\WINDOWS\System32\GroupPolicy\Machine\Scripts\Startup`.
6. If you are not implementing a single entry for each device, copy DeviceComplianceOnboardingScript.cmd.
7. If you are implementing a single entry for each device, copy both Onboard-NonPersistentMachine.ps1 and DeviceComplianceOnboardingScript.cmd.

   > **NOTE**
   > If you don't see the `C:\WINDOWS\System32\GroupPolicy\Machine\Scripts\Startup` folder, it might be hidden. You'll need to choose the **Show hidden files and folders** option from File Explorer.

8. Open a Local Group Policy Editor window and navigate to **Computer Configuration** > **Windows Settings** > **Scripts** > **Startup**.

   > **NOTE**
   > Domain Group Policy may also be used for onboarding non-persistent VDI devices.

9. Depending on the method you'd like to implement, follow the appropriate steps:

   For single entry for each device

   Select the **PowerShell Scripts** tab, then click **Add** (Windows Explorer will open directly in the path where you copied the onboarding script earlier). Navigate to onboarding PowerShell script `Onboard-NonPersistentMachine.ps1`.

   For multiple entries for each device:

   Select the **Scripts** tab, then click **Add** (Windows Explorer will open directly in the path where you copied the onboarding script earlier). Navigate to the onboarding bash script `DeviceComplianceOnboardingScript.cmd`.

10. Test your solution:
    a. Create a pool with one device.
    b. Logon to device.
    c. Logoff from device.
    d. Logon to device with another user.
    e. **For single entry for each device**: Check only one entry in Microsoft Defender Security Center.
    For multiple entries for each device: Check multiple entries in Microsoft Defender Security Center.
11. Click **Devices list** on the Navigation pane.
12. Use the search function by entering the device name and select **Device** as search type.

Updating non-persistent virtual desktop infrastructure (VDI) images

As a best practice, we recommend using offline servicing tools to patch golden/master images.
For example, you can use the below commands to install an update while the image remains offline:

```
DISM /Mount-image /ImageFile:"D:\Win10-1909.vhdx" /index:1 /MountDir:"C:\Temp\OfflineServicing"
DISM /Image:"C:\Temp\OfflineServicing" /Add-Package /Packagepath:"C:\temp\patch\windows10.0-kb4541338-x64.msu"
DISM /Unmount-Image /MountDir:"C:\Temp\OfflineServicing" /commit
```

For more information on DISM commands and offline servicing, please refer to the articles below:

- Modify a Windows image using DISM
- DISM Image Management Command-Line Options
- Reduce the Size of the Component Store in an Offline Windows Image

If offline servicing is not a viable option for your non-persistent VDI environment, the following steps should be taken to ensure consistency and sensor health:

1. After booting the master image for online servicing or patching, run an offboarding script to turn off the Microsoft 365 Endpoint data loss prevention sensor. For more information, see Offboard devices using a local script.
2. Ensure the sensor is stopped by running the command below in a CMD window:

   ```
   sc query sense
   ```

3. Service the image as needed.
4. Run the below commands using PsExec.exe (which can be downloaded from https://download.sysinternals.com/files/PSTools.zip) to cleanup the cyber folder contents that the sensor may have accumulated since boot:

   ```
   PsExec.exe -s cmd.exe
   cd "C:\ProgramData\Microsoft\Windows Defender Advanced Threat Protection\Cyber"
   del *.* /f /s /q
   REG DELETE “HKLM\SOFTWARE\Microsoft\Windows Advanced Threat Protection" /v senseGuid /f
   exit
   ```

5. Re-seal the golden/master image as you normally would.

Data loss prevention and Microsoft Teams

2/18/2021 • 6 minutes to read • Edit Online

> **NOTE**
> Data loss prevention capabilities were recently added to Microsoft Teams chat and channel messages for users licensed for Office 365 E5/A5, Microsoft 365 E5/A5, Microsoft 365 Information Protection and Governance or Office 365 Advanced Compliance. Office 365 and Microsoft 365 E3 include DLP protection for SharePoint Online, OneDrive, and Exchange Online. This also includes files that are shared through Teams because Teams uses SharePoint Online and OneDrive to share files. Support for DLP protection in Teams Chat requires E5. To learn more about licensing requirements, see Microsoft 365 Tenant-Level Services Licensing Guidance.

> **IMPORTANT**
> DLP for Teams is only supported when the user has a mailbox that is in Exchange Online

Overview of DLP for Microsoft Teams

Recently, data loss prevention (DLP) capabilities were extended to include Microsoft Teams chat and channel messages, **including private channel messages**.

If your organization has DLP, you can now define policies that prevent people from sharing sensitive information in a Microsoft Teams channel or chat session. Here are some examples of how this protection works:

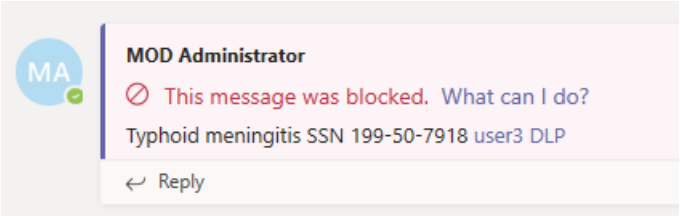
- **Example 1: Protecting sensitive information in messages**. Suppose that someone attempts to share sensitive information in a Teams chat or channel with guests (external users). If you have a DLP policy defined to prevent this, messages with sensitive information that are sent to external users are deleted. This happens automatically, and within seconds, according to how your DLP policy is configured.

  > **NOTE**
  > DLP for Microsoft Teams blocks sensitive content when shared with Microsoft Teams users who have:
  > - guest access in teams and channels; or
  > - external access in meetings and chat sessions.
  >
  > DLP for external chat sessions will only work if both the sender and the receiver are in Teams Only mode and using Microsoft Teams native federation. DLP for Teams does not block messages in interop with Skype for Business or non-native federated chat sessions.

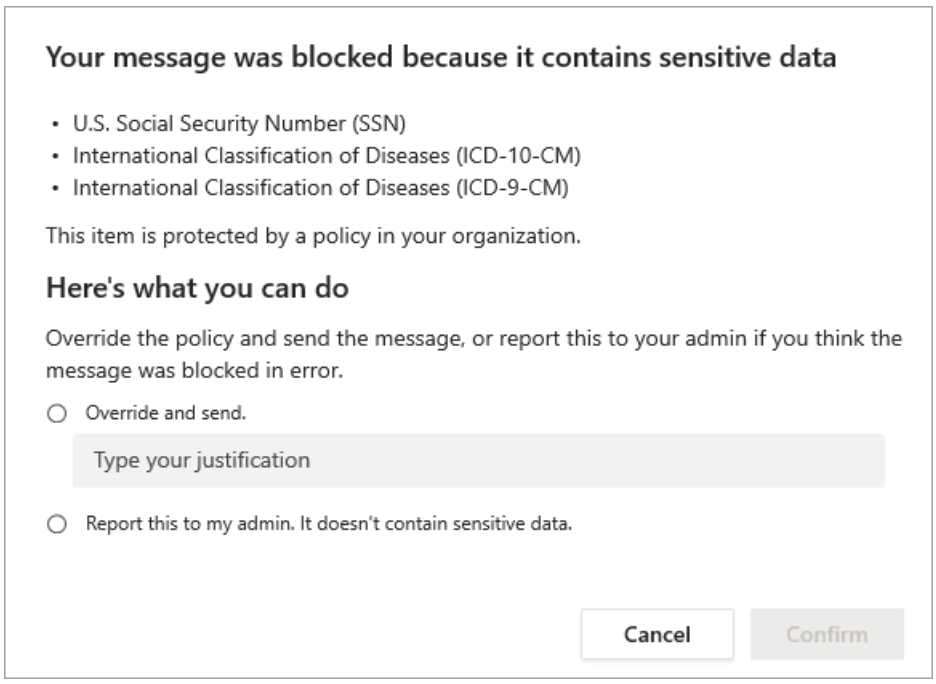
- **Example 2: Protecting sensitive information in documents**. Suppose that someone attempts to share a document with guests in a Microsoft Teams channel or chat, and the document contains sensitive information. If you have a DLP policy defined to prevent this, the document won't open for those users. Note that in this case, your DLP policy must include SharePoint and OneDrive in order for protection to be in place. (This is an example of DLP for SharePoint that shows up in Microsoft Teams, and therefore requires that users are licensed for Office 365 DLP (included in Office 365 E3), but does not require users to be licensed for Office 365 Advanced Compliance.)

Policy tips help educate users

Similar to how DLP works in Exchange, Outlook, Outlook on the web, SharePoint Online, OneDrive for Business sites, and Office desktop clients, policy tips appear when an action conflicts with a DLP policy. Here's an example of a policy tip:

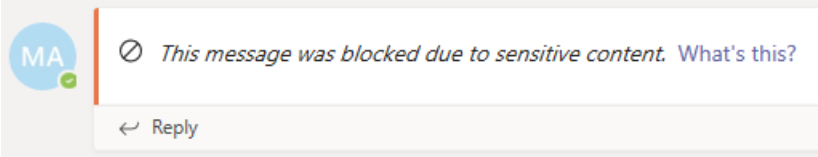


In this case, the sender attempted to share a social security number in a Microsoft Teams channel. The **What can I do?** link opens a dialog box that provides options for the sender to resolve the issue. Notice that in this case, the sender can opt to override the policy, or notify an admin to review and resolve it.



In your organization, you can choose to allow users to override a DLP policy. And, when you configure your DLP policies, you can use the default policy tips, or customize policy tips for your organization.

Returning to our example, where a sender shared a social security number in a Teams channel, here's what the recipient saw:

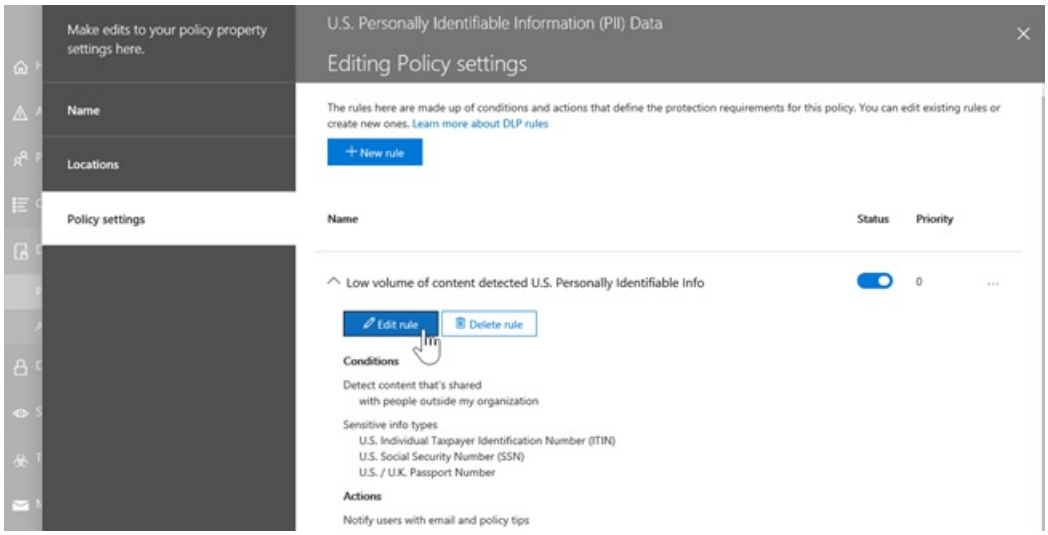


The **What's this?** link opens an article about DLP policies, which helps explain why the message was blocked.

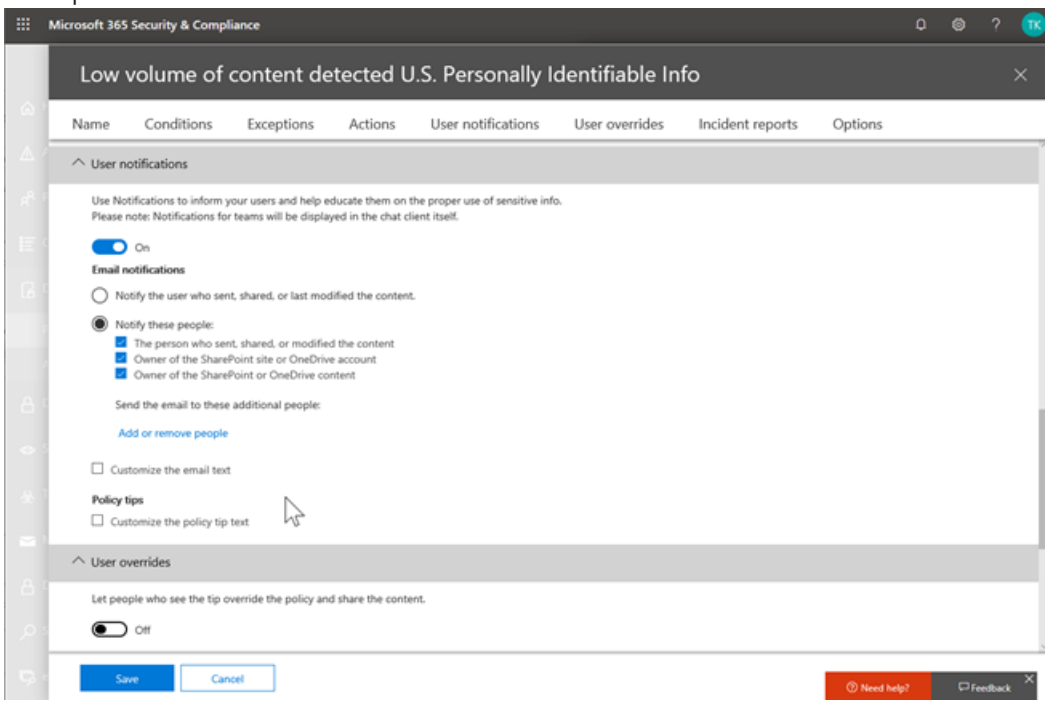
To customize policy tips

To perform this task, you must be assigned a role that has permissions to edit DLP policies. To learn more, see Permissions.

1. Go to the Security & Compliance Center (https://protection.office.com) and sign in.
2. Choose **Data loss prevention** > **Policy**.
3. Select a policy, and next to **Policy settings**, choose **Edit**.
4. Either create a new rule, or edit an existing rule for the policy.



5. On the **User notifications** tab, select **Customize the email text** and/or **Customize the policy tip text** options.



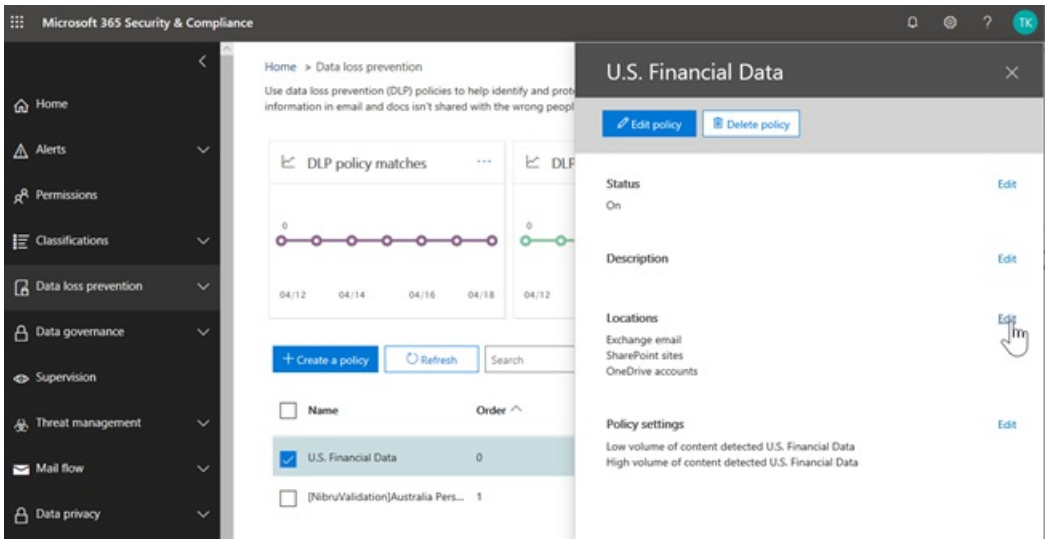
6. Specify the text you want to use for email notifications and/or policy tips, and then choose **Save**.
7. On the **Policy settings** tab, choose **Save**.

Allow approximately one hour for your changes to work their way through your data center and sync to user accounts.

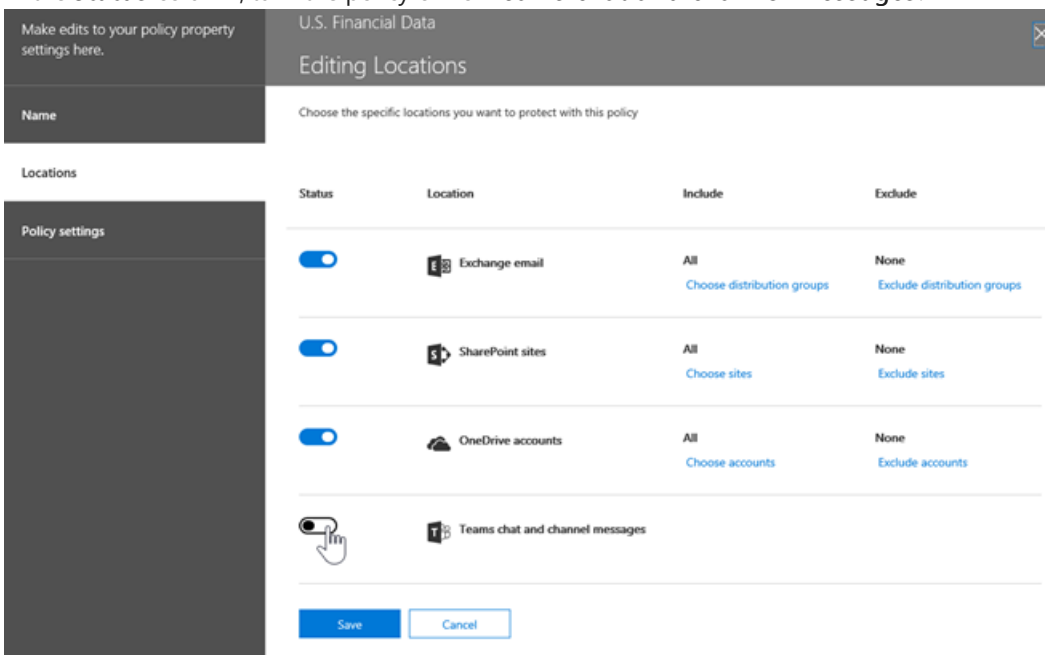
Add Microsoft Teams as a location to existing DLP policies

To perform this task, you must be assigned a role that has permissions to edit DLP policies. To learn more, see Permissions.

1. Go to the Security & Compliance Center (https://protection.office.com) and sign in.
2. Choose **Data loss prevention** > **Policy**.
3. Select a policy, and look at the values under **Locations**. If you see **Teams chat and channel messages**, you're all set. If you don't, click **Edit**.



4. In the **Status** column, turn the policy on for **Teams chat and channel messages**.



5. On the **Choose locations** tab, keep the default setting of all accounts, or select **Let me choose specific locations**. You can specify:

   a. up to 1000 individual accounts to include or exclude
   b. distribution lists and security groups to include or exclude. **This is a public preview feature.**

6. Then choose **Next**.

7. Click **Save**.

Allow approximately one hour for your changes to work their way through your data center and sync to user accounts.

Define a new DLP policy for Microsoft Teams

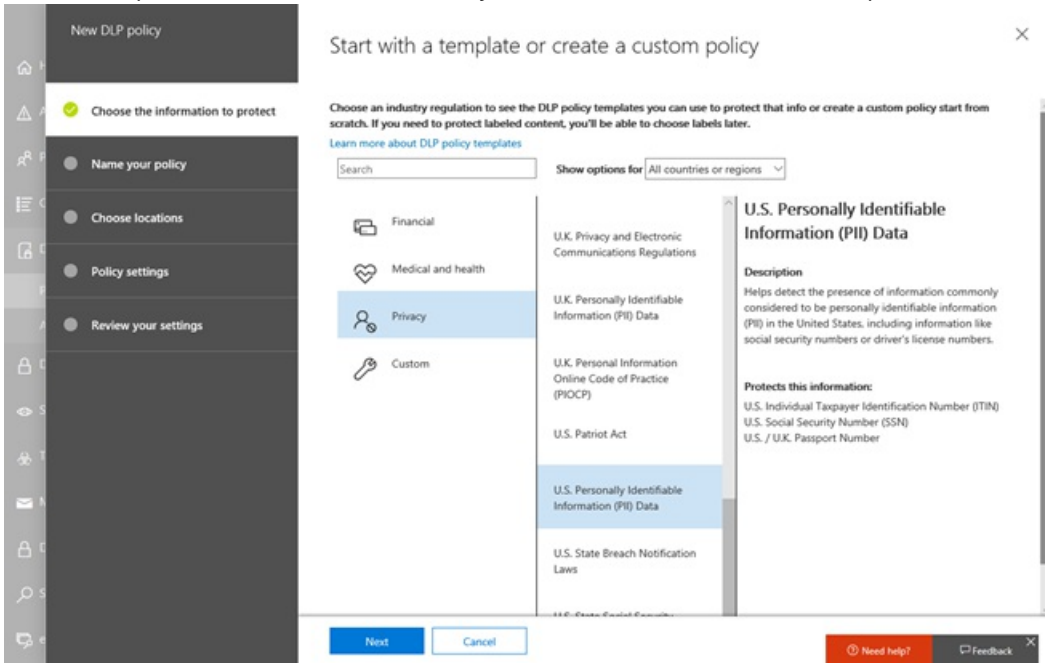
To perform this task, you must be assigned a role that has permissions to edit DLP policies. To learn more, see Permissions.

1. Go to the Security & Compliance Center (https://protection.office.com) and sign in.

2. Choose **Data loss prevention** > **Policy** > **+ Create a policy**.

3. Choose a template, and then choose **Next**.

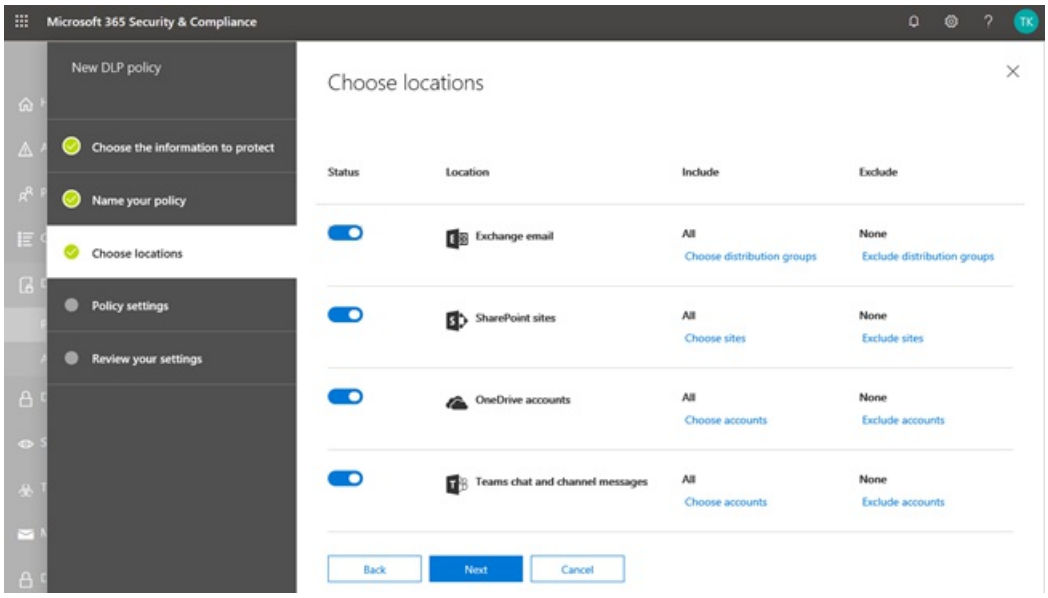
In our example, we chose the U.S. Personally Identifiable Information Data template.



4. On the **Name your policy** tab, specify a name and description for the policy, and then choose **Next**.

5. On the **Choose locations** tab, keep the default setting of all accounts, or select **Let me choose specific locations**. You can specify:

   a. up to 1000 individual accounts to include or exclude
   b. distribution lists and security groups to include or exclude. **This is a public preview feature.**

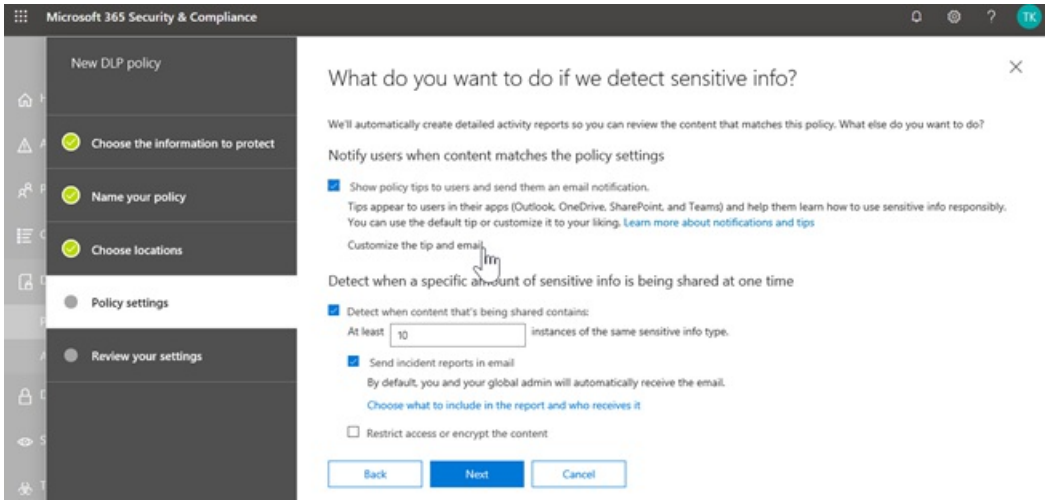


> **NOTE**
> If you want to make sure documents that contain sensitive information are not shared inappropriately in Teams, make sure **SharePoint sites** and **OneDrive accounts** are turned on, along with **Teams chat and channel messages**.

6. On the **Policy settings** tab, under **Customize the type of content you want to protect**, keep the default simple settings, or choose **Use advanced settings**, and then choose **Next**. If you choose advanced settings, you can create or edit rules for your policy. (To get help with this, see Simple settings vs. advanced settings.)

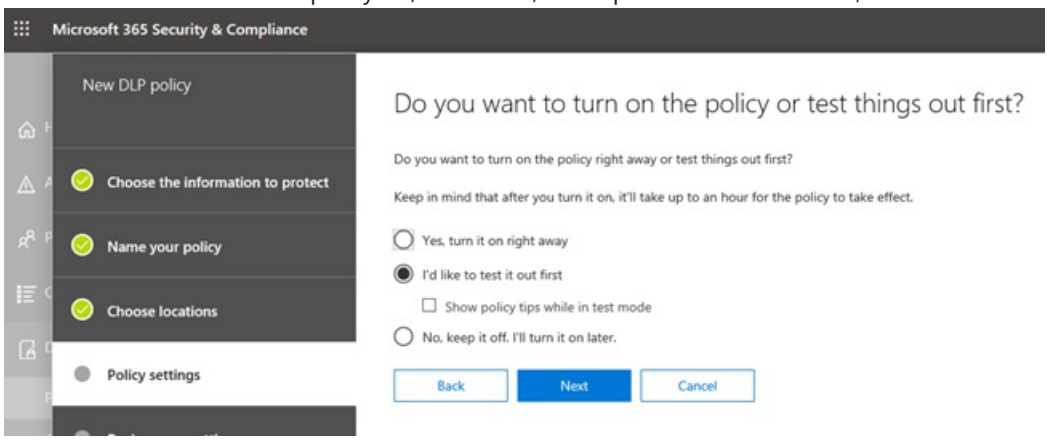
7. On the **Policy settings** tab, under **What do you want to do if we detect sensitive info?**, review the

settings. (Here's where you can choose to keep default policy tips and email notifications, or customize them.)



When you're finished reviewing or editing settings, choose **Next**.

8. On the **Policy settings** tab, under **Do you want to turn on the policy or test things out first?**, choose whether to turn the policy on, test it first, or keep it turned off for now, and then choose **Next**.



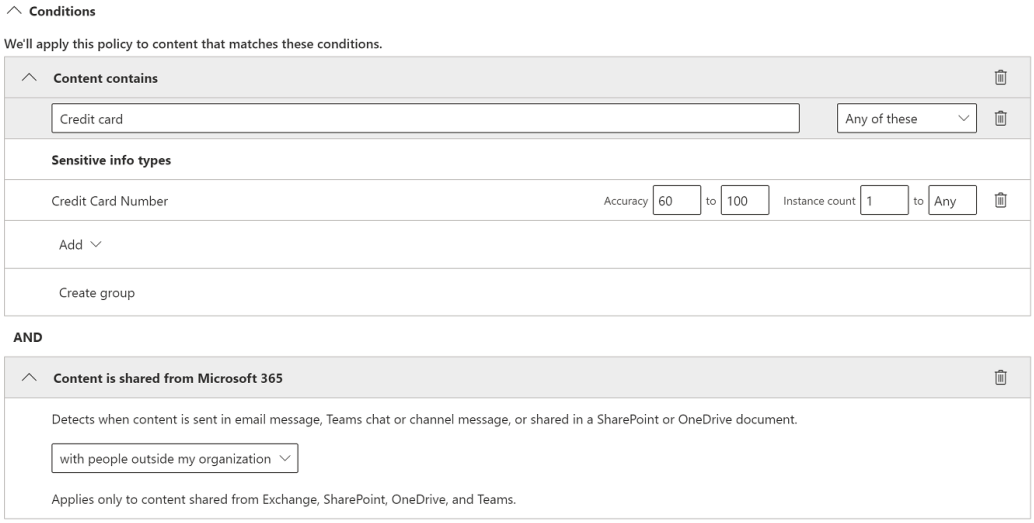
9. On the **Review your settings** tab, review the settings for your new policy. Choose **Edit** to make changes. When you're finished, choose **Create**.

Allow approximately one hour for your new policy to work its way through your data center and sync to user accounts.

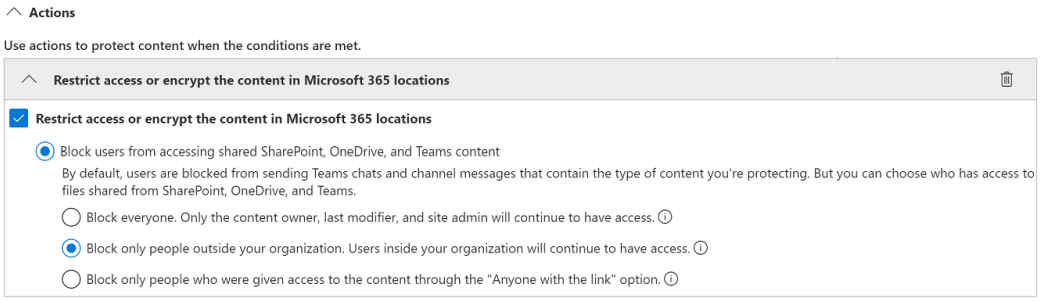
Prevent external access to sensitive documents

To ensure that SharePoint documents that contain sensitive information cannot be accessed by external guests either from SharePoint or Teams by default, select the following:

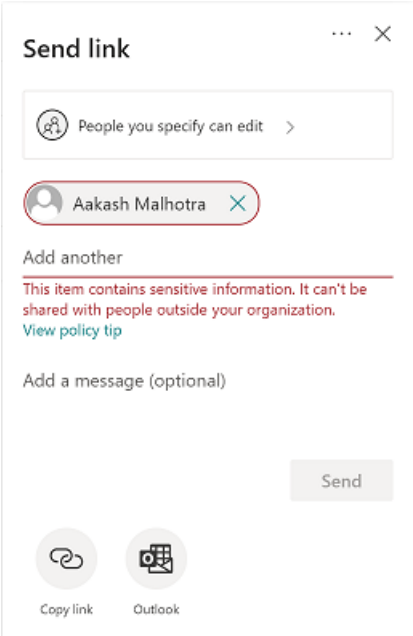
- You can ensure that documents are protected until DLP scans and marks them as safe to share by marking new files as sensitive by default
- Recommended DLP policy structure
  - **Conditions**
    - Content contains any of these sensitive information types: [Select all that applies]
    - Content is shared from Microsoft 365 with people outside my organization



- **Actions**
  - Restrict access to the content for external users
  - Notify users with email and policy tips
  - Send incident reports to the Administrator



DLP policy in action when attempting to share a document in SharePoint that contains sensitive information with an external guest:



DLP policy in action when guest attempts to open a document in Teams with block external:

Send email notifications and show policy tips for DLP policies

Using Endpoint data loss prevention

2/18/2021 • 7 minutes to read • Edit Online

This article walks you through three scenarios where you create and modify a DLP policy that uses devices as a location.

DLP settings

Before you get started you should set up your DLP settings which are applied to all DLP policies for devices. You must configure these if you intend to create policies that enforce:

- cloud egress restrictions
- unallowed apps restrictions

Or

- If you want to exclude noisy file paths from monitoring

File path exclusions

You may want to exclude certain paths from DLP monitoring, DLP alerting, and DLP policy enforcement on your devices because they are too noisy or don't contain files you are interested in. Files in those locations will not be audited and any files that are created or modified in those locations will not be subject to DLP policy enforcement. You can configure path exclusions in DLP settings.

You can use this logic to construct your exclusion paths:

- Valid file path that ends with '\', which means only files directly under folder.
  For example: C:\Temp\
- Valid file path that ends with '*', which means only files under sub-folders, besides the files directly under the folder.
  For example: C:\Temp*
- Valid file path that ends without '\' or '*', which means all files directly under folder and all sub-folders.
  For example: C:\Temp
- A path with wildcard between '\' from each side.
  For example: C:\Users*\Desktop\
- A path with wildcard between '\' from each side and with '(number)' to give exact number of subfolders.
  For example: C:\Users*(1)\Downloads\
- A path with SYSTEM environment variables.
  For example: %SystemDrive%\Test*
- A mix of all the above.

For example: %SystemDrive%\Users*\Documents*(2)\Sub\

Unallowed apps

When a policy's **Access by unallowed apps and browsers** setting is turned on and users attempt to use these apps to access a protected file, the activity will be allowed, blocked, or blocked but users can override the restriction. All activity is audited and available to review in activity explorer.

> **IMPORTANT**
> Do not include the path to the executable, but only the executable name (such as browser.exe).

Browser and domain restrictions

Restrict sensitive files that match your policies from being shared with unrestricted cloud service domains.

Service domains

You can control whether sensitive files protected by your policies can be uploaded to specific service domains from Microsoft Edge.

If the list mode is set to **Block**, then user will not be able to upload sensitive items to those domains. When an upload action is blocked because an item matches a DLP policy, DLP will either generate a warning or block the upload of the sensitive item.

If the list mode is set to **Allow**, then users will be able to upload sensitive items ***only*** to those domains, and upload access to all other domains is not allowed.

Unallowed browsers

You add browsers, identified by their executable names, that will be blocked from accessing files that match the conditions of an enforced a DLP policy where the upload to cloud services restriction is set to block or block override. When these browsers are blocked from accessing a file, the end users will see a toast notification asking them to open the file through Edge Chromium.

Business justification in policy tips

You can control how users interact with the business justification option in DLP policy tip notifications. This option appears when users perform an activity that's protected by the **Block with override** setting in a DLP policy. You can choose from one the following options:

- By default, users can select either a built-in justification, or enter their own text.
- Users can only select a built-in justification.
- Users can only enter their own justification.

Tying DLP settings together

With Endpoint DLP and Edge Chromium Web browser, you can restrict unintentional sharing of sensitive items to unallowed cloud apps and services. Edge Chromium understands when an item is restricted by an Endpoint DLP policy and enforces access restrictions.

When you use Endpoint DLP as a location in a properly configured DLP policy and the Edge Chromium browser, the unallowed browsers that you've defined in these settings will be prevented from accessing the sensitive items that match your DLP policy controls. Instead, users will be redirected to use Edge Chromium and Edge Chromium, with its understanding of DLP imposed restrictions, can block or restrict activities when the conditions in the DLP policy are met.

To use this restriction you'll need to configure three important pieces:

1. Specify the places – services, domains, IP addresses – that you want to prevent sensitive items from being shared to.

2. Add the browsers that aren't allowed to access certain sensitive items when a DLP policy match occurs.
3. Configure DLP policies to define the kinds of sensitive items for which upload should be restricted to these places by turning on **Upload to cloud services** and **Access from unallowed browser**.

You can continue to add new services, apps, and policies to extend and augment your restrictions to meet your business needs and protect sensitive data.

This configuration will help ensure your data remains safe while also avoiding unnecessary restrictions that prevent or restrict users from accessing and sharing non-sensitive items.

Endpoint DLP policy scenarios

To help familiarize you with Endpoint DLP features and how they surface in DLP policies, we've put together some scenarios for you to follow. All the Endpoint DLP content will be folded in to the main DLP content set when Endpoint DLP becomes generally available.

> **IMPORTANT**
> These Endpoint DLP scenarios are not the official procedures for creating and tuning DLP policies. Refer to the below topics when you need to work with DLP policies in general situations:
>
> - Overview of data loss prevention
> - Get started with the default DLP policy
> - Create a DLP policy from a template
> - Create, test, and tune a DLP policy

Scenario 1: Create a policy from a template, audit only

These scenarios require that you already have devices onboarded and reporting into Activity explorer. If you haven't onboarded devices yet, see Get started with Endpoint data loss prevention.

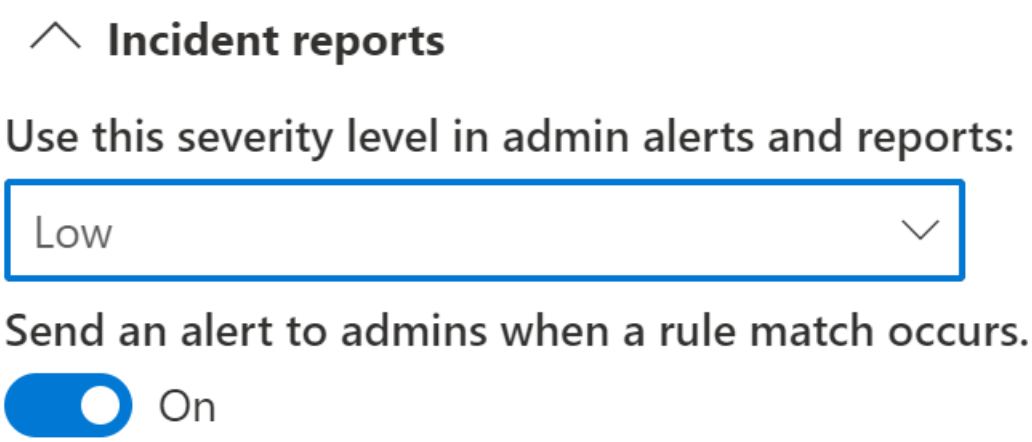
1. Open the Data loss prevention page.
2. Choose **Create policy**.
3. For this scenario, choose **Privacy**, then **U.S. Personally Identifiable Information (PII) Data** and choose **Next**.
4. Toggle the **Status** field to off for all locations except **Devices**. Choose **Next**.
5. Accept the default **Review and customize settings from the template** selection and choose **Next**.
6. Accept the default **Protection actions** values and choose **Next**.
7. Select **Audit or restrict activities on Windows devices** and leave the actions set to **Audit only**. Choose **Next**.
8. Accept the default **I'd like to test it out first** value and choose **Show policy tips while in test mode**. Choose **Next**.
9. Review your settings and choose **Submit**.
10. The new DLP policy will appear in the policy list.
11. Check Activity explorer for data from the monitored endpoints. Set the location filter for devices and add the policy, then filter by policy name to see the impact of this policy. See, Get started with activity explorer if needed.
12. Attempt to share a test that contains content that will trigger the U.S. Personally Identifiable Information

(PII) Data condition with someone outside your organization. This should trigger the policy.

13. Check Activity explorer for the event.

Scenario 2: Modify the existing policy, set an alert

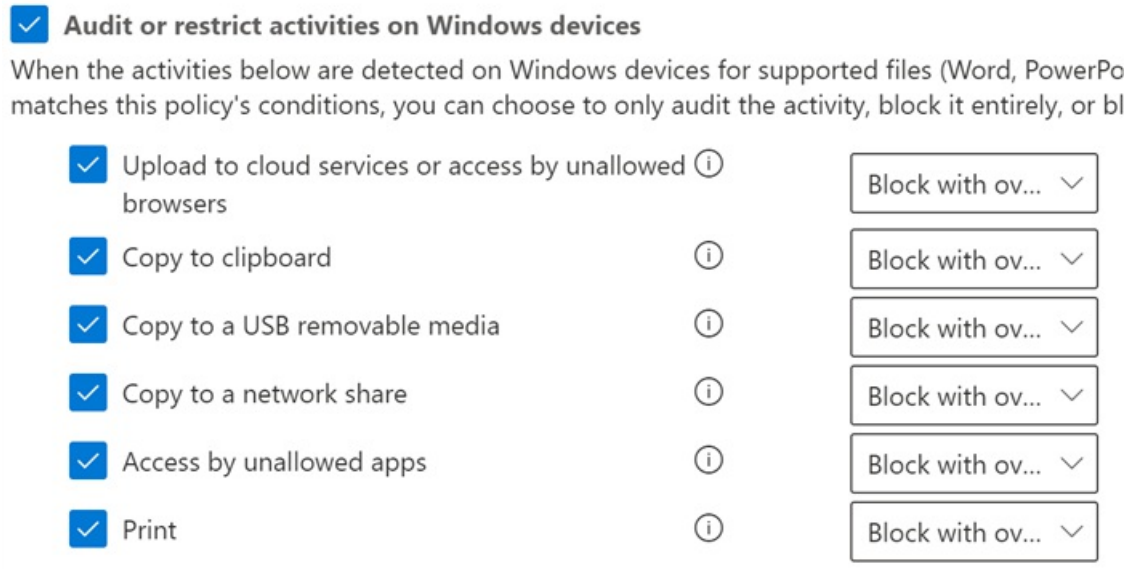
1. Open the Data loss prevention page.
2. Choose the **U.S. Personally Identifiable Information (PII) Data** policy that you created in scenario 1.
3. Choose **edit policy**.
4. Go to the **Advanced DLP rules** page and edit the **Low volume of content detected U.S. Personally Identifiable Inf**.
5. Scroll down to the **Incident reports** section and set **Send an alert to admins when a rule match occurs** to **On**. Email alerts will be automatically sent to the administrator and anyone else you add to the list of recipients.



6. For the purposes of this scenario, choose **Send alert every time an activity matches the rule**.
7. Choose **Save**.
8. Retain all your previous settings by choosing **Next** and then **Submit** the policy changes.
9. Attempt to share a test that contains content that will trigger the U.S. Personally Identifiable Information (PII) Data condition with someone outside your organization. This should trigger the policy.
10. Check Activity explorer for the event.

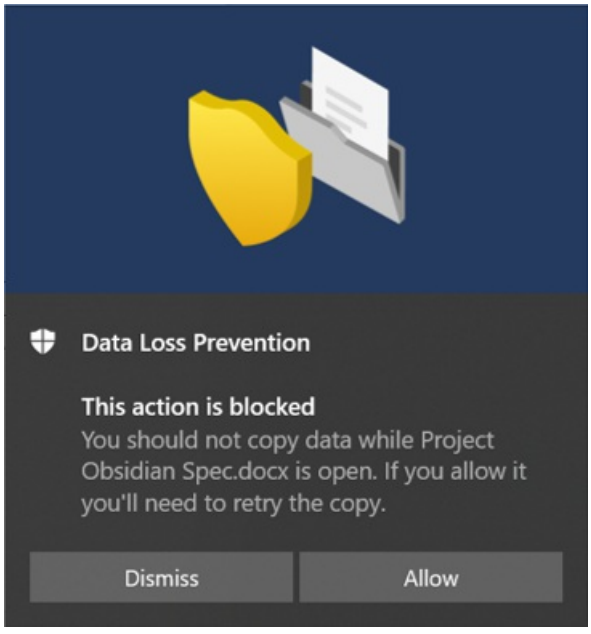
Scenario 3: Modify the existing policy, block the action with allow override

1. Open the Data loss prevention page.
2. Choose the **U.S. Personally Identifiable Information (PII) Data** policy that you created in scenario 1.
3. Choose **edit policy**.
4. Go to the **Advanced DLP rules** page and edit the **Low volume of content detected U.S. Personally Identifiable Inf**.
5. Scroll down to the **Audit or restrict activities on Windows device** section and for each activity set the corresponding action to **Block with override**.



6. Choose **Save**.
7. Repeat steps 4-7 for the **High volume of content detected U.S. Personally Identifiable Inf**.
8. Retain all your previous settings by choosing **Next** and then **Submit** the policy changes.
9. Attempt to share a test that contains content that will trigger the U.S. Personally Identifiable Information (PII) Data condition with someone outside your organization. This should trigger the policy.

   You'll see a popup like this on the client device:



10. Check Activity explorer for the event.

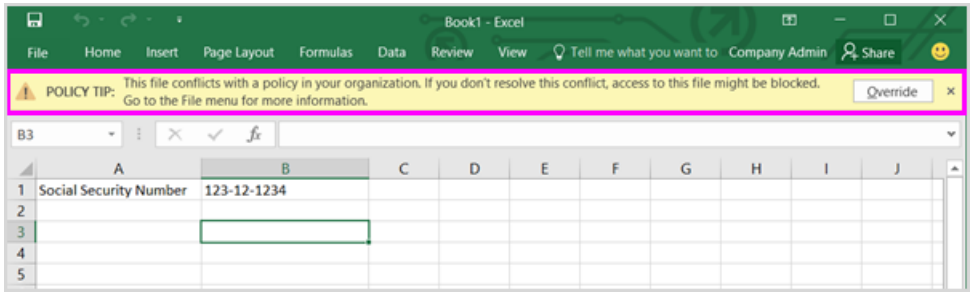
Send email notifications and show policy tips for DLP policies

2/18/2021 • 15 minutes to read • Edit Online

You can use a data loss prevention (DLP) policy to identify, monitor, and protect sensitive information across Office 365. You want people in your organization who work with this sensitive information to stay compliant with your DLP policies, but you don't want to block them unnecessarily from getting their work done. This is where email notifications and policy tips can help.



A policy tip is a notification or warning that appears when someone is working with content that conflicts with a DLP policy—for example, content like an Excel workbook on a OneDrive for Business site that contains personally identifiable information (PII) and is shared with an external user.

You can use email notifications and policy tips to increase awareness and help educate people about your organization's policies. You can also give people the option to override the policy, so that they're not blocked if they have a valid business need or if the policy is detecting a false positive.

In the Security & Compliance Center, when you create a DLP policy, you can configure the user notifications to:

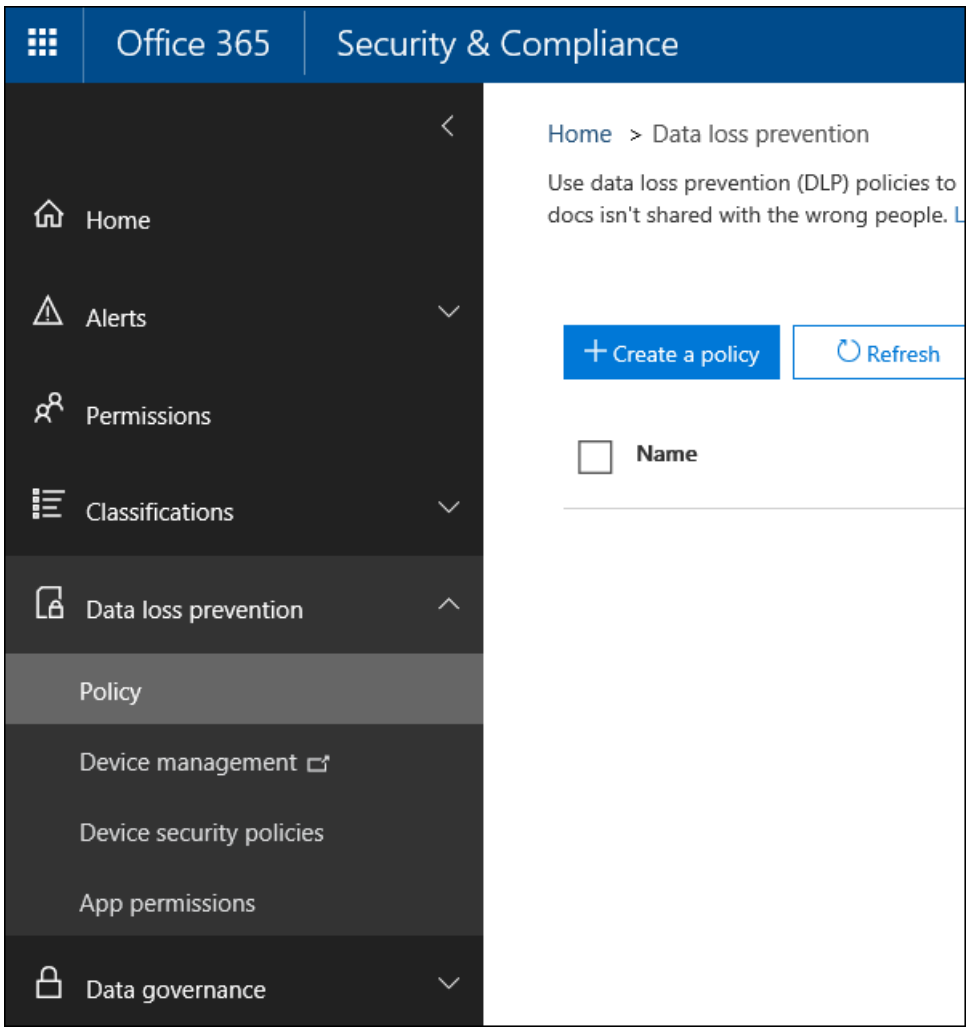
- Send an email notification to the people you choose that describes the issue.
- Display a policy tip for content that conflicts with the DLP policy:
  - For email in Outlook on the web and Outlook 2013 and later, the policy tip appears at the top of a message above the recipients while the message is being composed.
  - For documents in a OneDrive for Business account or SharePoint Online site, the policy tip is indicated by a warning icon that appears on the item. To view more information, you can select an item and then choose **Information** in the upper-right corner of the page to open the details pane.
  - For Excel, PowerPoint, and Word documents that are stored on a OneDrive for Business site or SharePoint Online site that's included in the DLP policy, the policy tip appears on the Message Bar and the Backstage view (**File** menu > **Info**).

Add user notifications to a DLP policy

When you create a DLP policy, you can enable **User notifications**. When user notifications are enabled, Microsoft 365 sends out both email notifications and policy tips. You can customize who notification emails are sent to, the email text and the policy tip text.

1. Go to https://protection.office.com.
2. Sign in using your work or school account. You're now in the Security & Compliance Center.

3. In the Security & Compliance Center > left navigation > **Data loss prevention** > **Policy** > **+ Create a policy**.



4. Choose the DLP policy template that protects the types of sensitive information that you need > **Next**.

   To start with an empty template, choose **Custom** > **Custom policy** > **Next**.

5. Name the policy > **Next**.

6. To choose the locations that you want the DLP policy to protect, do one of the following:

   - Choose **All locations in Office 365** > **Next**.
   - Choose **Let me choose specific locations** > **Next**.

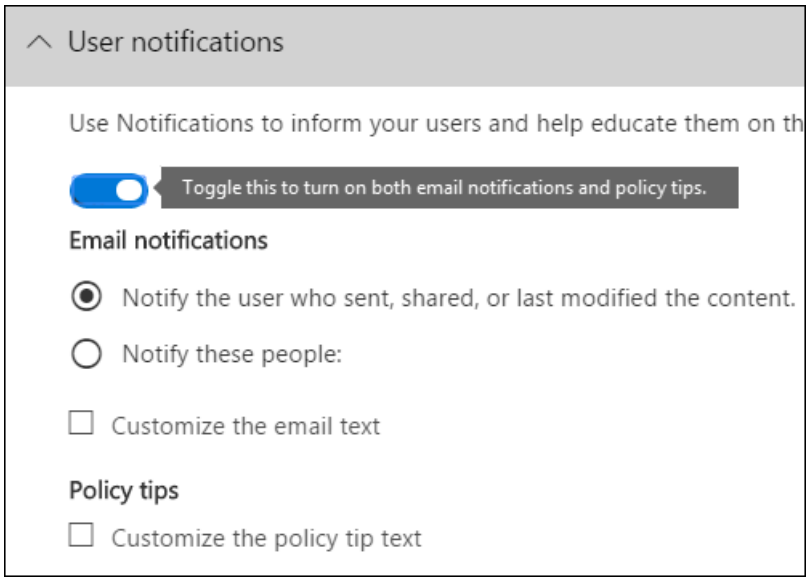
   To include or exclude an entire location such as all Exchange email or all OneDrive accounts, switch the **Status** of that location on or off.

   To include only specific SharePoint sites or OneDrive accounts, switch the **Status** to on, and then click the links under **Include** to choose specific sites or accounts.

7. Choose **Use advanced settings** > **Next**.

8. Choose **+ New rule**.

9. In the rule editor, under **User notifications**, switch the status on.



NOTE

DLP policies apply to all documents that match the policy, whether those documents are new or existing. However, an email notification is only generated when new content matches an existing DLP policy. Existing content is protected, but will not generate a user notification via email.

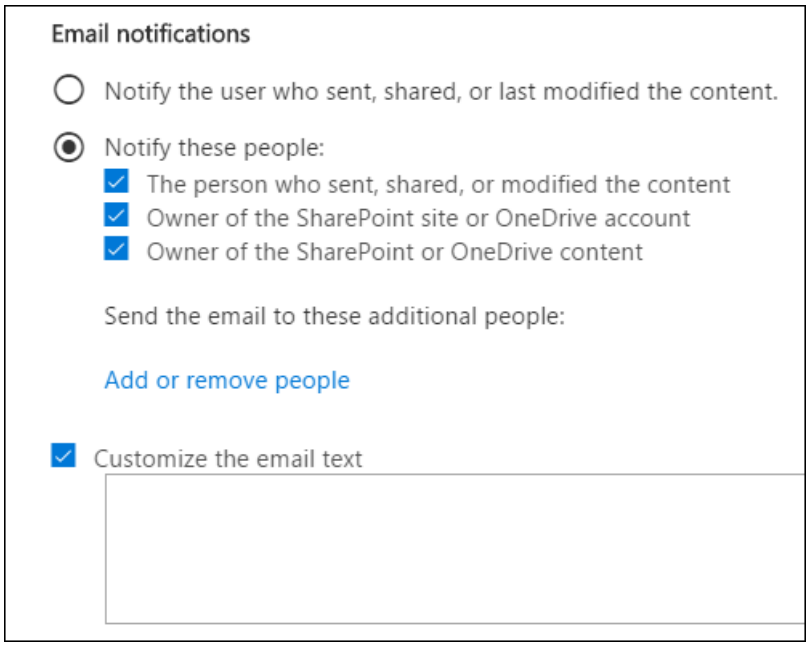
Options for configuring email notifications

For each rule in a DLP policy, you can:

- Send the notification to the people you choose. These people can include the owner of the content, the person who last modified the content, the owner of the site where the content is stored, or a specific user.
- Customize the text that's included in the notification by using HTML or tokens. See the section below for more information.

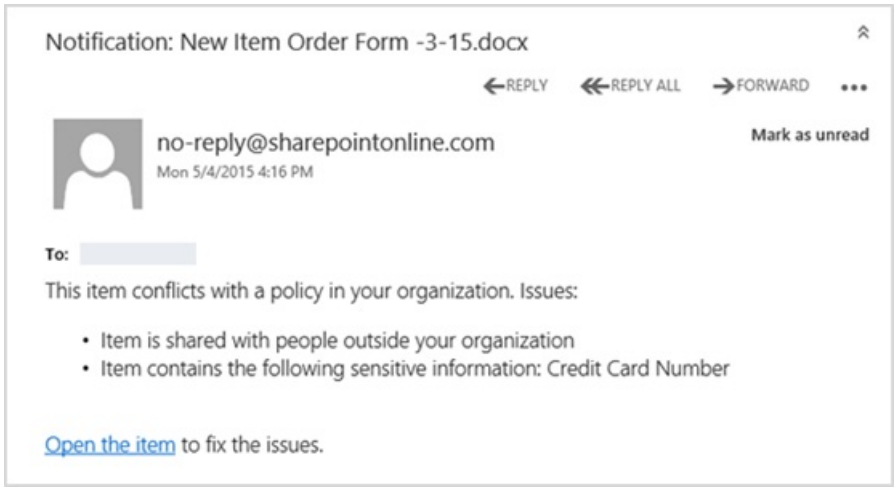
NOTE

Email notifications can be sent only to individual recipients—not groups or distribution lists. Only new content will trigger an email notification. Editing existing content will trigger policy tips, but not an email notification.



Default email notification

Notifications have a Subject line that begins with the action taken, such as "Notification", "Message Blocked" for email, or "Access Blocked" for documents. If the notification is about a document, the notification message body includes a link that takes you to the site where the document's stored and opens the policy tip for the document, where you can resolve any issues (see the section below about policy tips). If the notification is about a message, the notification includes as an attachment the message that matches a DLP policy.



By default, notifications display text similar to the following for an item on a site. The notification text is configured separately for each rule, so the text that's displayed differs depending on which rule is matched.

IF THE DLP POLICY RULE DOES THIS...	THEN THE DEFAULT NOTIFICATION FOR SHAREPOINT OR ONEDRIVE FOR BUSINESS DOCUMENTS SAYS THIS...	THEN THE DEFAULT NOTIFICATION FOR OUTLOOK MESSAGES SAYS THIS...
Sends a notification but doesn't allow override	This item conflicts with a policy in your organization.	Your email message conflicts with a policy in your organization.
Blocks access, sends a notification, and allows override	This item conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked.	Your email message conflicts with a policy in your organization. The message wasn't delivered to all recipients.
Blocks access and sends a notification	This item conflicts with a policy in your organization. Access to this item is blocked for everyone except its owner, last modifier, and the primary site collection administrator.	Your email message conflicts with a policy in your organization. The message wasn't delivered to all recipients.

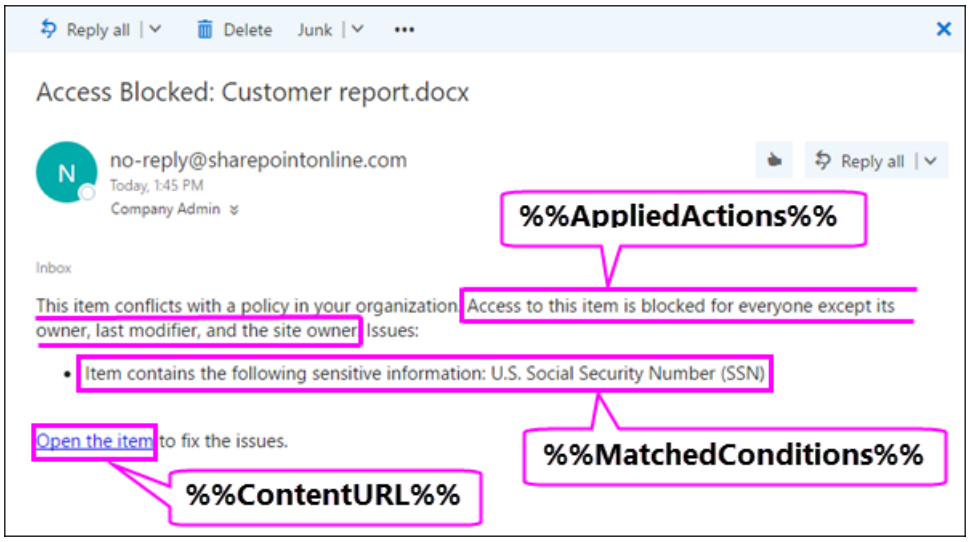
Custom email notification

You can create a custom email notification instead of sending the default email notification to your end users or admins. The custom email notification supports HTML and has a 5,000-character limit. You can use HTML to include images, formatting, and other branding in the notification.

You can also use the following tokens to help customize the email notification. These tokens are variables that are replaced by specific information in the notification that's sent.

TOKEN	DESCRIPTION
%%AppliedActions%%	The actions applied to the content.
%%ContentURL%%	The URL of the document on the SharePoint Online site or OneDrive for Business site.

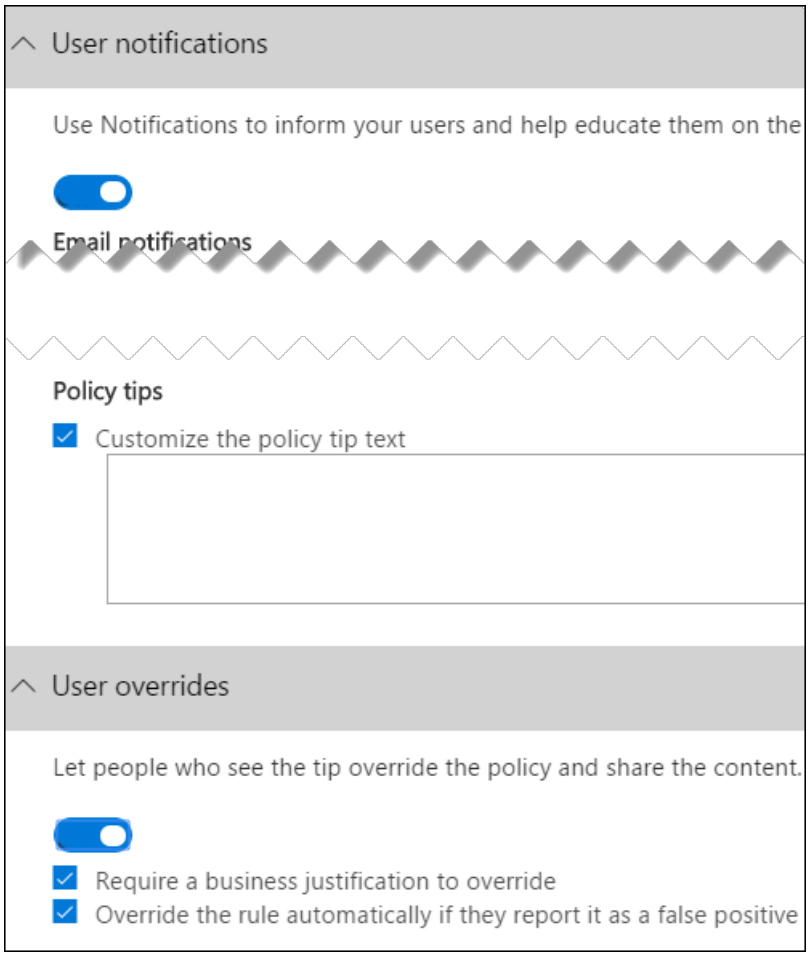
TOKEN	DESCRIPTION
%%MatchedConditions%%	The conditions that were matched by the content. Use this token to inform people of possible issues with the content.



Options for configuring policy tips

For each rule in a DLP policy, you can configure policy tips to:

- Simply notify the person that the content conflicts with a DLP policy, so that they can take action to resolve the conflict. You can use the default text (see the tables below) or enter custom text about your organization's specific policies.
- Allow the person to override the DLP policy. Optionally, you can:
  - Require the person to enter a business justification for overriding the policy. This information is logged and you can view it in the DLP reports in the **Reports** section of the Security & Compliance Center.
  - Allow the person to report a false positive and override the DLP policy. This information is also logged for reporting, so that you can use false positives to fine tune your rules.



For example, you may have a DLP policy applied to OneDrive for Business sites that detects personally identifiable information (PII), and this policy has three rules:

1. First rule: If fewer than five instances of this sensitive information are detected in a document, and the document is shared with people inside the organization, the **Send a notification** action displays a policy tip. For policy tips, no override options are necessary because this rule is simply notifying people and not blocking access.

2. Second rule: If greater than five instances of this sensitive information are detected in a document, and the document is shared with people inside the organization, the **Block access to content** action restricts the permissions for the file, and the **Send a notification** action allows people to override the actions in this rule by providing a business justification. Your organization's business sometimes requires internal people to share PII data, and you don't want your DLP policy to block this work.

3. Third rule: If greater than five instances of this sensitive information are detected in a document, and the document is shared with people outside the organization, the **Block access to content** action restricts the permissions for the file, and the **Send a notification** action does not allow people to override the actions in this rule because the information is shared externally. Under no circumstances should people in your organization be allowed to share PII data outside the organization.

Here are some fine points to understand about using a policy tip to override a rule:

- The option to override is per rule, and it overrides all of the actions in the rule (except sending a notification, which can't be overridden).

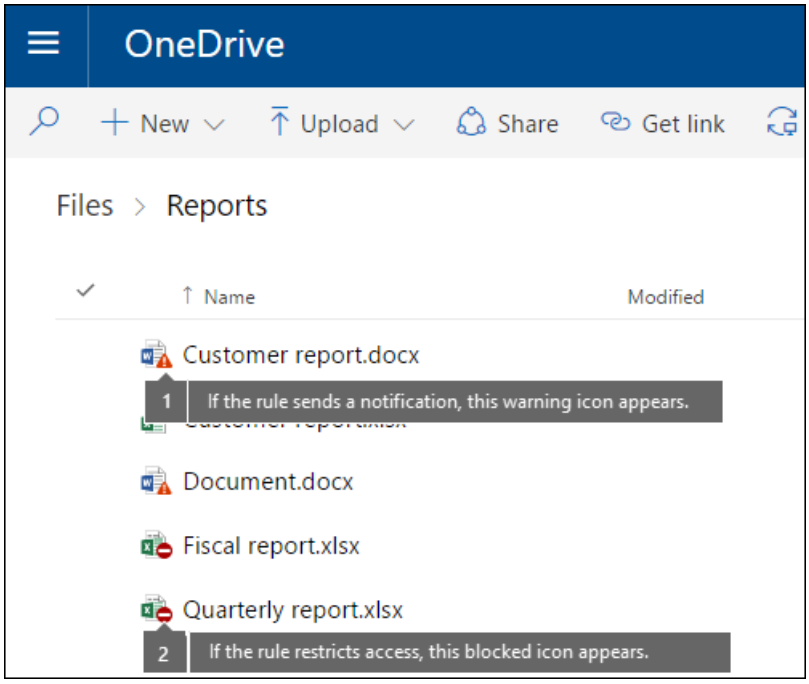
- It's possible for content to match several rules in a DLP policy, but only the policy tip from the most restrictive, highest-priority rule will be shown. For example, a policy tip from a rule that blocks access to content will be shown over a policy tip from a rule that simply sends a notification. This prevents people from seeing a cascade of policy tips.

- If the policy tips in the most restrictive rule allow people to override the rule, then overriding this rule also overrides any other rules that the content matched.

Policy tips on OneDrive for Business sites and SharePoint Online sites

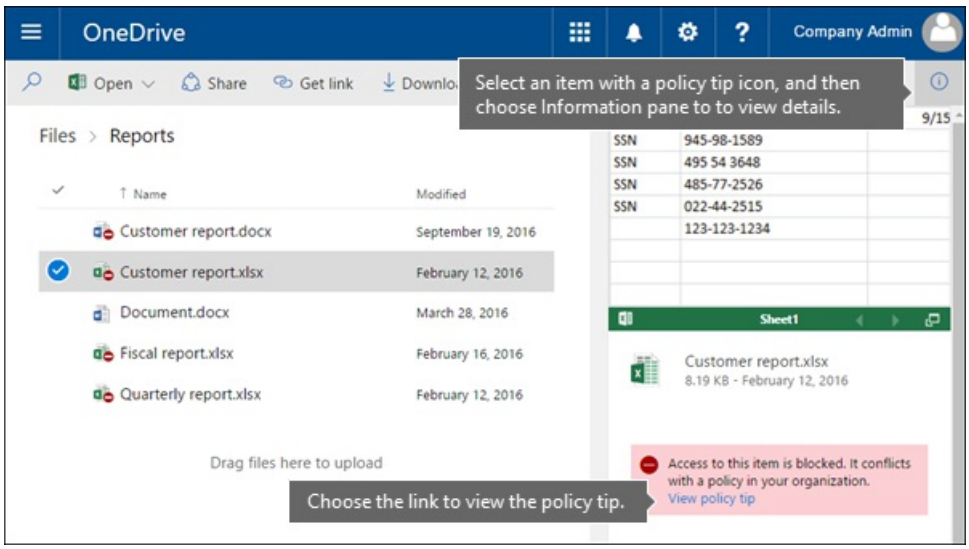
When a document on a OneDrive for Business site or SharePoint Online site matches a rule in a DLP policy, and that rule uses policy tips, the policy tips display special icons on the document:

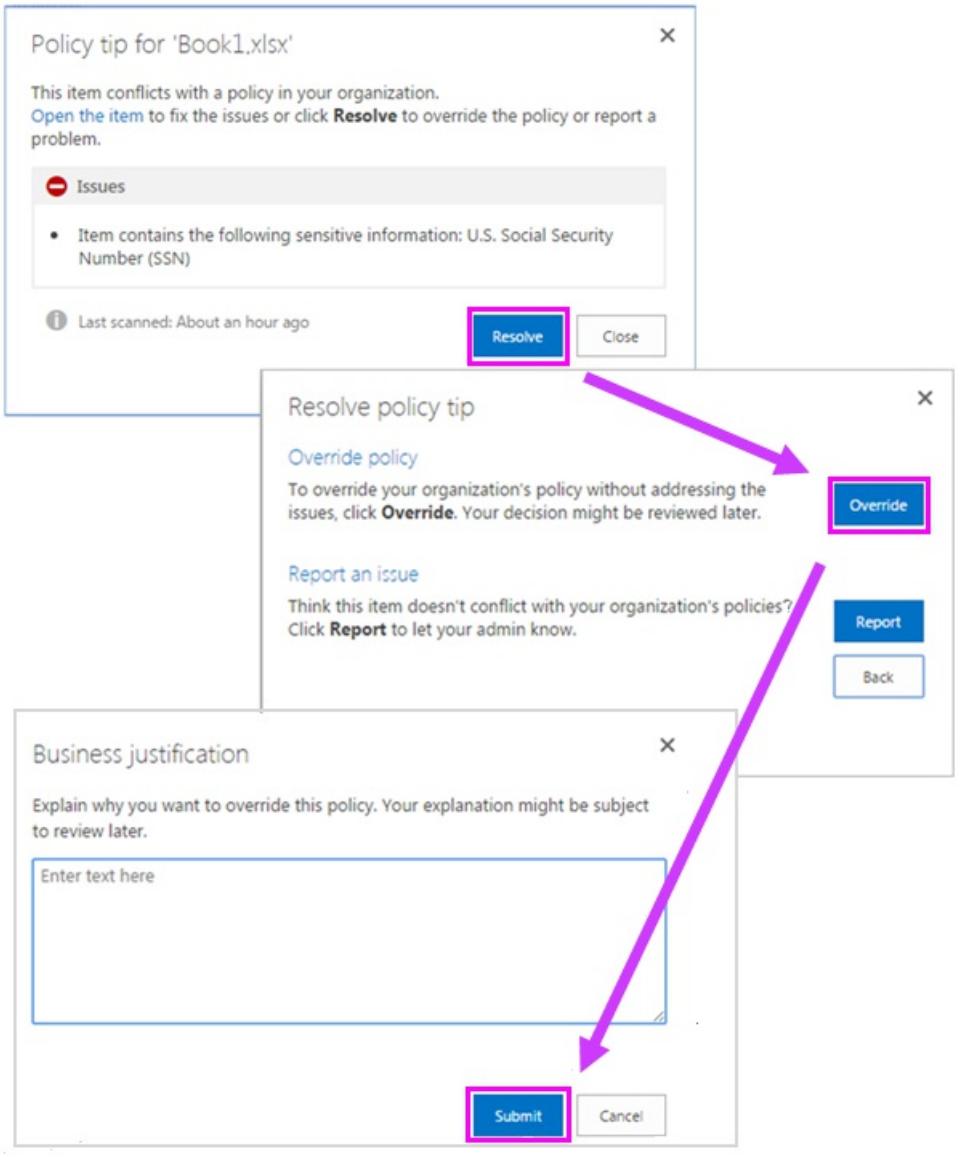
1. If the rule sends a notification about the file, the warning icon appears.
2. If the rule blocks access to the document, the blocked icon appears.



To take action on a document, you can select an item > choose **Information** in the upper-right corner of the page to open the details pane > **View policy tip**.

The policy tip lists the issues with the content, and if the policy tips are configured with these options, you can choose **Resolve**, and then **Override** the policy tip or **Report** a false positive.





DLP policies are synced to sites and contented is evaluated against them periodically and asynchronously, so there may be a short delay between the time you create the DLP policy and the time you begin to see policy tips. There may be a similar delay from when you resolve or override a policy tip to when the icon on the document on the site goes away.

Default text for policy tips on sites

By default, policy tips display text similar to the following for an item on a site. The notification text is configured separately for each rule, so the text that's displayed differs depending on which rule is matched.

IF THE DLP POLICY RULE DOES THIS...	THEN THE DEFAULT POLICY TIP SAYS THIS...
Sends a notification but doesn't allow override	This item conflicts with a policy in your organization.
Blocks access, sends a notification, and allows override	This item conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked.
Blocks access and sends a notification	This item conflicts with a policy in your organization. Access to this item is blocked for everyone except its owner, last modifier, and the primary site collection administrator.

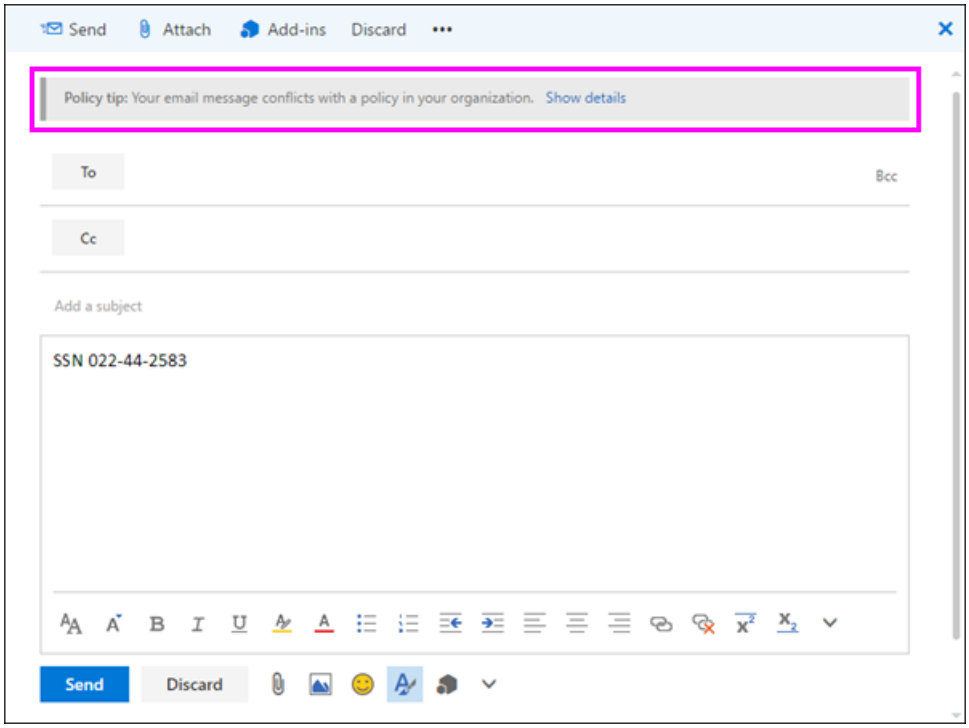
Custom text for policy tips on sites

You can customize the text for policy tips separately from the email notification. Unlike custom text for email

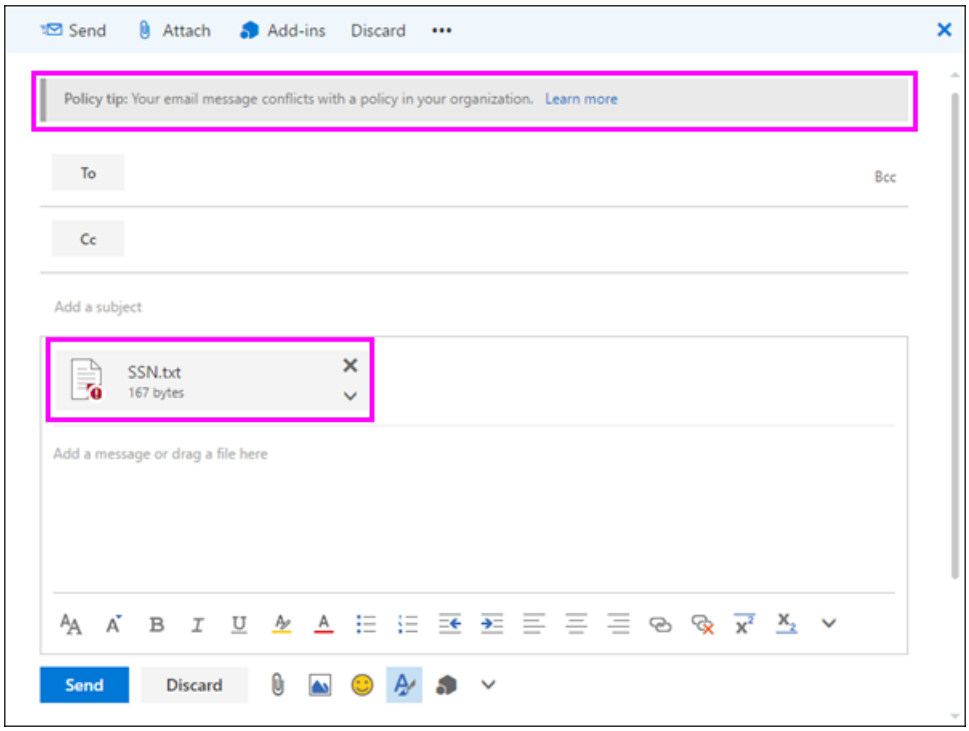
notifications (see above section), custom text for policy tips does not accept HTML or tokens. Instead, custom text for policy tips is plain text only with a 256-character limit.

Policy tips in Outlook on the web and Outlook 2013 and later

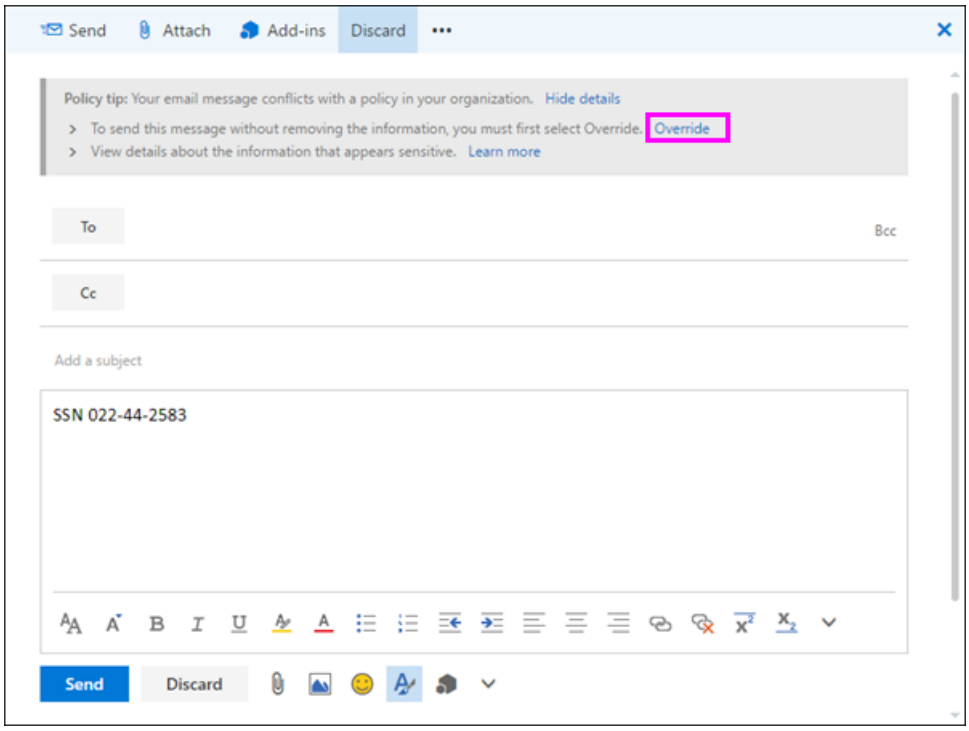
When you compose a new email in Outlook on the web and Outlook 2013 and later, you'll see a policy tip if you add content that matches a rule in a DLP policy, and that rule uses policy tips. The policy tip appears at the top of the message, above the recipients, while the message is being composed.

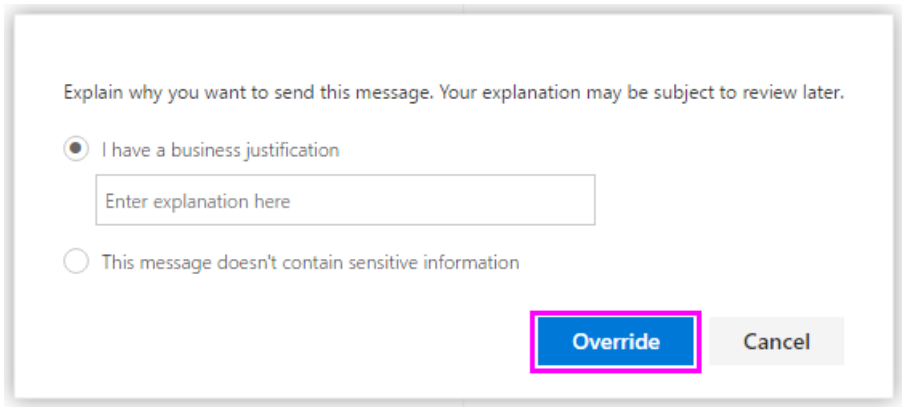


Policy tips work whether the sensitive information appears in the message body, subject line, or even a message attachment as shown here.



If the policy tips are configured to allow override, you can choose **Show Details** > **Override** > enter a business justification or report a false positive > **Override**.





Note that when you add sensitive information to an email, there may be latency between when the sensitive information is added and when the policy tip appears.

Outlook 2013 and later supports showing policy tips for only some conditions

Currently, Outlook 2013 and later supports showing policy tips only for these conditions:

- Content contains
- Content is shared

Note that all of these conditions work in Outlook, where they will match content and enforce protective actions on content. But showing policy tips to users is not yet supported.

Policy tips in the Exchange admin center vs. the Security & Compliance Center

Policy tips can work either with DLP policies and mail flow rules created in the Exchange admin center, or with DLP policies created in the Security & Compliance Center, but not both. This is because these policies are stored in different locations, but policy tips can draw only from a single location.

If you've configured policy tips in the Exchange admin center, any policy tips that you configure in the Security & Compliance Center won't appear to users in Outlook on the web and Outlook 2013 and later until you turn off the tips in the Exchange admin center. This ensures that your current Exchange mail flow rules (also known as transport rules) will continue to work until you choose to switch over to the Security & Compliance Center.

Note that while policy tips can draw only from a single location, email notifications are always sent, even if you're using DLP policies in both the Security & Compliance Center and the Exchange admin center.

Default text for policy tips in email

By default, policy tips display text similar to the following for email.

IF THE DLP POLICY RULE DOES THIS...	THEN THE DEFAULT POLICY TIP SAYS THIS...
Sends a notification but doesn't allow override	Your email conflicts with a policy in your organization.
Blocks access, sends a notification, and allows override	Your email conflicts with a policy in your organization.
Blocks access and sends a notification	Your email conflicts with a policy in your organization.

Policy tips in Excel, PowerPoint, and Word

When people work with sensitive content in the desktop versions of Excel, PowerPoint, and Word, policy tips can notify them in real time that the content conflicts with a DLP policy. This requires that:

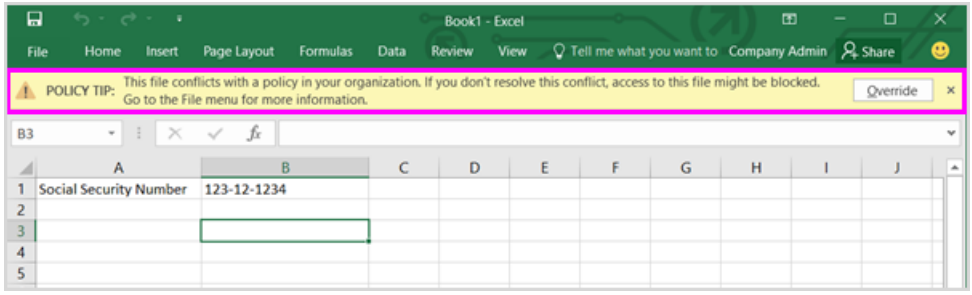
- The Office document is stored on a OneDrive for Business site or SharePoint Online site.
- The site is included in a DLP policy that's configured to use policy tips.

Office desktop programs automatically sync DLP policies directly from Office 365, and then scan your documents to ensure that they don't conflict with your DLP policies and display policy tips in real time.

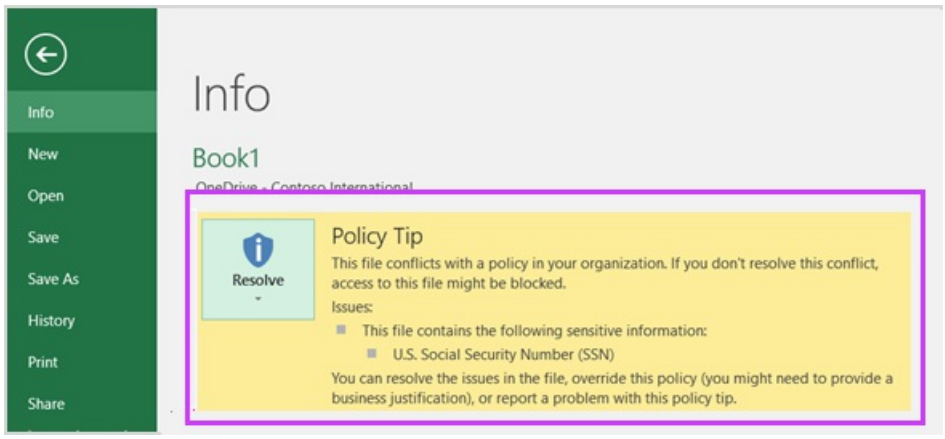
> **NOTE**
> Office desktop apps scan documents themselves to determine if DLP policy tips should be shown; they do not show policy tips that SharePoint Online sites or OneDrive for Business sites have already determined should be shown on a file. As a result, you may not always see a DLP policy tip in the desktop apps that you see in the SharePoint Online sites or OneDrive for Business sites. In contrast, the Office applications on the web only show DLP policy tips that SharePoint Online sites or OneDrive for Business sites have already determined should be shown.

Depending on how you configure the policy tips in the DLP policy, people can choose to simply ignore the policy tip, override the policy with or without a business justification, or report a false positive.

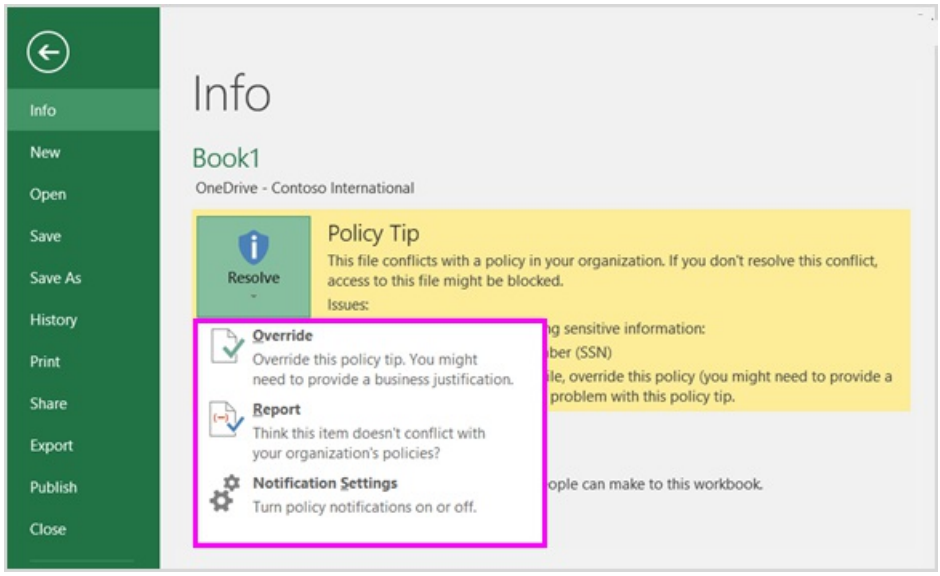
Policy tips appear on the Message Bar.



And policy tips also appear in the Backstage view (on the **File** tab).



If policy tips in the DLP policy are configured with these options, you can choose **Resolve** to **Override** a policy tip or **Report** a false positive.



In each of these Office desktop programs, people can choose to turn off policy tips. If turned off, policy tips that are simple notifications will not appear on the Message Bar or Backstage view (on the **File** tab). However, policy tips about blocking and overriding will still appear, and they will still receive the email notification. In addition, turning off policy tips does not exempt the document from any DLP policies that have been applied to it.

Default text for policy tips in Excel 2016, PowerPoint 2016, and Word 2016

By default, policy tips display text similar to the following on the Message Bar and Backstage view of an open document. The notification text is configured separately for each rule, so the text that's displayed differs depending on which rule is matched.

IF THE DLP POLICY RULE DOES THIS...	THEN THE DEFAULT POLICY TIP SAYS THIS...
Sends a notification but doesn't allow override	This file conflicts with a policy in your organization. Go to the **File** menu for more information.
Blocks access, sends a notification, and allows override	This file conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked. Go to the **File** menu for more information.
Blocks access and sends a notification	This file conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked. Go to the **File** menu for more information.

Custom text for policy tips in Excel, PowerPoint, and Word

You can customize the text for policy tips separately from the email notification. Unlike custom text for email notifications (see above section), custom text for policy tips does not accept HTML or tokens. Instead, custom text for policy tips is plain text only with a 256-character limit.

What the DLP policy templates include

11/2/2020 • 28 minutes to read • Edit Online

Data loss prevention (DLP) in the Security & Compliance Center includes ready-to-use policy templates that address common compliance requirements, such as helping you to protect sensitive information subject to the U.S. Health Insurance Act (HIPAA), U.S. Gramm-Leach-Bliley Act (GLBA), or U.S. Patriot Act. This topic lists all of the policy templates, what types of sensitive information they look for, and what the default conditions and actions are. This topic does not include every detail of how each policy template is configured; instead, the topic presents with you enough information to help you decide which template is the best starting point for your scenario. Remember, you can customize these policy templates to meet your specific requirements.

Australia Financial Data

Create a DLP policy to protect documents with FCI or other properties

2/18/2021 • 7 minutes to read • Edit Online

Microsoft 365 data loss prevention (DLP) policies can use classification properties or item properties to identify sensitive items. For example you can use:

- Windows Server File Classification infrastructure (FCI) properties
- SharePoint document properties
- third-party system document properties

For example, your organization might use Windows Server FCI to identify items with personal data such as social security numbers, and then classify the document by setting the **Personally Identifiable Information** property to **High**, **Moderate**, **Low**, **Public**, or **Not PII** based on the type and number of occurrences of personal data found in the document.

In Microsoft 365, you can create a DLP policy that identifies documents that have that property set to specific values, such as **High** and **Medium**, and then takes an action such as blocking access to those files. The same policy can have another rule that takes a different action if the property is set to **Low**, such as sending an email notification. In this way, DLP integrates with Windows Server FCI and can help protect Office documents uploaded or shared to Microsoft 365 from Windows Server-based file servers.

A DLP policy simply looks for a specific property name/value pair. Any document property can be used, as long as the property has a corresponding managed property for SharePoint search. For example, a SharePoint site collection might use a content type named **Trip Report** with a required field named **Customer**. Whenever a person creates a trip report, they must enter the customer name. This property name/value pair can also be used in a DLP policy—for example, if you want a rule that blocks access to the document for guests when the **Customer** field contains **Contoso**.

If you want to apply your DLP policy to content with specific Microsoft 365 labels, you should not follow the steps here. Instead, learn how to Using a retention label as a condition in a DLP policy.

Before you create the DLP policy

Before you can use a Windows Server FCI property or other property in a DLP policy, you need to create a managed property in the SharePoint admin center. Here's why.

In SharePoint Online and OneDrive for Business, the search index is built up by crawling the content on your sites. The crawler picks up content and metadata from the documents in the form of crawled properties. The search schema helps the crawler decide what content and metadata to pick up. Examples of metadata are the author and the title of a document. However, to get the content and metadata from the documents into the

search index, the crawled properties must be mapped to managed properties. Only managed properties are kept in the index. For example, a crawled property related to author is mapped to a managed property related to author.

> **NOTE**
>
> Be sure to use a managed property name and not a crawled property name when creating DLP rules using the `ContentPropertyContainsWords` condition.

This is important because DLP uses the search crawler to identify and classify sensitive information on your sites, and then store that sensitive information in a secure portion of the search index. When you upload a document to Office 365, SharePoint automatically creates crawled properties based on the document properties. But to use an FCI or other property in a DLP policy, that crawled property needs to be mapped to a managed property so that content with that property is kept in the index.

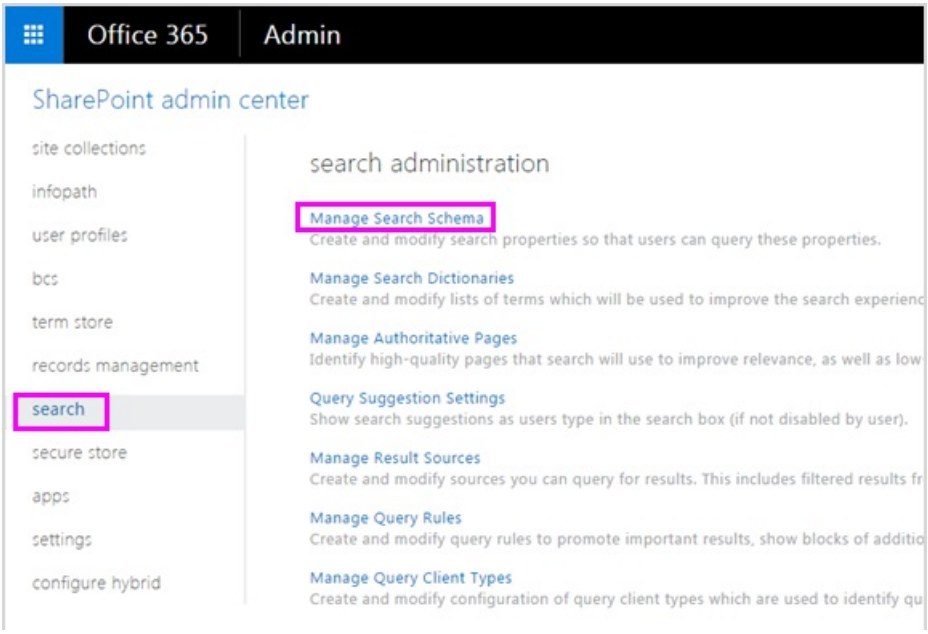
For more information on search and managed properties, see Manage the search schema in SharePoint Online.

Step 1: Upload a document with the needed property to Office 365

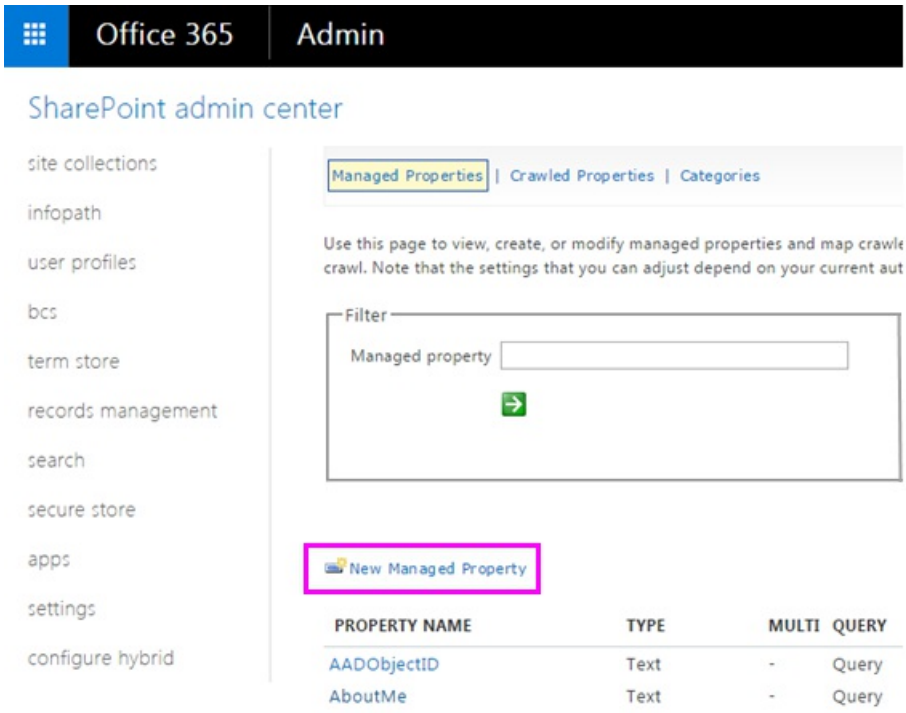
You first need to upload a document with the property that you want to reference in your DLP policy. Microsoft 365 will detect the property and automatically create a crawled property from it. In the next step, you'll create a managed property, and then map the managed property to this crawled property.

Step 2: Create a managed property

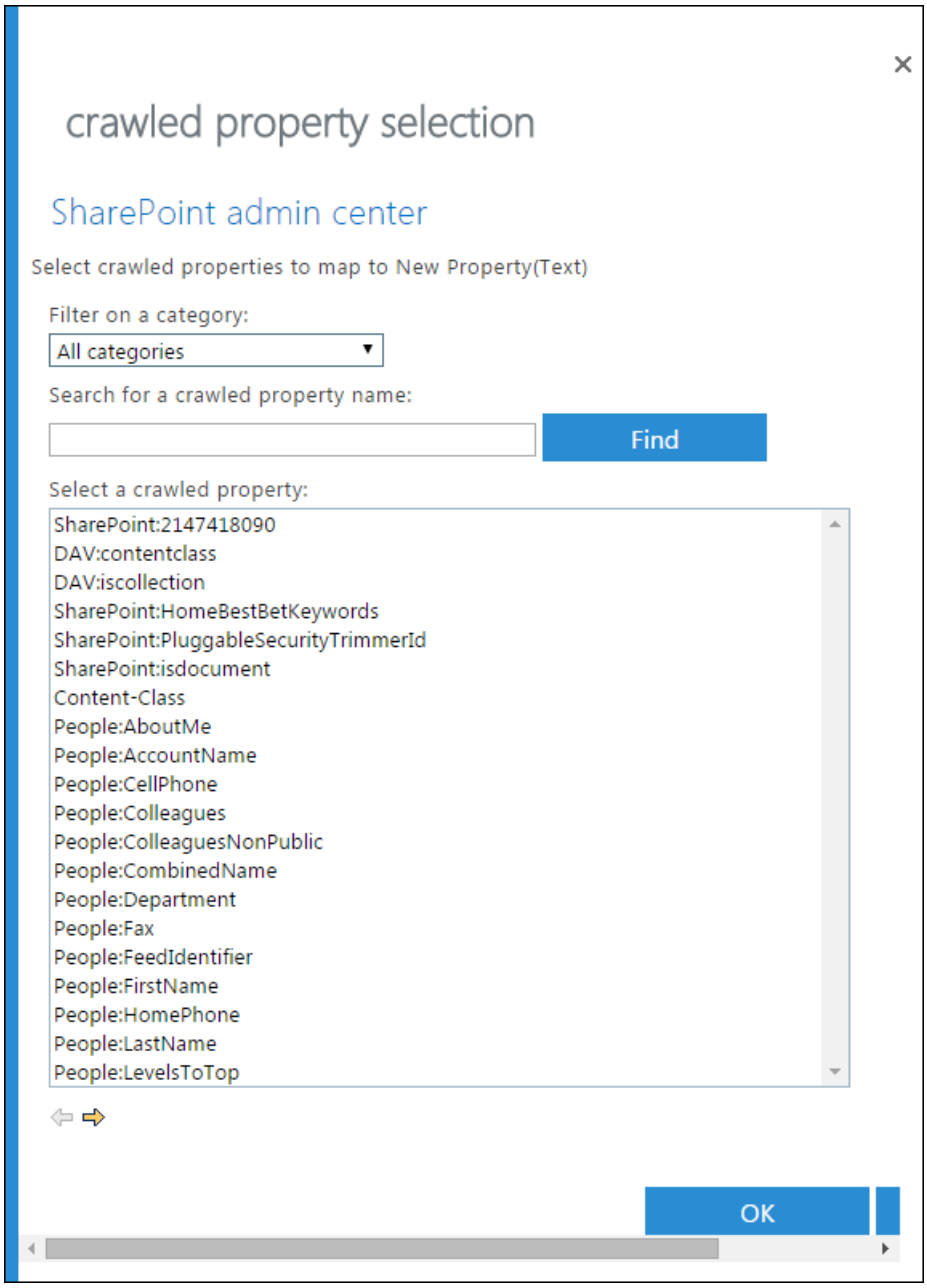
1. Sign in to the Microsoft 365 admin center.
2. In the left navigation, choose **Admin centers** > **SharePoint**. You're now in the SharePoint admin center.
3. In the left navigation, choose **search** > on the **search administration** page > **Manage Search Schema**.



4. On the **Managed Properties** page > **New Managed Property**.



5. Enter a name and description for the property. This name is what will appear in your DLP policies.
6. For **Type**, choose **Text**.
7. Under **Main characteristics**, select **Queryable** and **Retrievable**.
8. Under **Mappings to crawled properties** > **Add a mapping**.
9. In the **crawled property selection** dialog box > find and select the crawled property that corresponds to the Windows Server FCI property or other property that you will use in your DLP policy > **OK**.



10. At the bottom of the page > **OK**.

Create a DLP policy that uses an FCI property or other property

In this example, an organization is using FCI on its Windows Server-based file servers; specifically, they're using the FCI classification property named **Personally Identifiable Information** with possible values of **High**, **Moderate**, **Low**, **Public**, and **Not PII**. Now they want to use their existing FCI classification in their DLP policies in Office 365.

First, they follow the steps above to create a managed property in SharePoint Online, which maps to the crawled property created automatically from the FCI property.

Next, they create a DLP policy with two rules that both use the condition **Document properties contain any of these values**:

- **FCI PII content - High, Moderate** The first rule restricts access to the document if the FCI classification property **Personally Identifiable Information** equals **High** or **Moderate** and the document is shared with people outside the organization.
- **FCI PII content - Low** The second rule sends a notification to the document owner if the FCI classification property **Personally Identifiable Information** equals **Low** and the document is shared

with people outside the organization.

Create the DLP policy by using PowerShell

The condition **Document properties contain any of these values** is temporarily not available in the UI of the Security & Compliance Center, but you can still use this condition by using PowerShell. You can use the `New\Set\Get-DlpCompliancePolicy` cmdlets to work with a DLP policy, and use the `New\Set\Get-DlpComplianceRule` cmdlets with the `ContentPropertyContainsWords` parameter to add the condition **Document properties contain any of these values**.

For more information on these cmdlets, see Security & Compliance Center cmdlets.

1. Connect to the Security & Compliance Center using remote PowerShell
2. Create the policy by using `New-DlpCompliancePolicy`.

This PowerShell creates a DLP policy that applies to all locations.

```
New-DlpCompliancePolicy -Name FCI_PII_policy -ExchangeLocation All -SharePointLocation All -OneDriveLocation
All -Mode Enable
```

3. Create the two rules described above by using `New-DlpComplianceRule`, where one rule is for the **Low** value, and another rule is for the **High** and **Moderate** values.

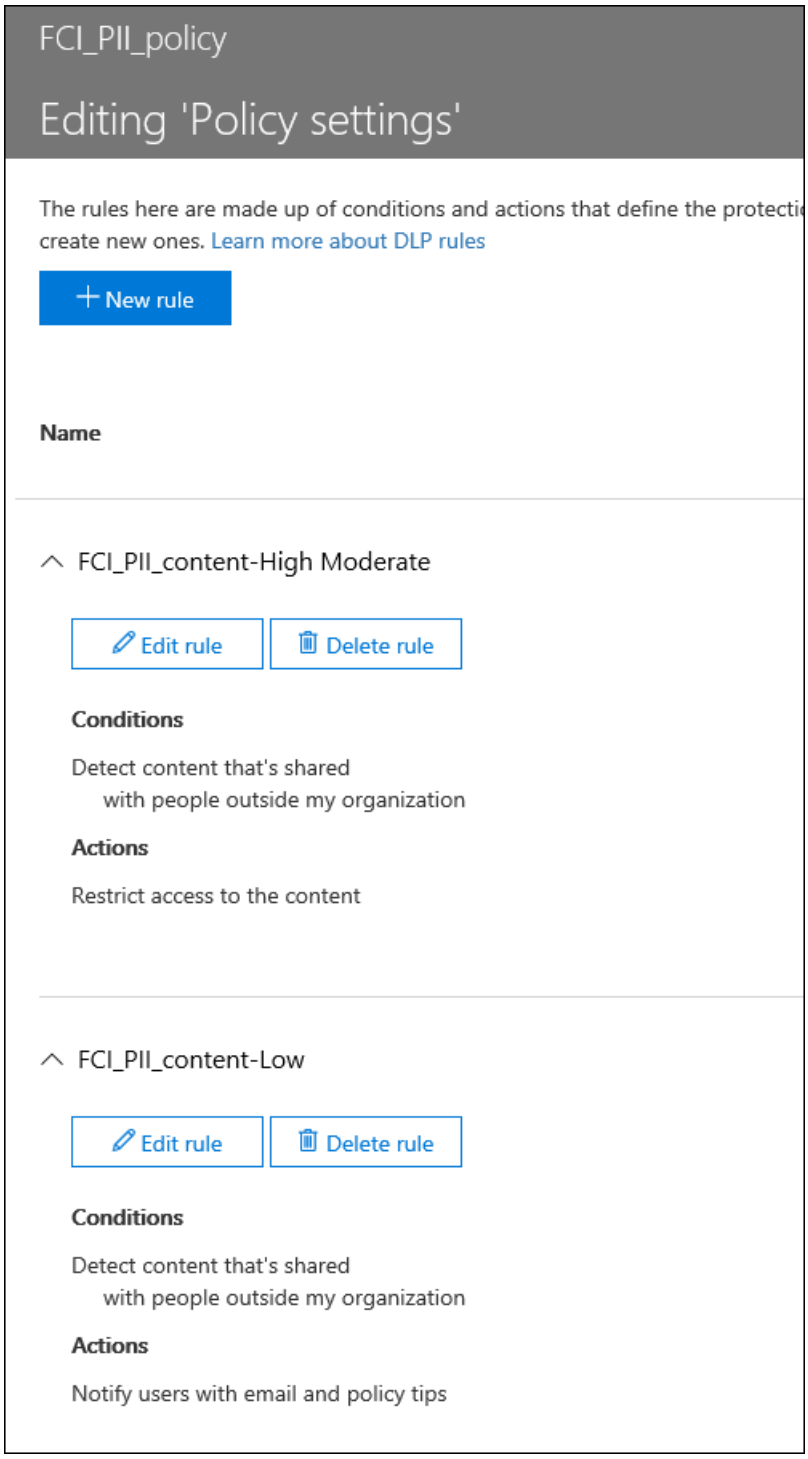
   Here is a PowerShell example that creates these two rules. The property name/value pairs are enclosed in quotation marks, and a property name may specify multiple values separated by commas with no spaces, like `"<Property1>:<Value1>,<Value2>","<Property2>:<Value3>,<Value4>"....`

   ```
   New-DlpComplianceRule -Name FCI_PII_content-High,Moderate -Policy FCI_PII_policy -AccessScope
   NotInOrganization -BlockAccess $true -ContentPropertyContainsWords "Personally Identifiable
   Information:High,Moderate" -Disabled $falseNew-DlpComplianceRule -Name FCI_PII_content-Low -Policy
   FCI_PII_policy -AccessScope NotInOrganization -BlockAccess $false -ContentPropertyContainsWords
   "Personally Identifiable Information:Low" -Disabled $false -NotifyUser Owner
   ```

   Windows Server FCI includes many built-in properties, including **Personally Identifiable Information** used in this example. The possible values for each property can be different for every organization. The **High**, **Moderate**, and **Low** values used here are only an example. For your organization, you can view the Windows Server FCI classification properties with their possible values in the file Server Resource Manager on the Windows Server-based file server. For more information, see Create a classification property.

When you finish, your policy should have two new rules that both use the **Document properties contain any of these values** condition. This condition won't appear in the UI, though the other conditions, actions, and settings will appear.

One rule blocks access to content where the **Personally Identifiable Information** property equals **High** or **Moderate**. A second rule sends a notification about content where the **Personally Identifiable Information** property equals **Low**.



After you create the DLP policy

Doing the steps in the previous sections will create a DLP policy that will quickly detect content with that property, but only if that content is newly uploaded (so that the content's indexed), or if that content is old but just edited (so that the content's re-indexed).

To detect content with that property everywhere, you may want to manually request that your library, site, or site collection be re-indexed, so that the DLP policy is aware of all the content with that property. In SharePoint Online, content is automatically crawled based on a defined crawl schedule. The crawler picks up content that has changed since the last crawl and updates the index. If you need your DLP policy to protect content before the next scheduled crawl, you can take these steps.

Caution

Re-indexing a site can cause a massive load on the search system. Don't re-index your site unless your scenario absolutely requires it.

For more information, see Manually request crawling and re-indexing of a site, a library or a list.

Reindex a site (optional)

1. On the site, choose **Settings** (gear icon in upper right) > **Site Settings**.
2. Under **Search**, choose **Search and offline availability** > **Reindex site**.

View the reports for data loss prevention

11/2/2020 • 3 minutes to read • Edit Online

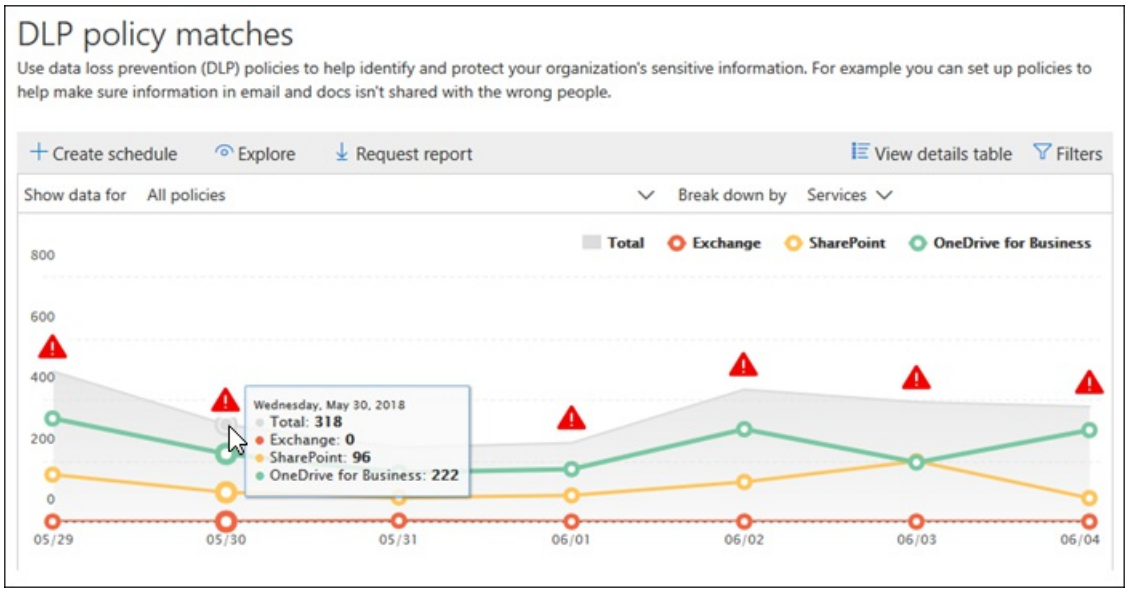
After you create your data loss prevention (DLP) policies, you'll want to verify that they're working as you intended and helping you to stay compliant. With the DLP reports in the Security & Compliance Center, you can quickly view:

- **DLP policy matches** This report shows the count of DLP policy matches over time. You can filter the report by date, location, policy, or action. You can use this report to:
  - Tune or refine your DLP policies as you run them in test mode. You can view the specific rule that matched the content.
  - Focus on specific time periods and understand the reasons for spikes and trends.
  - Discover business processes that violate your organization's DLP policies.
  - Understand any business impact of the DLP policies by seeing what actions are being applied to content.
  - Verify compliance with a specific DLP policy by showing any matches for that policy.
  - View a list of top users and repeat users who are contributing to incidents in your organization.
  - View a list of the top types of sensitive information in your organization.
- **DLP incidents** This report also shows policy matches over time, like the policy matches report. However, the policy matches report shows matches at a rule level; for example, if an email matched three different rules, the policy matches report shows three different line items. By contrast, the incidents report shows matches at an item level; for example, if an email matched three different rules, the incidents report shows a single line item for that piece of content.

  Because the report counts are aggregated differently, the policy matches report is better for identifying matches with specific rules and fine tuning DLP policies. The incidents report is better for identifying specific pieces of content that are problematic for your DLP policies.
- **DLP false positives and overrides** If your DLP policy allows users to override it or report a false positive, this report shows a count of such instances over time. You can filter the report by date, location, or policy. You can use this report to:
  - Tune or refine your DLP policies by seeing which policies incur a high number of false positives.
  - View the justifications submitted by users when they resolve a policy tip by overriding the policy.
  - Discover where DLP policies conflict with valid business processes by incurring a high number of user overrides.

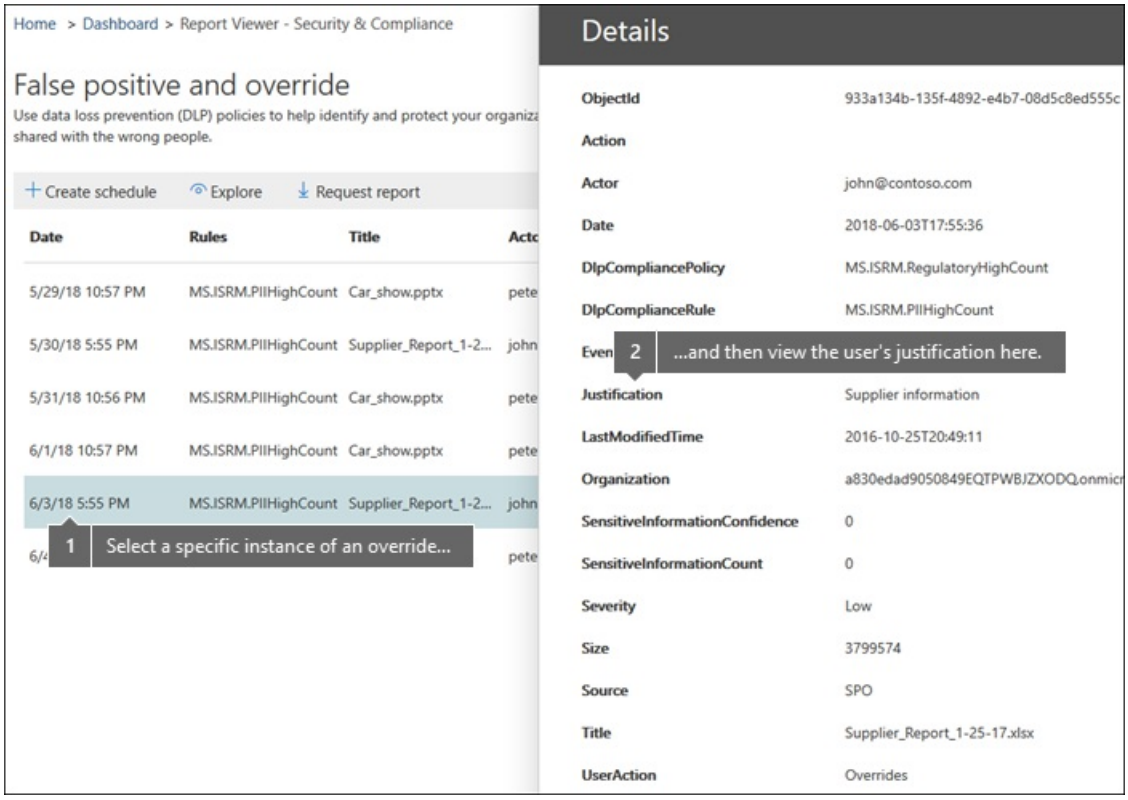
All DLP reports can show data from the most recent four-month time period. The most recent data can take up to 24 hours to appear in the reports.

You can find these reports in the Security & Compliance Center > **Reports** > **Dashboard**.



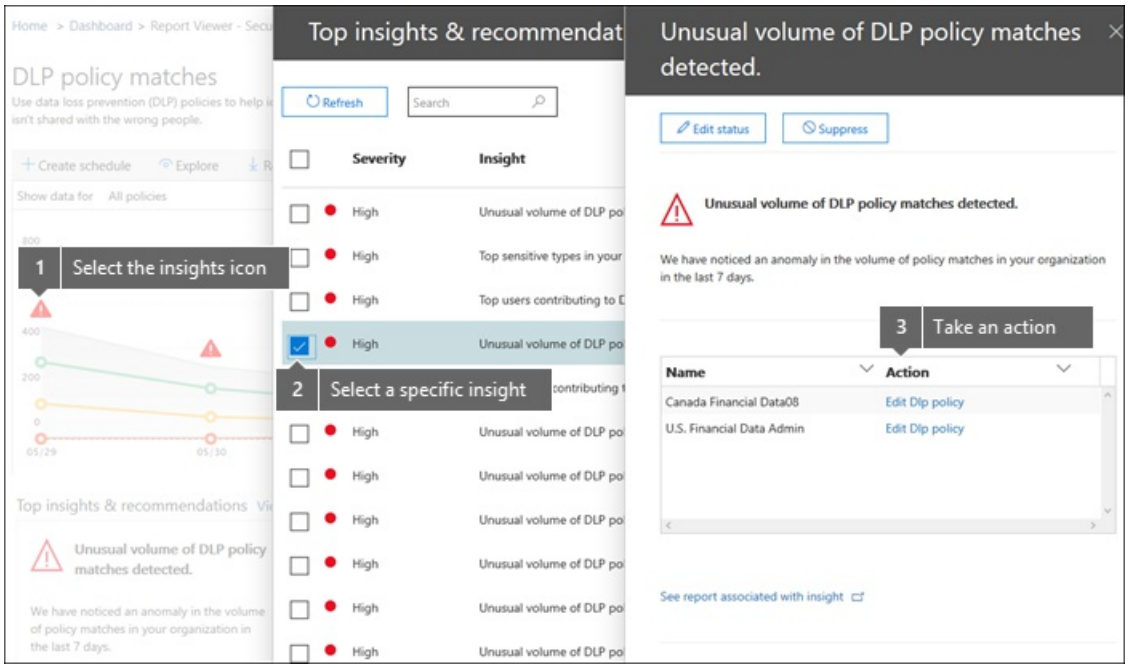
View the justification submitted by a user for an override

If your DLP policy allows users to override it, you can use the false positive and override report to view the text submitted by users in the policy tip.



Take action on insights and recommendations

Reports can show insights and recommendations where you can click the red warning icon to see details about potential issues and take possible remedial action.



Permissions for DLP reports

To view DLP reports in the Security & Compliance Center, you have to be assigned the:

- **Security Reader** role in the Exchange admin center. By default, this role is assigned to the Organization Management and Security Reader role groups in the Exchange admin center.
- **View-Only DLP Compliance Management** role in the Security & Compliance Center. By default, this role is assigned to the Compliance Administrator, Organization Management, Security Administrator, and Security Reader role groups in the Security & Compliance Center.
- **View-Only Recipients** role in the Exchange admin center. By default, this role is assigned to the Compliance Management, Organization Management, and View-Only Organization Management role groups in the Exchange admin center.

Find the cmdlets for the DLP reports

To use most of the cmdlets for the Security & Compliance Center, you need to:

1. Connect to the Security & Compliance Center using remote PowerShell
2. Use any of these Security & Compliance Center cmdlets

However, DLP reports need pull data from across Office 365, including Exchange Online. For this reason, the cmdlets for the DLP reports are available in Exchange Online Powershell—not in Security & Compliance Center Powershell. Therefore, to use the cmdlets for the DLP reports, you need to:

1. Connect to Exchange Online using remote PowerShell
2. Use any of these cmdlets for the DLP reports:
   - Get-DlpDetectionsReport
   - Get-DlpDetailReport

Form a query to find sensitive data stored on sites

11/2/2020 • 5 minutes to read • Edit Online

Users often store sensitive data, such as credit card numbers, social security numbers, or personal, on their sites, and over time this can expose an organization to significant risk of data loss. Documents stored on sites—including OneDrive for Business sites—could be shared with people outside the organization who shouldn't have access to the information. With data loss prevention (DLP) in SharePoint Online, you can discover documents that contain sensitive data throughout your tenant. After discovering the documents, you can work with the document owners to protect the data. This topic can help you form a query to search for sensitive data.

> **NOTE**
>
> Electronic discovery, or eDiscovery, and DLP are premium features that require SharePoint Online Plan 2.

Forming a basic DLP query

There are three parts that make up a basic DLP query: SensitiveType, count range, and confidence range. As illustrated in the following graphic, **SensitiveType:"<type>"** is required, and both**|<count range>** and**|<confidence range>** are optional.

Sensitive type - required

So what is each part? SharePoint DLP queries typically begin with the property `SensitiveType:"` and an information type name from the sensitive information types inventory, and end with a `"`. You can also use the name of a custom sensitive information type that you created for your organization. For example, you might be looking for documents that contain credit card numbers. In such an instance, you'd use the following format: `SensitiveType:"Credit Card Number"`. Because you didn't include count range or confidence range, the query returns every document in which a credit card number is detected. This is the simplest query that you can run, and it returns the most results. Keep in mind that the spelling and spacing of the sensitive type matters.

Ranges - optional

Both of the next two parts are ranges, so let's quickly examine what a range looks like. In SharePoint DLP queries, a basic range is represented by two numbers separated by two periods, which looks like this: `[number]..[number]`. For instance, if `10..20` is used, that range would capture numbers from 10 through 20. There are many different range combinations and several are covered in this topic.

Let's add a count range to the query. You can use count range to define the number of occurrences of sensitive information a document needs to contain before it's included in the query results. For example, if you want your query to return only documents that contain exactly five credit card numbers, use this: `SensitiveType:"Credit Card Number|5"`. Count range can also help you identify documents that pose high degrees of risk. For example, your organization might consider documents with five or more credit card numbers a high risk. To find documents fitting this criterion, you would use this query: `SensitiveType:"Credit Card Number|5.."`. Alternatively, you can find documents with five or fewer credit card

numbers by using this query: `SensitiveType:"Credit Card Number|..5"`.

Confidence range

Finally, confidence range is the level of confidence that the detected sensitive type is actually a match. The values for confidence range work similarly to count range. You can form a query without including a count range. For example, to search for documents with any number of credit card numbers—as long as the confidence range is 85 percent or higher—you would use this query: `SensitiveType:"Credit Card Number|*|85.."`.

> **IMPORTANT**
> The asterisk (`*`) is a wildcard character that means any value works. You can use the wildcard character (`*`) either in the count range or in the confidence range, but not in a sensitive type.

Additional query properties and search operators available in the eDiscovery Center

DLP in SharePoint also introduces the LastSensitiveContentScan property, which can help you search for files scanned within a specific timeframe. For query examples with the `LastSensitiveContentScan` property, see the Examples of complex queries in the next section.

You can use not only DLP-specific properties to create a query, but also standard SharePoint eDiscovery search properties such as `Author` or `FileExtension`. You can use operators to build complex queries. For the list of available properties and operators, see the Using Search Properties and Operators with eDiscovery blog post.

Examples of complex queries

The following examples use different sensitive types, properties, and operators to illustrate how you can refine your queries to find exactly what you're looking for.

QUERY	EXPLANATION
`SensitiveType:"International Banking Account Number (IBAN)"`	The name might seem strange because it's so long, but it's the correct name for that sensitive type. Make sure to use exact names from the sensitive information types inventory. You can also use the name of a custom sensitive information type that you created for your organization.
`SensitiveType:"Credit Card Number|1..4294967295|1..100"`	This returns documents with at least one match to the sensitive type "Credit Card Number." The values for each range are the respective minimum and maximum values. A simpler way to write this query is `SensitiveType:"Credit Card Number"`, but where's the fun in that?
`SensitiveType:"Credit Card Number| 5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018"`	This returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018.
`SensitiveType:"Credit Card Number| 5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018" NOT FileExtension:XLSX`	This returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018. Files with an XLSX extension aren't included in the query results. `FileExtension` is one of many properties that you can include in a query. For more information, see Using Search Properties and Operators with eDiscovery.
`SensitiveType:"Credit Card Number" OR SensitiveType:"U.S. Social Security Number (SSN)"`	This returns documents that contain either a credit card number or a social security number.

Examples of queries to avoid

Not all queries are created equal. The following table gives examples of queries that don't work with DLP in SharePoint and describes why.

UNSUPPORTED QUERY	REASON	
`SensitiveType:"Credit Card Number|.."`	You must add at least one number.	
`SensitiveType:"NotARule"`	"NotARule" isn't a valid sensitive type name. Only names in the sensitive information types inventory work in DLP queries.	
`SensitiveType:"Credit Card Number|0"`	Zero isn't valid as either the minimum value or the maximum value in a range.	
`SensitiveType:"Credit Card Number"`	It's might be difficult to see, but there's extra white space between "Credit" and "Card" that makes the query invalid. Use exact sensitive type names from the sensitive information types inventory.	
`SensitiveType:"Credit Card Number|1. .3"`	The two-period portion shouldn't be separated by a space.	
`SensitiveType:"Credit Card Number| |1..|80.."`	There are too many pipe delimiters (	). Follow this format instead: `SensitiveType: "Credit Card Number|1..|80.."`
`SensitiveType:"Credit Card Number|1..|80..101"`	Because confidence values represent a percentage, they can't exceed 100. Choose a number from 1 through 100 instead.

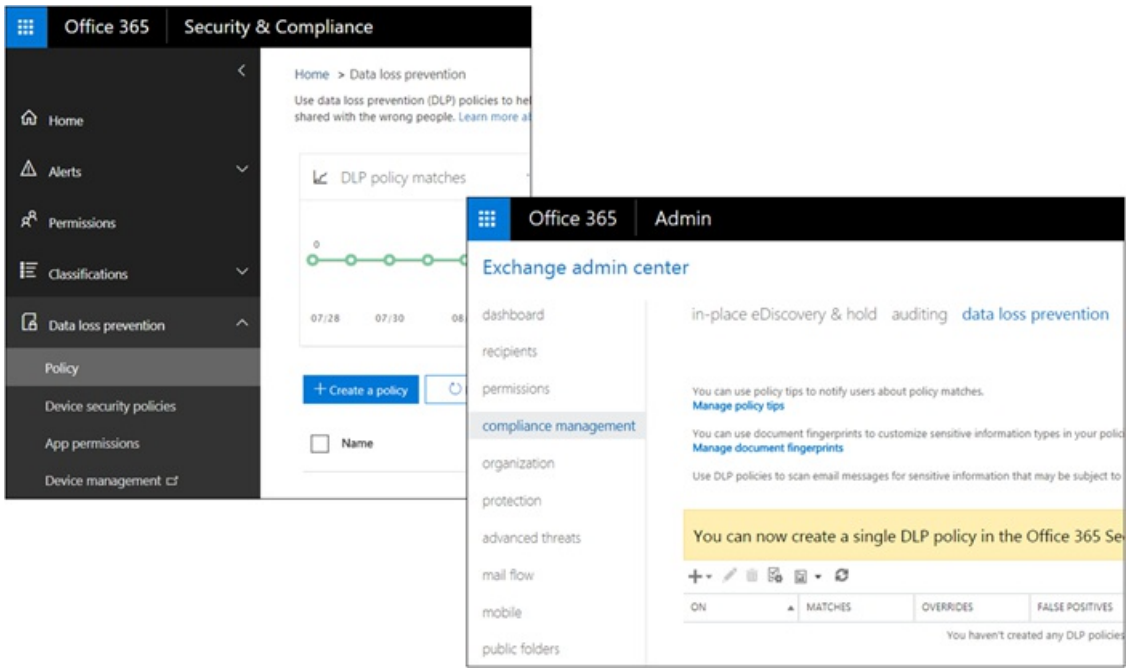
How DLP works between the Security & Compliance Center and Exchange admin center

5/5/2020 • 2 minutes to read • Edit Online

In Office 365, you can create a data loss prevention (DLP) policy in two different admin centers:

- In the **Security & Compliance Center**, you can create a single DLP policy to help protect content in SharePoint, OneDrive, Exchange, and now Microsoft Teams. When possible, we recommend that you create a DLP policy here. For more information, see DLP in the Security & Compliance Center.
- In the **Exchange admin center**, you can create a DLP policy to help protect content only in Exchange. This policy can use Exchange mail flow rules (also known as transport rules), so it has more options specific to handling email. For more information, see DLP in the Exchange admin center.

DLP polices created in these admin centers work side by side - this topic explains how.



How DLP in the Security & Compliance Center works with DLP and mail flow rules in the Exchange admin center

After you create a DLP policy in the Security & Compliance Center, the policy is deployed to all of the locations included in the policy. If the policy includes Exchange Online, the policy's synced there and enforced in exactly the same way as a DLP policy created in the Exchange admin center.

If you've created DLP policies in the Exchange admin center, those policies will continue to work side by side with any policies for email that you create in the Security & Compliance Center. But note that rules created in the Exchange admin center take precedence. All Exchange mail flow rules are processed first, and then the DLP rules from the Security & Compliance Center are processed.

This means that:

- Messages that are blocked by Exchange mail flow rules won't get scanned by DLP rules created in the Security & Compliance Center.

- If an Exchange mail flow rule modifies a message in a way that causes it to match a DLP policy in the Security & Compliance Center - such as adding external users - then the DLP rules will detect this and enforce the policy as needed.

Also note that Exchange mail flow rules that use the "stop processing" action don't affect the processing of DLP rules in the Security & Compliance Center - they'll still be processed.

Policy tips in the Security & Compliance Center vs. the Exchange admin center

Policy tips can work either with DLP policies and mail flow rules created in the Exchange admin center, or with DLP policies created in the Security & Compliance Center, but not both. This is because these policies are stored in different locations, but policy tips can draw only from a single location.

If you've configured policy tips in the Exchange admin center, any policy tips that you configure in the Security & Compliance Center won't appear to users in Outlook on the web and Outlook 2013 and later until you turn off the tips in the Exchange admin center. This ensures that your current Exchange mail flow rules will continue to work until you choose to switch over to the Security & Compliance Center.

Note that while policy tips can draw only from a single location, email notifications are always sent, even if you're using DLP policies in both the Security & Compliance Center and the Exchange admin center.

Configure and view alerts for DLP polices (preview)

11/2/2020 • 5 minutes to read • Edit Online

This article shows you how to define rich alert policies that are linked to your data loss prevention (DLP) policies. You'll see how to use the new DLP alert management dashboard in the Microsoft 365 compliance center to view alerts, events, and associated metadata for DLP policy violations.

Features

The following features are part of this preview:

- **DLP alert management dashboard**: In the Microsoft 365 compliance center, this dashboard shows alerts for DLP policies that are enforced on the following workloads:
  - Exchange
  - SharePoint
  - OneDrive
  - Teams
  - Devices
- **Advanced alert configuration options**: These options are part of the DLP policy authoring flow. Use them to create rich alert configurations. You can create a single-event alert or an aggregated alert, based on the number of events or the size of the leaked data.

Before you begin

Before you begin, make sure you have the necessary prerequisites:

- Licensing for the DLP alerts management dashboard
- Licensing for alert configuration options
- Roles

Licensing for the DLP alert management dashboard

All eligible tenants for Office 365 DLP can access the new DLP alert management dashboard. To get started, you should be eligible for Office 365 DLP for Exchange Online, SharePoint Online, and OneDrive for Business. For more information about the licensing requirements for Office 365 DLP, see Which licenses provide the rights for a user to benefit from the service?.

Customers who participate in the Endpoint DLP public preview or who are eligible for Teams DLP will see their endpoint DLP policy alerts and Teams DLP policy alerts in the DLP alert management dashboard.

Licensing for alert configuration options

- **Single-event alert configuration**: Organizations that have an E1, F1, or G1 subscription or an E3 or G3 subscription can create alert policies only where an alert is triggered every time an activity occurs.
- **Aggregated alert configuration**: To configure aggregate alert policies based on a threshold, you must have either of the following configurations:
  - An E5 or G5 subscription
  - An E1, F1, or G1 subscription or an E3 or G3 subscription that includes one of the following features:
    - Office 365 Advanced Threat Protection Plan 2
    - Microsoft 365 E5 Compliance

- Microsoft 365 eDiscovery and Audit add-on license

Roles

If you want to view the DLP alert management dashboard or to edit the alert configuration options in a DLP policy, you must be a member of one of these role groups:

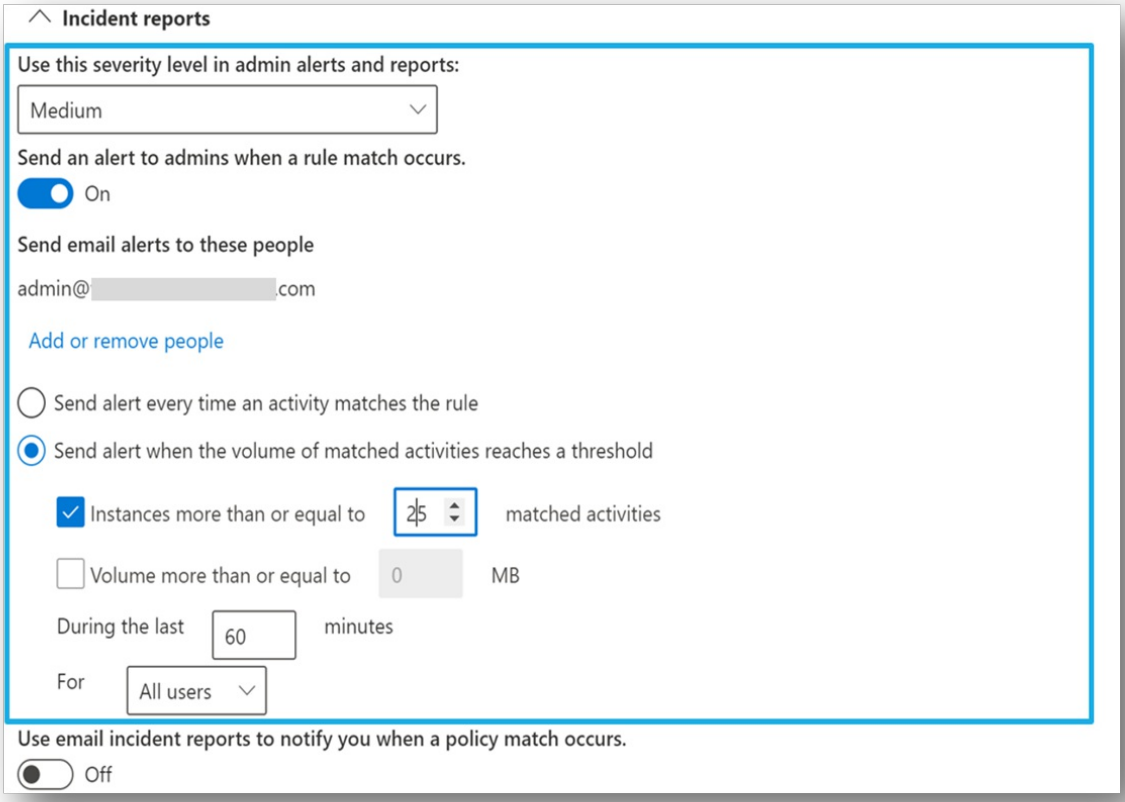
- Compliance Administrator
- Compliance Data Administrator
- Security Administrator
- Security Operator
- Security Reader

To access the DLP alert management dashboard, you need the Manage alerts role and either of the following roles:

- DLP Compliance Management
- View-Only DLP Compliance Management

Alert configuration experience

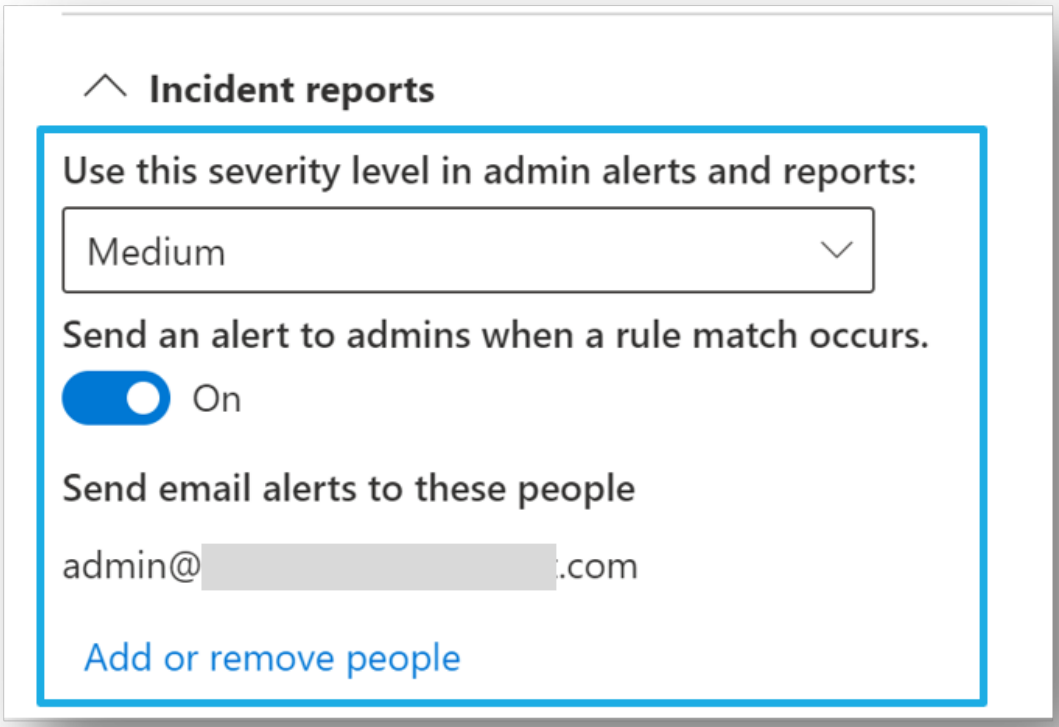
If you're eligible for aggregated alert configuration options, then you see the following options inline in the DLP policy authoring experience.



You can use these alert configuration options to configure a setting that defines how often a DLP rule match can occur before an alert is triggered. This configuration allows you to set up a policy to generate an alert every time an activity matches the policy conditions or when a certain threshold is exceeded, based on the number of activities or based on the volume of exfiltrated data.

If you're eligible for single-event alert configuration options, then you see the following alert configuration option in the DLP policy authoring experience. Use this option to create an alert that's raised every time a DLP

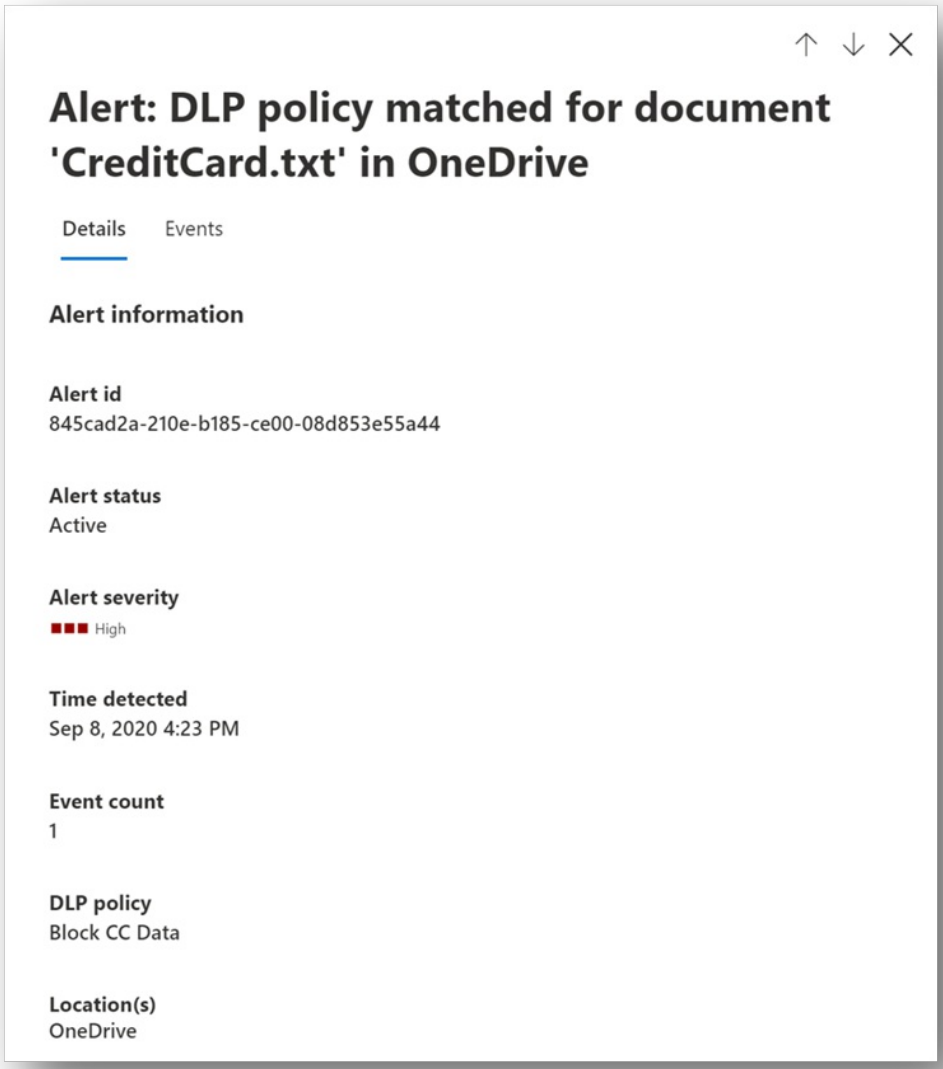
rule match happens because of a user activity.



DLP alert management dashboard

To work with the DLP alert management dashboard:

1. In the Microsoft 365 compliance center, go to **Data Loss Prevention**.
2. Select the **Alerts** tab to view the DLP alerts dashboard.
   - Choose filters to refine the list of alerts. Choose **Customize columns** to list the properties you want to see. You can also choose to sort the alerts in ascending or descending order in any column.
   - Select an alert to see details:



3. Select the **Events** tab to view all of the events associated with the alert. You can choose a particular event to view its details. The following table shows some of the event details.

CATEGORY	PROPERTY NAME	DESCRIPTION	APPLICABLE EVENT TYPES
Event details			
	Id	Unique ID associated with the event	All events
	Location	Workload where the event was detected	All events
	Time of activity	Time of the user activity that caused the DLP violation	All events
Impacted entities			
	User	User who caused the DLP violation	All events

CATEGORY	PROPERTY NAME	DESCRIPTION	APPLICABLE EVENT TYPES
	Hostname	Host name of the machine where the DLP violation was detected	Devices events
	IP address	IP address of the machine	Devices events
	File path	Absolute path of the file involved in the violation	SharePoint, OneDrive, and Devices events
	Email recipients	Recipients of the email that violated the DLP policy	Exchange events
	Email subject	Subject of the email that violated the DLP policy	Exchange events
	Email attachments	Names of the attachments in the email that violated the DLP policy	Exchange events
	Site owner	Name of the site owner	SharePoint and OneDrive events
	Site URL	Full URL of the SharePoint or OneDrive site	SharePoint and OneDrive events
	File created	Time of file creation	SharePoint and OneDrive events
	File last modified	Time of the last modification of the file	SharePoint and OneDrive events
	File size	Size of the file	SharePoint and OneDrive events
	File owner	Owner of the file	SharePoint and OneDrive events
Policy details			
	DLP policy matched	Name of the DLP policy that was matched	All events
	Rule matched	Name of the DLP rule in the DLP policy that was matched	All events
	Sensitive info types detected	Sensitive information types that were detected as a part of the DLP policy	All events

CATEGORY	PROPERTY NAME	DESCRIPTION	APPLICABLE EVENT TYPES
	Actions taken	Actions taken as a part of the matched DLP policy	All events
	User overrode policy	Whether the user overrode the policy through the policy tip	All events
	Override justification text	Justification provided to override the policy tip	All events

4. Select the **Sensitive Info Types** tab to view details about the sensitive information types detected in the content. Details include confidence and count.

5. After you investigate the alert, choose **Manage alert** to change the status (**Active**, **Investigating**, **Dismissed**, or **Resolved**). You can also add comments and assign the alert to someone in your organization.

   - To see the history of workflow management, choose **Management log**.
   - After you take the required action for the alert, set the status of the alert to **Resolved**.

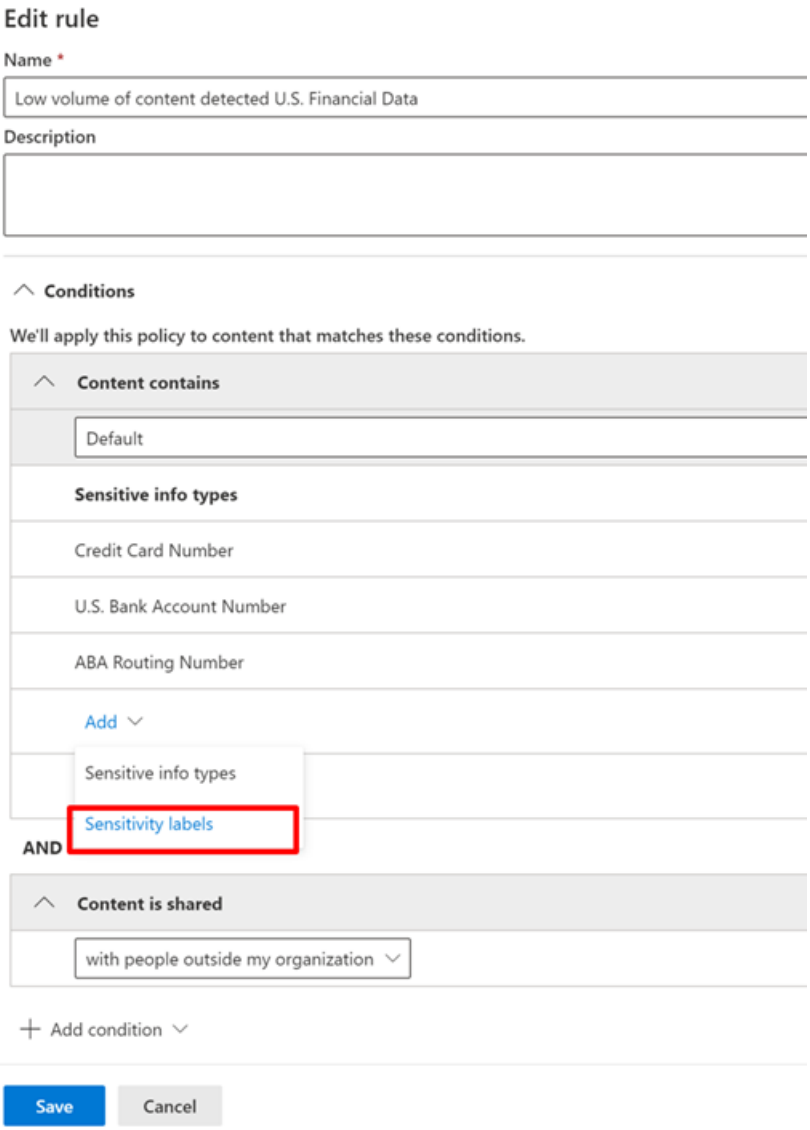
Use sensitivity labels as conditions in DLP policies (preview)

11/2/2020 • 2 minutes to read • Edit Online

You can use sensitivity labels as a condition in DLP policies for these location:

- Exchange Online email messages
- SharePoint Online
- OneDrive for Business sites
- Windows 10 devices

Sensitivity labels appear as an option in the **Content contains** list.



IMPORTANT

Sensitivity Labels as a condition will not be available if you have selected **Teams chat and channel messages** as a location to apply the DLP policy.

Supported items, scenarios, and policy tips

You can use sensitivity labels as conditions on these items and in these scenarios.

Supported items

SERVICE	ITEM TYPE	AVAILABLE TO POLICY TIP	ENFORCEABLE
Exchange	email message	yes	yes
Exchange	email attachment	no *	no *
SharePoint Online	items in SharePoint Online	yes	yes
OneDrive for Business	items	yes	yes
Teams	Teams and channel messages	not applicable	not applicable
Teams	attachments	yes **	yes **
Windows 10 devices (preview)	items	yes	yes
MCAS (preview)	items	yes	yes

* DLP detection of sensitivity labels on emails are supported. DLP detection of sensitivity labeled email attachments are not.

** Attachments sent in Teams over 1:1 chat or channels are automatically uploaded to OneDrive for Business and SharePoint. So if SharePoint Online or OneDrive for Business are included as locations in your DLP policy, then labeled attachments sent in Teams will be automatically included in the scope of this condition. Teams as a location does not need to be selected in the DLP policy.

Supported scenarios

- DLP Admin will be able to see a list of all sensitivity labels in the tenant when they choose to include one or more sensitivity labels as a condition.
- Using sensitivity labels as a condition is supported across all workloads as indicated in the support matrix above.
- DLP policy tips will continue to be shown across workloads (except Outlook Win32) for DLP policies which contain sensitivity label as a condition.
- Sensitivity labels will also appear as a part of the incident report email if a DLP policy with sensitivity label as a condition is matched.
- Sensitivity label details will also be shown in the DLP rule match audit log for a DLP policy match which contains sensitivity label as a condition.

Support policy tips

WORKLOAD	POLICY TIPS SUPPORTED/NOT SUPPORTED
OWA	supported

WORKLOAD	POLICY TIPS SUPPORTED/NOT SUPPORTED
Outlook Win 32	not supported
SharePoint	supported
OneDrive for Business	supported
endpoint devices	not supported

Use data loss prevention policies for non-Microsoft cloud apps (preview)

11/2/2020 • 2 minutes to read • Edit Online

Data loss prevention (DLP) policies to non-Microsoft cloud apps are part of the Microsoft 365 DLP suite of features; using these features, you can discover and protect sensitive items across Microsoft 365 services. For more information about all Microsoft DLP offerings, see Overview of data loss prevention.

You can use DLP policies to non-Microsoft cloud apps to monitor and detect when sensitive items are used and shared via non-Microsoft cloud apps. Using these policies gives you the visibility and control that you need to ensure that they're correctly used and protected, and it helps prevent risky behavior that might compromise them.

Before you begin

SKU/subscriptions licensing

Before you start using DLP policies to non-Microsoft cloud apps, confirm your Microsoft 365 subscription and any add-ons. To access and use this functionality, you must have one of these subscriptions or add-ons:

- Microsoft 365 E5
- Microsoft 365 E5 Compliance
- Microsoft 365 E5 Security

Prepare your Cloud App Security environment

DLP policies to non-Microsoft cloud apps use Cloud App Security DLP capabilities. To use it, you should prepare your Cloud App Security environment. For instructions, see Set instant visibility, protection, and governance actions for your apps.

Connect a non-Microsoft cloud app

To use DLP policy to a specific non-Microsoft cloud app, the app must be connected to Cloud App Security. For information, see:

- Connect Box
- Connect Dropbox
- Connect G-Suite
- Connect Salesforce
- Connect Cisco Webex

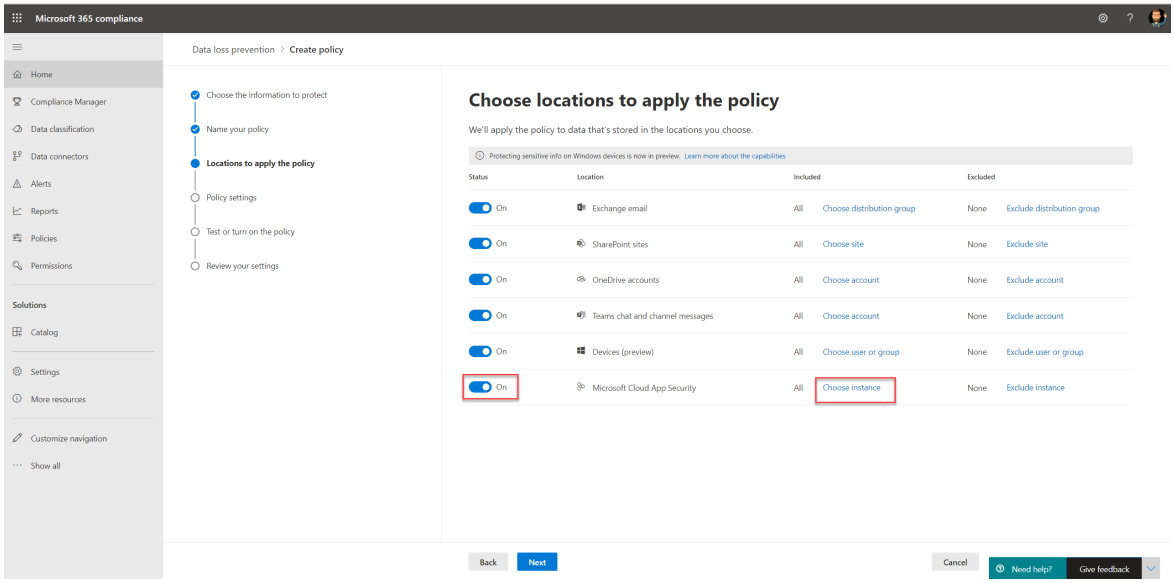
After you connect your cloud apps to Cloud App Security, you can create Microsoft 365 DLP policies for them.

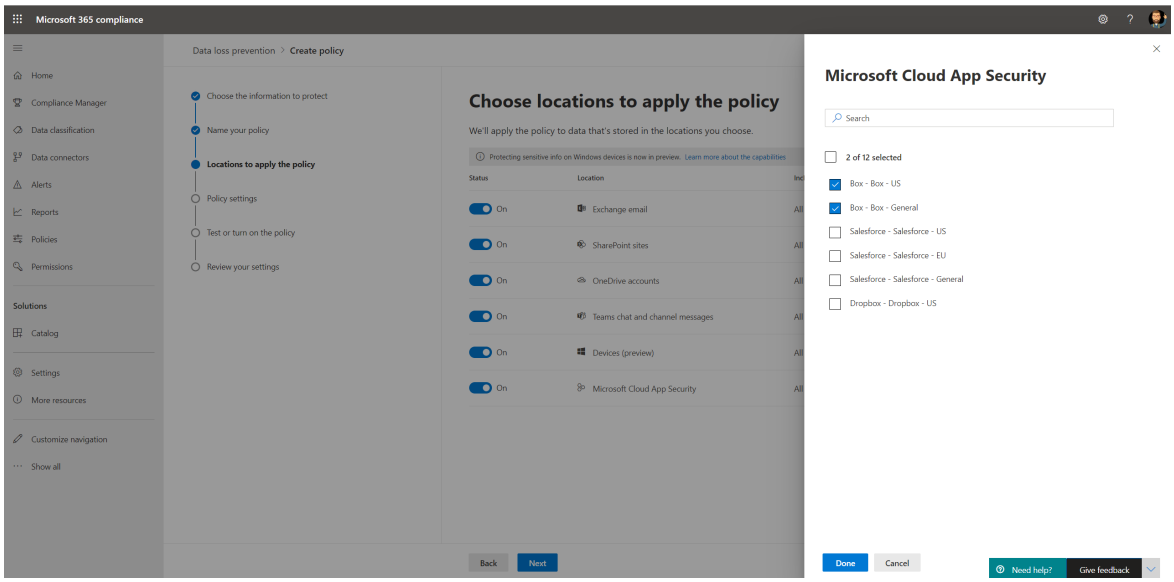
> **NOTE**
> It's also possible to use Microsoft Cloud App Security to create DLP policies to Microsoft cloud apps. However, it's recommended to use Microsoft 365 to create and manage DLP policies to Microsoft cloud apps.

Create a DLP policy to a non-Microsoft cloud app

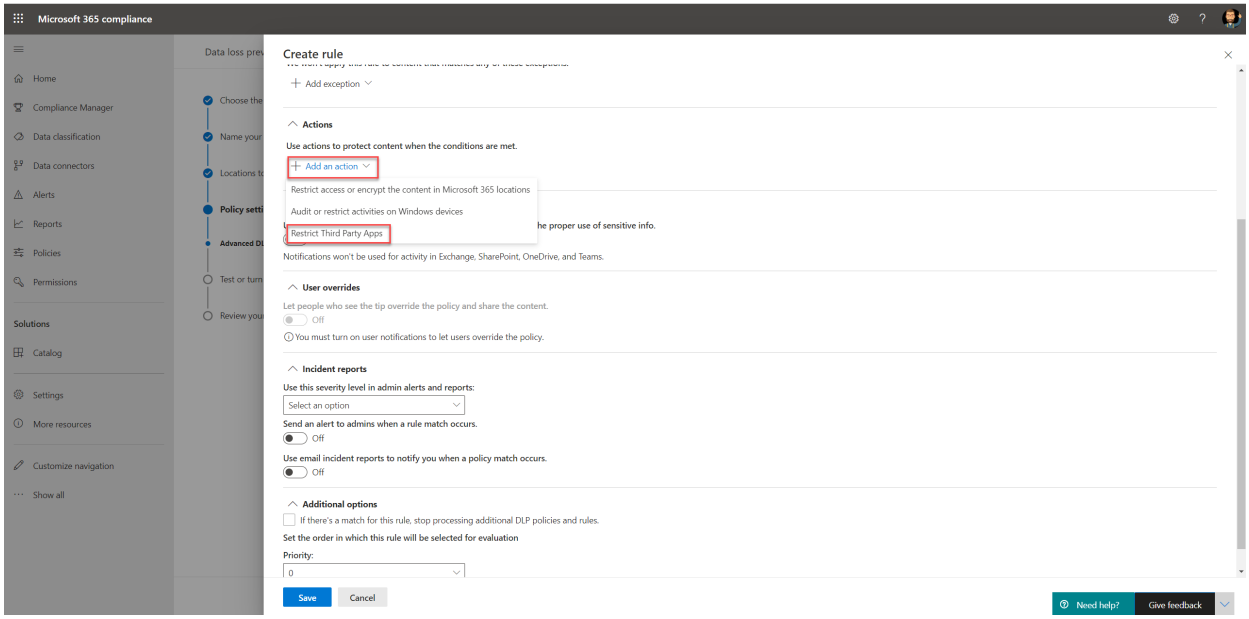
When you select a location for the DLP policy, turn on the **Microsoft Cloud App Security** location.

- To select a specific app or instance, select **Choose instance**.
- If you don't select an instance, the policy uses all connected apps in your Microsoft Cloud App Security tenant.

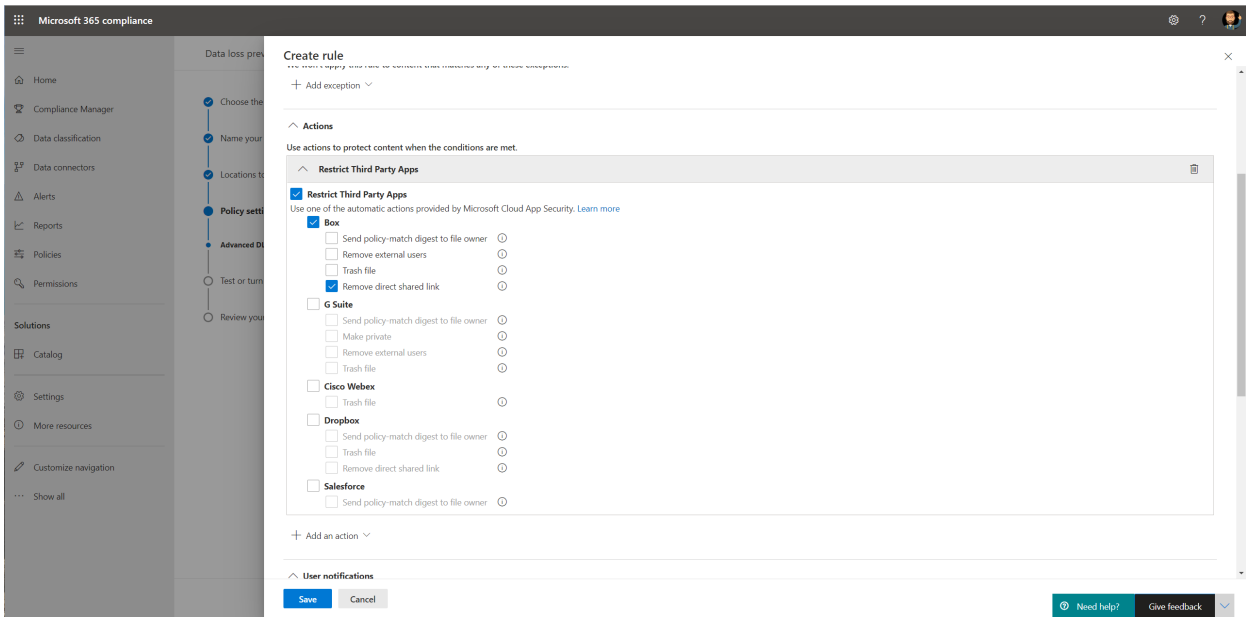




You can choose various actions for every supported non-Microsoft cloud app. For every app, there are different possible actions (depends on the cloud app API).



When you create a rule in the DLP policy, you can select an action for non-Microsoft cloud apps. To restrict third-party apps, select **Restrict Third Party Apps**.



For information about creating and configuring DLP policies, see Create test and tune a DLP policy.

DLP policy conditions, exceptions, and actions (preview)

2/18/2021 • 8 minutes to read • Edit Online

Conditions and exceptions in DLP policies identify sensitive items that the policy is applied to. Actions define what happens as a consequence of a condition of exception being met.

- Conditions define what to include
- Exceptions define what to exclude.
- Actions define what happens as a consequence of condition or exception being met

Most conditions and exceptions have one property that supports one or more values. For example, if the DLP policy is being applied to Exchange emails, the **The sender** is condition requires the sender of the message. Some conditions have two properties. For example, the **A message header includes any of these words** condition requires one property to specify the message header field, and a second property to specify the text to look for in the header field. Some conditions or exceptions don't have any properties. For example, the **Attachment is password protected** condition simply looks for attachments in messages that are password protected.

Actions typically require additional properties. For example, when the DLP policy rule redirects a message, you need to specify where the message is redirected to.

Conditions and exceptions for DLP policies

The tables in the following sections describe the conditions and exceptions that are available in DLP.

- Senders
- Recipients
- Message subject or body
- Attachments
- Message headers
- Message properties

Senders

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Sender is	condition: *From* exception: *ExceptIfFrom*	Addresses	Messages that are sent by the specified mailboxes, mail users, mail contacts, or Microsoft 365 groups in the organization.
Sender IP address is	condition: *SenderIPRanges* exception: *ExceptIfSenderIPRanges*	IPAddressRanges	Messages where the sender's IP address matches the specified IP address, or falls within the specified IP address range.

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Sender address contains words	condition: *FromAddressContainsWords* exception: *ExceptIfFromAddressContainsWords*	Words	Messages that contain the specified words in the sender's email address.
Sender address matches patterns	condition: *FromAddressMatchesPatterns* exception: *ExceptFromAddressMatchesPatterns*	Patterns	Messages where the sender's email address contains text patterns that match the specified regular expressions.
Sender domain is	condition: *SenderDomainIs* exception: *ExceptIfSenderDomainIs*	DomainName	Messages where the domain of the sender's email address matches the specified value. If you need to find sender domains that *contain* the specified domain (for example, any subdomain of a domain), use **The sender address matches**(*FromAddressMatchesPatterns*) condition and specify the domain by using the syntax: '.domain.com$'.
Sender scope	condition: *FromScope* exception: *ExceptIfFromScope*	UserScopeFrom	Messages that are sent by either internal or external senders.

Recipients

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Recipient is	condition: *SentTo* exception: *ExceptIfSentTo*	Addresses	Messages where one of the recipients is the specified mailbox, mail user, or mail contact in the organization. The recipients can be in the **To**, **Cc**, or **Bcc** fields of the message.
Recipient domain is	condition: *RecipientDomainIs* exception: *ExceptIfRecipientDomainIs*	DomainName	Messages where the domain of the sender's email address matches the specified value.

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Recipient address contains words	condition: *RecipientAddressContainsWords* exception: *ExceptIfRecipientAddressContainsWords*	Words	Messages that contain the specified words in the recipient's email address. **Note**: This condition doesn't consider messages that are sent to recipient proxy addresses. It only matches messages that are sent to the recipient's primary email address.
Recipient address matches patterns	condition: *RecipientAddressMatchesPatterns* exception: *ExceptIfRecipientAddressMatchesPatterns*	Patterns	Messages where a recipient's email address contains text patterns that match the specified regular expressions. **Note**: This condition doesn't consider messages that are sent to recipient proxy addresses. It only matches messages that are sent to the recipient's primary email address.
Sent to member of	condition: *SentToMemberOf* exception: *ExceptIfSentToMemberOf*	Addresses	Messages that contain recipients who are members of the specified distribution group, mail-enabled security group, or Microsoft 365 group. The group can be in the **To**, **Cc**, or **Bcc** fields of the message.

Message subject or body

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Subject contains words or phrases	condition: *SubjectContainsWords* exception: *ExceptIf SubjectContainsWords*	Words	Messages that have the specified words in the Subject field.
Subject matches patterns	condition: *SubjectMatchesPatterns* exception: *ExceptIf SubjectMatchesPatterns*	Patterns	Messages where the Subject field contain text patterns that match the specified regular expressions.
Content contains	condition: *ContentContainsSensitiveInformation* exception *ExceptIfContentContainsSensitiveInformation*	SensitiveInformationTypes	Messages or documents that contain sensitive information as defined by data loss prevention (DLP) policies.

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Subject or Body matches pattern	condition: *SubjectOrBodyMatchesPatterns* exception: *ExceptIfSubjectOrBodyMatchesPatterns*	Patterns	Messages where the subject field or message body contains text patterns that match the specified regular expressions.
Subject or Body contains words	condition: *SubjectOrBodyContainsWords* exception: *ExceptIfSubjectOrBodyContainsWords*	Words	Messages that have the specified words in the subject field or message body

Attachments

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Attachment is password protected	condition: *DocumentIsPasswordProtected* exception: *ExceptIfDocumentIsPasswordProtected*	none	Messages where an attachment is password protected (and therefore can't be scanned). Password detection only works for Office documents, .zip files, and .7z files.
Attachment's file extension is	condition: *ContentExtensionMatchesWords* exception: *ExceptIfContentExtensionMatchesWords*	Words	Messages where an attachment's file extension matches any of the specified words.
Any email attachment's content could not be scanned	condition: *DocumentIsUnsupported* exception: *ExceptIfDocumentIsUnsupported*	n/a	Messages where an attachment isn't natively recognized by Exchange Online.
Any email attachment's content didn't complete scanning	condition: *ProcessingLimitExceeded* exception: *ExceptIfProcessingLimitExceeded*	n/a	Messages where the rules engine couldn't complete the scanning of the attachments. You can use this condition to create rules that work together to identify and process messages where the content couldn't be fully scanned.

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Document name contains words	condition: *DocumentNameMatchesWords* exception: *ExceptIfDocumentNameMatchesWords*	Words	Messages where an attachment's file name matches any of the specified words.
Document name matches patterns	condition: *DocumentNameMatchesPatterns* exception: *ExceptIfDocumentNameMatchesPatterns*	Patterns	Messages where an attachment's file name contains text patterns that match the specified regular expressions.
Document property is	condition: *ContentPropertyContainsWords* exception: *ExceptIfContentPropertyContainsWords*	Words	Messages or documents where an attachment's file extension matches any of the specified words.
Document size equals or is greater than	condition: *DocumentSizeOver* exception: *ExceptIfDocumentSizeOver*	Size	Messages where any attachment is greater than or equal to the specified value.

Message Headers

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Header contains words or phrases	condition: *HeaderContainsWords* exception: *ExceptIfHeaderContainsWords*	Hash Table	Messages that contain the specified header field, and the value of that header field contains the specified words.
Header matches patterns	condition: *HeaderMatchesPatterns* exception: *ExceptIfHeaderMatchesPatterns*	Hash Table	Messages that contain the specified header field, and the value of that header field contains the specified regular expressions.

Message properties

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION

CONDITION OR EXCEPTION IN DLP	CONDITION/EXCEPTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Message size over	condition: *MessageSizeOver* exception: *ExceptIfMessageSizeOver*	Size	Messages where the total size (message plus attachments) is greater than or equal to the specified value. **Note**: Message size limits on mailboxes are evaluated before mail flow rules. A message that's too large for a mailbox will be rejected before a rule with this condition is able to act on the message.
With importance	condition: *WithImportance* exception: *ExceptIfWithImportance*	Importance	Messages that are marked with the specified importance level.
Content character set contains words	condition: *ContentCharacterSetContainsWords* *ExceptIfContentCharacterSetContainsWords*	CharacterSets	Messages that have any of the specified character set names.
Has sender override	condition: *HasSenderOverride* exception: *ExceptIfHasSenderOverride*	n/a	Messages where the sender has chosen to override a data loss prevention (DLP) policy. For more information about DLP policies see Data loss prevention.
Message type matches	condition: *MessageTypeMatches* exception: *ExceptIfMessageTypeMatches*	MessageType	Messages of the specified type.

Actions for DLP policies

This table describes the actions that are available in DLP.

ACTION IN DLP	ACTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION

ACTION IN DLP	ACTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Set header	SetHeader	First property: *Header Name* Second property: *Header Value*	The SetHeader parameter specifies an action for the DLP rule that adds or modifies a header field and value in the message header. This parameter uses the syntax "HeaderName:HeaderValue". You can specify multiple header name and value pairs separated by commas
Remove header	RemoveHeader	First property: *MessageHeaderField* Second property: *String*	The RemoveHeader parameter specifies an action for the DLP rule that removes a header field from the message header. This parameter uses the syntax “HeaderName” or "HeaderName:HeaderValue". You can specify multiple header names or header name and value pairs separated by commas
Redirect the message to specific users	*RedirectMessageTo*	Addresses	Redirects the message to the specified recipients. The message isn't delivered to the original recipients, and no notification is sent to the sender or the original recipients.
Forward the message for approval to sender’s manager	Moderate	First property: *ModerateMessageByManager* Second property: *Boolean*	The Moderate parameter specifies an action for the DLP rule that sends the email message to a moderator. This parameter uses the syntax: @{ModerateMessageByManager = <$true | $false>;
Forward the message for approval to specific approvers	Moderate	First property: *ModerateMessageByUser* Second property: *Addresses*	The Moderate parameter specifies an action for the DLP rule that sends the email message to a moderator. This parameter uses the syntax: @{ ModerateMessageByUser = @("emailaddress1","emailaddress2",..."emailaddressN")}

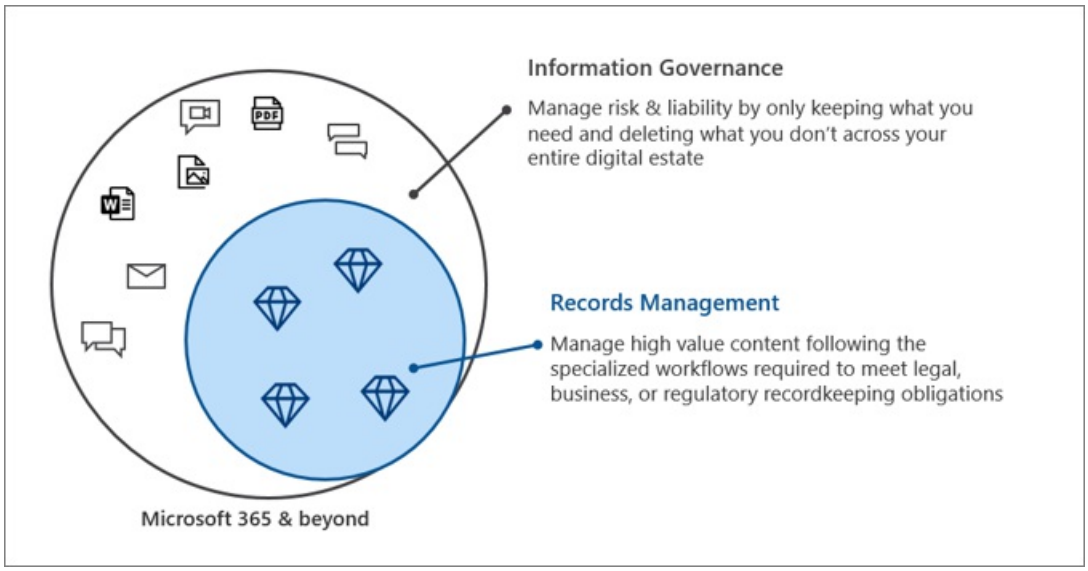
ACTION IN DLP	ACTION PARAMETERS IN MICROSOFT 365 POWERSHELL	PROPERTY TYPE	DESCRIPTION
Add recipient	AddRecipients	First property: *Field* Second property: *Addresses*	Adds one or more recipients to the To/Cc/Bcc field of the message. This parameter uses the syntax: @{<AddToRecipients | CopyTo | BlindCopyTo> = "emailaddress"}
Add the sender's manager as recipient	AddRecipients	First property: *AddedManagerAction* Second property: *Field*	Adds the sender's manager to the message as the specified recipient type (To, Cc, Bcc), or redirects the message to the sender's manager without notifying the sender or the recipient. This action only works if the sender's Manager attribute is defined in Active Directory. This parameter uses the syntax: @{AddManagerAsRecipientType = "<To | Cc | Bcc>"}
Prepend subject	PrependSubject	String	Adds the specified text to the beginning of the Subject field of the message. Consider using a space or a colon (:) as the last character of the specified text to differentiate it from the original subject text. To prevent the same string from being added to messages that already contain the text in the subject (for example, replies), add the "The subject contains words" (ExceptIfSubjectContainsWords) exception to the rule.
Apply HTML disclaimer	ApplyHtmlDisclaimer	First property: *Text* Second property: *Location* Third property: *Fallback action*	Applies the specified HTML disclaimer to the required location of the message. This parameter uses the syntax: @{ Text = " " ; Location = <Append | Prepend>; FallbackAction = <Wrap | Ignore | Reject> }

Microsoft Information Governance in Microsoft 365

2/18/2021 • 2 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

Use Microsoft Information Governance (sometimes abbreviated to MIG) capabilities to govern your data for compliance or regulatory requirements.



Looking to protect your data? See Microsoft Information Protection in Microsoft 365.

Information governance

To keep what you need and delete what you don't:

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Retention policies and retention labels	Retain or delete content with policy management and a deletion workflow for email, documents, instant messages, and more Example scenario: Apply a retention label to content automatically	Get started with retention policies and retention labels
Import service	Bulk-import PST files to Exchange Online mailboxes to retain and search email messages for compliance or regulatory requirements	Use network upload to import your organization's PST files to Microsoft 365
Archive third-party data	Import, archive, and apply compliance solutions to third-party data from social media platforms, instant messaging platforms, and document collaboration platforms	Third-party connectors
Inactive mailboxes	Retain mailbox content after employees leave the organization	Create and manage inactive mailboxes

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED

Records management

To manage high-value content for legal, business, or regulatory obligations:

CAPABILITY	WHAT PROBLEMS DOES IT SOLVE?	GET STARTED
Records management	A single solution for email and documents that incorporates retention schedules and requirements into a file plan that supports the full lifecycle of your content with records declaration, retention, and disposition Example scenario: Disposition of records	Get started with records management

Learn about retention policies and retention labels

2/18/2021 • 24 minutes to read • Edit Online

Microsoft 365 licensing guidance for security & compliance.

For most organizations, the volume and complexity of their data is increasing daily—email, documents, instant messages, and more. Effectively managing or governing this information is important because you need to:

- **Comply proactively with industry regulations and internal policies** that require you to retain content for a minimum period of time—for example, the Sarbanes-Oxley Act might require you to retain certain types of content for seven years.
- **Reduce your risk in the event of litigation or a security breach** by permanently deleting old content that you're no longer required to keep.
- **Help your organization to share knowledge effectively and be more agile** by ensuring that your users work only with content that's current and relevant to them.

Retention settings that you configure can help you achieve all these goals. Managing content commonly requires two actions:

- **Retaining** content so that it can't be permanently deleted before the end of the retention period.
- **Deleting** content permanently at the end of the retention period.

With these two retention actions, you can configure retention settings for the following outcomes:

- Retain-only: Retain content forever or for a specified period of time.
- Delete-only: Delete content after a specified period of time.
- Retain and then delete: Retain content for a specified period of time and then delete it.

These retention settings work with content in place that saves you the additional overheads of creating and configuring additional storage when you need to retain content for compliance reasons. In addition, you don't need to implement customized processes to copy and synchronize this data.

How retention settings work with content in place

When content has retention settings assigned to it, that content remains in its original location. People can continue to work with their documents or mail as if nothing's changed. But if they edit or delete content that's included in the retention policy, a copy of the content is automatically retained.

- For SharePoint and OneDrive sites: The copy is retained in the **Preservation Hold** library.
- For Exchange mailboxes: The copy is retained in the **Recoverable Items** folder.
- For Teams and Yammer messages: The copy is retained in a hidden folder named **SubstrateHolds** as a subfolder in the Exchange **Recoverable Items** folder.

> **NOTE**
> The Preservation Hold library consumes storage that isn't exempt from a site's storage quota. You might need to increase your storage when you use retention settings for SharePoint and Microsoft 365 groups.

These secure locations and the retained content are not visible to most people. In most cases, people do not even need to know that their content is subject to retention settings.

For more detailed information about how retention settings work for different workloads, see the following articles:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Microsoft Teams
- Learn about retention for Yammer
- Learn about retention for Exchange

Retention policies and retention labels

To assign your retention settings to content, use **retention policies** and **retention labels with label policies**. You can use just one of these methods, or combine them.

Use a retention policy to assign the same retention settings for content at a site or mailbox level, and use a retention label to assign retention settings at an item level (folder, document, email).

For example, if all documents in a SharePoint site should be retained for 5 years, it's more efficient to do this with a retention policy than apply the same retention label to all documents in that site. However, if some documents in that site should be retained for 5 years and others retained for 10 years, a retention policy wouldn't be able to do this. When you need to specify retention settings at the item level, use retention labels.

Unlike retention policies, retention settings from retention labels travel with the content if it's moved to a different location within your Microsoft 365 tenant. In addition, retention labels have the following capabilities that retention policies don't support:

- Options to start the retention period from when the content was labeled or based on an event, in addition to the age of the content or when it was last modified.
- Use trainable classifiers to identify content to label.
- Apply a default label for SharePoint documents.
- Support disposition reviewto review the content before it's permanently deleted.
- Mark the content as a record as part of the label settings, and always haveproof of dispositionwhen content is deleted at the end of its retention period.

Retention policies

Retention policies can be applied to the following locations:

- Exchange email
- SharePoint site
- OneDrive accounts
- Microsoft 365 Groups
- Skype for Business
- Exchange public folders
- Teams channel messages
- Teams chats
- Yammer community messages
- Yammer private messages

You can very efficiently apply a single policy to multiple locations, or to specific locations or users.

For the start of the retention period, you can choose when the content was created or, supported only for files

and the SharePoint, OneDrive, and Microsoft 365 Groups locations, when the content was last modified.

Items inherit the retention settings from their container specified in the retention policy. If they are then moved outside that container when the policy is configured to retain content, a copy of that item is retained in the workload's secured location. However, the retention settings don't travel with the content in its new location. If that's required, use retention labels instead of retention policies.

Retention labels

Use retention labels for different types of content that require different retention settings. For example:

- Tax forms that need to be retained for a minimum period of time.
- Press materials that need to be permanently deleted when they reach a specific age.
- Competitive research that needs to be retained for a specific period and then permanently deleted.
- Work visas that must be marked as a record so that they can't be edited or deleted.

In all these cases, retention labels let you apply retention settings for governance control at the item level (document or email).

With retention labels, you can:

- **Enable people in your organization to apply a retention label manually** to content in Outlook and Outlook on the web, OneDrive, SharePoint, and Microsoft 365 groups. Users often know best what type of content they're working with, so they can classify it and have the appropriate retention settings applied.
- **Apply retention labels to content automatically** if it matches specific conditions, such as when the content contains:
  - Specific types of sensitive information.
  - Specific keywords that match a query you create.
  - Pattern matches for a trainable classifier.
